This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

PASSING EVENTS.

Reasonable Proposals.

Automobilists have made out their "articles of faith" to which Members of Parliament are to subscribe as a condition of securing automobile support at the coming General Election, and in the advertisement pages (page xvii.) of the current issue a form appears with these questions properly set out, in such shape that any of our readers can easily remove it, if opportunity serves to induce a prospective candidate to subscribe his signature. If we get a good number of Members in the coming House of Commons who have pledged themselves to these three provisions, the prospects of automobilism in the future should be satisfactory. It is well to remember, however, that there is another side to the question. We do not mean merely the hostile side, but the side of people who really have legitimate rights on the high road. From this point of view we note, with full approval, that the Cyclists' Touring Club and the National Cyclists' Union are also endeavouring to enlist the good offices of intending candidates for Parliament on behalf of legislation which will be :—

(1) An Act rendering it compulsory for all vehicles to carry lights at night.

(2) An amendment of the Motor Car Acts, whereby greater protection may be afforded to cyclists and other road users on the King's highway, and

(3) An improvement in our methods of road administration.

At the same time these well organised bodies are supporting amendments to the existing motor car law, chief amongst which is that it shall be made penal for any motor car driver to go round a corner on the wrong side, unless his view is open and unobstructed. The first proposal given above we have always been in favour of and we will certainly be glad to see the cyclists successful in preventing what we have always considered one of the greatest possible abuses of the road, this dangerous method of rounding corners ; in fact, we would even go further than they do and make it illegal for any vehicle to round a corner on the wrong side, whether there is a clear view or not, unless some very special circumstances render it unavoidable.

Commercial Motor Boat Development.

The promise of the Government to introduce at an early date legislation designed to improve the value of our canals as a means of transport and communication, on which we commented a short while ago, may almost be said to synchronise with some very important experiments now being conducted under the auspices of Messrs. Thornycroft and Co. on the application of the suction producer to boat propulsion. The principle involved in the suction producer has been made familiar to all our readers. It may be shortly described as an invention by means of which an internal-combustion engine is able to make its own gas from coke or anthracite as it requires it, and the resulting motive power, needless to say, is remarkable for its cheapness. Messrs. Thornycroft and Co. have been conducting experiments on the Thames with a motor barge fitted with the Capitaine suction producer, and now this barge is to be tested in carrying freight from point to point along our system of inland canals under regular working mercantile conditions. A start was made from Brentford on Tuesday morning with a regular cargo which is to be delivered somewhere near Birmingham or Wolverhampton, and the motor-driven barge is to ply exactly under similar conditions to those which prevail in the case of horse-pulled canal barges. There is no more trying labour for the horse than canal work. It is collar work all the time, so that all true lovers of the equine race will be delighted to find this heaviest of his labours taken over by the motor boat.

◆ ◆ ◆

A Splendid Opening.

The list of places between which it is intended the motor barge should convey cargoes includes important Midland towns between London and Birmingham, and between Birmingham, Chester and Manchester, connecting up such places as Stoke-upon-Trent, Banbury and Oxford, to mention only a few of those which will be touched. These few names suggest what a splendid network of canals we possess, and how absurd it is that they should be so largely permitted to fall into disuse, and are only employed for transport under the antiquated conditions provided by the horse and the tow-rope. With effective legislation of the kind promised, and the success of the suction producer, which we do not doubt will be proved before long, the development of canal transport ought in a very short time to amount to an important national asset.

A Proper Way to go to Work.

The administration of our highways and the methods of repairing them have been the subject of denunciation, indignation, vituperation, humorous banter, and persiflage for many years past. In spite of this and the energetic propaganda of the Roads Improvement Association, in spite of progressive district and county surveyors scattered here and there (alas! few and far between), the administration, such as it is, yet remains unaltered, and things muddle along in their old chaotic way. Nothing in the chaotic jumble has been more characteristic than the total absence of any scientific method in the selection of the materials with which the roads are repaired. There is not even any uniformity in the size to which the road metal is crushed, let alone any attempts to adapt different kinds of rock to different local requirements. It is therefore with lively satisfaction that all interested in road improvement, and automobilists, needless to say, lead opinion in this respect, will welcome the efforts made by the Corporation of Hornsey to obtain some reliable information as to the comparative values of different rocks for road-mending purposes. In order to obtain the services of experts on the problem, the Corporation approached the Board of Education, with the result that Dr. J. S. Flett and Mr. J. A. Howe, of the Museum of Practical Geology, Jermyn Street, assisted the Corporation in making a petrological examination of the rocks subjected to tests on the road. A regular collection of materials has, as a result, been assembled at Jermyn Street, including upwards of a hundred different specimens of road-mending stone. The rocks have been subjected to the mechanical attrition test both in the dry and wet condition, and the results noted so as to enable comparison between the different kinds of rock to be established. Scientific investigation of this kind must obviously, if carried out on a sufficiently extensive scale, prove ultimately of the highest value both in improving the general surface of our roads, and in saving cost in road upkeep. To employ expensive and high-class road material in some places is practically to throw it away ; to use cheap and inferior material in others where the traffic is severe is to incur great additional expense and shocking deterioration of the road surface. Of course, one swallow does not make a summer, and the adoption of scientific methods by one local authority cannot be expected to effect much, but it is a beginning which one may hope to see generally followed, so that when, in the near future, highway management becomes, as we trust it will be, centralised, scientific results may be available for the use of the central authority.

The Melbourne-Sydney Reliability Trial.

Someone who is assumed to have been a philosopher was credited with saying that the general civilisation of a community may be gauged by the state of their roads and their treatment of foreigners. As far as the great Australian Republic is concerned, they most completely disprove the alleged philosopher's observation, for by common consent of motorists and others their roads are positively shocking. More shocking even, or, at any rate, quite as shocking as those interruptions in the landscape which pass by that name in America. At the same time they provide a magnificent testing ground for motors. Motors which can go through an extended trial on those roads and emerge—we will not say unscathed, but holding together, require no further certificate of reliability, and the hair-breadth escapes which tearing over them provides added enormously to the hilarity of everybody who took part in the Melbourne-Sydney reliability contest, of which we give a full account elsewhere. There were plenty of additional obstacles, in the way of "V"-shaped gulleys across the roads, similar to the French *cannivaux*, but here they were less painfully noticed, because the contrast, even the bumps which they occasioned, in comparison with the rest of the road, was far less noticeable than in France. The competition was not in any way intended for a race, but it more or less degenerated or developed into a race, owing to the quaint arrangement by which the reliability trial competitors were allowed to make up by mere high speed for delays caused by breakdowns. However, the object of the function was to amuse and interest the population in the automobile, and in this it most admirably succeeded, for probably no automobile event was ever the occasion of more unalloyed enjoyment and fun, to participants, to competitors, and to the public than this. The public, in fact, developed a perfect mania for speed, and the faster the cars went and the worse the roads were the more they were delighted. One small town that was provided by nature, or the neglect of the local authorities, with a particularly shocking stretch of road, made an application that a car might be run at maximum speed over it to amuse the populace. The request was granted, the car survived, nobody was killed, and even the police did not interfere. The trial was not entirely in the hands of the trade. Among the competitors were representatives of some of the wealthiest families in the colony, together with many a veteran cycle rider. The motorist of the Antipodes is quite as good at a yarn as his colleague nearer home, and the awesome stories, principally zoological, of the number of rabbits spificated by cars, of kangaroos who raced them on either side of the route, of snakes that wound round their wheels and countershafts, and of monstrous lizards, locally known as iguanas, who calmly stood and stared the competitors out of countenance, till even the most hardened automobilist drove on one side as if he had met a Surrey policeman, might for sheer truthfulness have been extracts from a company promoter's affidavit. Some of the speed performances were truly wonderful, and one of the sights of the whole function was to see a big Mercedes tearing down Money Money Hill, past its danger board and dangerous turns and shocking surface, without an accident happening; and how the competitors made their way in the dark at twenty miles an hour, as they did do, over some of the tracks they encountered, still remains a mystery. In spite of all the troubles and dangers, however, the best of humour prevailed, and this was not diminished when, at close of day, it was found (in conversation) that no less than ten different competitors had all run over and flattened out the same giant snake at the same cross roads, and all described in similar language how it hissed and spat as the wheels went over it. Its original discoverer, who came across it dead, had, it may be explained, carefully "placed" it by the wayside coiled up on the grass, with a few feet of its length protruding on to the road.

"Direct-Drive": Is it a Monopoly?

Many of our readers will call to mind the uneasiness which prevailed in the automobile world generally when, in the year 1900, an attempt was made to maintain the Maybach carburettor patent as conferring a monopoly on its holders of all float-feed carburettors in use on motor cars. The attempt failed dismally, for the patent was declared invalid in the Court of First Instance; there was no appeal, and the British Motor Traction Company, which owned it, went into liquidation. At the present moment there is talk of a claim to a somewhat similar monopoly as being got up by the holders of the Renault patent, of which we gave a descriptive article the week before last. As will be seen from our correspondence columns, our article has evoked a letter from the Duryea Company, and we have also had a patent, taken out by Whitney in 1898 (No. 10,020) brought before our notice by Messrs. Gedge and Feeny, who cite it as an anticipation of the Renault invention. We do not propose to adopt the highly improper attitude of pronouncing an opinion on the validity of any patent which may or may not become at an early date the subject of litigation, though we are bound to admit that the Whitney patent, which, by the way, has been allowed to lapse, contains elements which very closely resemble those in the Renault, since both inventions include the use of live-axles driven by propeller shafts, and of change-speed-gearing that gives a "direct-drive" on the top speed. We do not, however, attach any importance to the American patent to which the Duryea Company apparently refer (we believe it to be No. 540,648, June 11th, 1895) for the car therein described and illustrated neither has a propeller-shaft with universal-joints, nor is a "direct-drive" provided for on any "speed."

In any case, however, it may confidently be predicted that, as in the case of the Maybach carburettor, neither manufacturers nor car users in this country are at all likely to acquiesce tamely in any attempt to set up a monopoly for some form of construction already adopted in the great majority of motor cars, without combining and making a tough fight of it. Already we notice that the Argyll Company, in sending a donation of £20 to the British Empire Motor Trades Alliance recently, offered to increase that amount to £100 if such litigation should arise.

MELBOURNE-SYDNEY RELIABILITY CONTEST.

TWICE during last year long distance trials for cars and cycles were organised by the Dunlop Company between Melbourne and Sydney. The start of the first test was from Sydney on February 21st, the run terminating on February 25th. In the November contest, however, the course was reversed, the start being from Melbourne on November 14th, the finish on November 18th being at Sydney—the full distance in each case totalling to 572 miles. The best time made in February was by H. L. Stevens, 23h. 42m., on a 12-h.p. Darracq, this time being bettered only by one in the November run, viz., by G. Hobbs, on an 18–28-h.p. Mercedes, 21h. 44m. H. L. Stevens, this time driving a 15-h.p. Darracq, was second best with 24h. 58m. H. Tarrant, who in February scored full points and second best with a 12-h.p. Argyll in 31h. 48½m., this time drove an 8–10-h.p. Tarrant, an Australian car built in Melbourne, securing full marks and making the time of 30h. 4½m. The winners were: Class A, 8-h.p. De Dion (full points); time, 33h. 20½m. Class C, 18–28-h.p. Mercedes (full points); time, 21h. 44m. Class D (cycles), 3½-h.p., Brown; time, 26h. 59½m. In Class B, no less than 5 cars tied with full points, these being a 10-h.p. Argyll, a 10-h.p. De Dion, a 12-h.p. Richard-Brasier, a 10–12-h.p. Talbot, and the 8–10-h.p. Tarrant. Under the rules these cars and the other "full pointers" therefore had to continue to run off further tests to decide the winner and holder of the Dunlop Trophy. The detailed times for each day, the total marks, and times, &c., are given in our table.

In the car section of the 29 entrants, 25 started on November 14th, and 8 cycles were despatched out of the 10 entrants. The course, as before, was the old coach road, and enthusiasm ran high amongst the country folk, who gathered at the wayside to cheer on the competitors. In the towns enormous crowds were drawn together to enjoy what must have been a similar experience to that which was afforded in Great Britain to the many thousands who made holiday to see the cars pass along in the now historical "1,000 Miles Trial."

Incidents were numerous throughout the trial. On the first day's run, the contestants were sent from the Haymarket, at Melbourne, early in the morning, and the excitement of the event caused a huge crowd of people to assemble and witness the cars leave on their trial. Mr. Foy, who had entered a Panhard car, did not start, because the Hon. Mrs. Bolder-Sykes, who was to drive, had not arrived from England in time. Mr. Hobbs' Mercedes was one of the fastest away from the mark, but nearly all the cars exhibited a remarkable turn of speed, for although the trial was strictly speaking a reliability contest, yet for the most part the competitors turned up in racing trim. Mr. Foster's 50-h.p. Talbot car, which he specially obtained to take part in the trial, was disabled through a crack in the water-jacket, which only made itself noticed as it was trying to overhaul the Mercedes just after the start. Some twenty miles on the northern side of Euroa, Mr. M'Kenzie's car broke its front axle in passing over one of the many dangerous V-shaped culverts, but the owner, being of a practical turn of mind, managed to effect repairs of a sort, which enabled him to drive into Euroa within the time limit—thus scoring full marks for that portion of the run. Tyre troubles were numerous in the original contest, it will be remembered, and it was not long before there was a heavy crop on this run also. Mr. Kellow was frequently delayed through this cause, and not being able

MELBOURNE-SYDNEY RELIABILITY TRIAL, November 14–18.—S. Day on his 8-h.p. De Dion car, the winner in the single cylinder class and of the Robert Hurst Trophy.

to reach that night's destination until 10 o'clock, he, consequently, obtained no marks for the journey. An exciting time befell the Pressmen, who were accommodated in a special car, and they ended their weird experiences by having to run ten miles in the dark, without lights, over a "road" which might more correctly have been termed a bush track; in fact, from Seymour the roads were abominable, always extremely rough, often made dangerous by deep ruts, and occasionally studded with tree-stumps.

Fair weather also favoured the competitors on the second day, and all started for Albury, just over 100 miles distant, in high spirits. Mr. M'Kenzie had his damaged axle repaired immediately after taking his car from the control, and by this he lost 97 minutes. In order to secure full marks under the regulations, by arriving at Albury within the time limit, he had to average 28 miles an hour, and it was while travelling at somewhat over this speed that his axle broke again in the place where it had been brazed. Once more he spliced it, and once more also was he able to reach his destination; on arrival he once more called in the help of a blacksmith, who spoiled the axle entirely in attempting to repair it, the car having, therefore, to be sent back to Mr. M'Kenzie's home by rail. An incident in Mr. Stevens' ride, on this day, was the charging of a railway gate near Wodonga; the level crossing was situated in the bend of the road, one gate was partly opened, the other closed, but both were carried away by Mr. Stevens' Darracq, which he was unable to pull up in time. Neither of the occupants were hurt, however, and the only damage which the car sustained was a slightly-bent front axle. This same crossing nearly caused Mr. Little to come to grief, for he was all but caught by a passing train. Engine troubles were experienced by Mr. Cox and Mr. Bolger, who each lost 24 marks through this cause. Mr. Kellow, who had decided the previous night to go no further than Albury, retired from the contest, and returned to Melbourne by road on the following day. What must have been an amusing incident—except for those who took part in it—was the occasion on which the De Dion and Argyll cars, driven by Mr. S. Day and Mr. W. R. Grimwade respectively, ran into a swarm of bees, which promptly settled themselves on the passengers with the usual result.

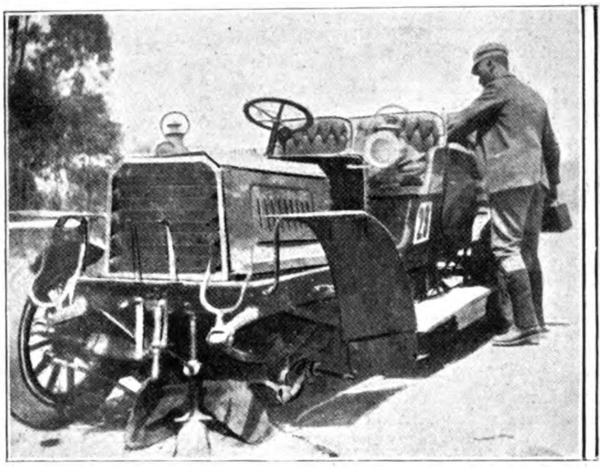
MELBOURNE-SYDNEY RELIABILITY TRIAL COMPETITORS AND OFFICIALS.

Millions of rabbits swarmed in droves along the hillsides of the country through which the cars passed during the third day's run. Many of them were also encountered on the roads, and so much curiosity did they exhibit in the approaching vehicles that some of them even forgot to get out of the way. Bad luck befell Mr. Arnott's Innes car near Mullengandra, for the near side front wheel was fractured in passing over some heavy sand just after crossing the bridge at that place. So much wrecked was the wheel that repair seemed out of the question, and a wagon was telegraphed for. To pass the time, however, Mr. Arnott experimented with some pieces of wood which he bolted across between the felloes, and he found that these, together with four of the least damaged spokes, were capable of supporting the car, so they continued the journey, and arrived at Gundagai only a little over three and half hours late. Mr. Fauvell's Richard-Brasier car broke a spring, but this also was repaired, and the car came in two hours late. A damaged steering-gear delayed Mr. Rand for an hour before he left Albury, and he lost seventy minutes on the road through punctures. Mr. Wittber's Wolseley also sustained damage to its steering-gear in passing over a rut, while Mr. Holmes experienced no less than three hours' delay on account of a choked carburettor and an over-heated brake.

There was never much of the steady-going reliability contest about this competition, and what little there was ultimately disappeared before the request of the authorities of Yass, who telegraphed asking that the first car to arrive there should run through the town at full speed in order that the residents might see what real speed was like. The streets were accordingly kept clear, and in due course Mr. Hobbs delighted the spectators by running through their township "at the rate of 45." Mr. Arnott was again unfortunately delayed, for his previous accident had affected the radiator of his car and its defect caused him considerable delay during this part of the run. Mr. Wittber was another competitor who had that common complaint of the district—a broken axle; he was able, however, to get it repaired by a local blacksmith at Yass, and he endeavoured to make up for lost



J. M. Arnott's smash at Mullengandra, near Albury.

Arnott's car, showing the repair to his wheel with hard wood, obtained from a farmhouse.

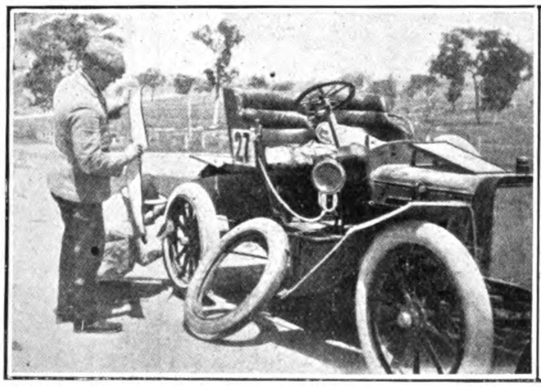
MELBOURNE-SYDNEY RELIABILITY TRIAL, November 14–18.

time by an average speed of about 28 miles an hour throughout the rest of the journey to Goulburn. Two cars—Mr. Cox's Talbot and Mr. Holmes' Alldays—retired when reaching their destination; Mr. Walker had no less than thirteen punctures during the run. On this day also the horrible "V" culverts were more numerous than ever.

On the last day the weather turned dull, and the run developed into a race to Sydney, which was 129 miles distant. An early start was made from Goulburn. Mr. Hobbs covered the course with his Mercedes in a little over 4 hours, and he was followed by Mr. Stevens on his Darracq, both being received with hearty cheers by the great crowd assembled at the stopping-place to receive them. Although both cars arrived within the time limit, Mr. Hobbs was the winner in the Big Car Class, because Mr. Stevens had previously lost 10 marks, and this prevented him from making a tie. Mr. Dixon also would have received full marks had he not run out of petrol only 60 yards from the finish, and even then he could have run downhill and crossed the line, but for the fact that the spectators obstructed, so that he had to put on his brakes and stop the car. Mr. Arnott again suffered through his leaky radiator, and Mr. Rand was penalised through allowing his passengers to get out while ascending the Razorback Hill. Mr. Wittber lost seven minutes through the inlet-valve sticking, while Mr. Coleman also lost marks through the same cause. Mr. Day, with his 8-h.p. De Dion, was the leader among the single-cylinder car entries, while Messrs. Moffat, Grimwade, Fauvel, Wilkinson and Tarrant made a tie in class B, which was for cars of medium power. These latter, therefore, in order to decide the winner, had, on November 22nd, to run again from Sydney to Medlow Bath and back, a distance of 132 miles, during which the course rises 3,500 feet.

The cars taking part in the contest upon their arrival at Melbourne proceeded to the Agricultural Ground, where they received an ovation at a gymkhana organised in honour of the event by the A.C. of Australia.

The road taken by the cars to Medlow Bath was a severe test. Miles and miles of road had to be traversed where the surface consisted of loose deep sand and blue metal newly laid down. The hill-climbing about 40 miles out from Sydney included stretches of 1 in 6 and 1 in 5, whilst S-shaped curves were numerous. All got through except the Richard-Brasier, which had throughout the trial carried four passengers and kept a clean sheet. On crossing one of the fatal V-shaped culverts, near Penrith, at high speed, the right back spring broke, and Fauvel



Stevens' car that tried conclusions with the railway gates.

MELBOURNE-SYDNEY RELIABILITY TRIAL, November 14–18.

Photos by "Sydney Mail."

MELBOURNE-SYDNEY RELIABILITY TRIAL, November 14–18.—Along the whole route and including outlying country districts the occasion of the run was treated as a holiday, and schools and farm hands gathered along the roadside to see the cars go past. Our pictures above show some of these incidents. On the left is a scene of a "school out" on the Gundagai Road, in the centre one, watchers by the way at Kyambe are seen, and the right-hand picture is by the roadside at Tarcutta.

had no alternative but to retire. During the day Tarrant lost 3 points, but under the rules each competitor can lose 10 points altogether before being eliminated. The six survivors, therefore, were required once more to try their luck in determining the winner.

The next day's run was to Goulburn, 129 miles. All six made non-stop runs, Grimwade losing 3 points for adjustments. The following day, November 24th, the cars ran to Gundagai, 121 miles. Trivial matters resulted during the day in spoiling the absolute non-stop runs of all except Hobbs on his Mercedes, his mark sheet being still clear to date. On this day, too, a "V" culvert eliminated Moffat's 10-h.p. De Dion. In the next run, to Albury, Hobbs again came through without loss of a mark, and on the final run to Melbourne, on November 27th, the five remaining cars were still in perfect running order, and prepared apparently, like the brook, to "go on for ever." The position of the competitors at this last stage was as follows (full score 10 points):—

G. Hobbs (18-28-h.p. Mercedes), full points; S. H. Day (8-h.p. De Dion), 8 points; H. Tarrant (8-h.p.

Tarrant), 7 points; W. R. Grimwade (10-h.p. Argyll), 4 points; and W. B. Wilkinson (10-12-h.p. Talbot), 1 point, which would result in the Dunlop Trophy going to Hobbs' Mercedes car.

Few incidents characterised the runs of the motor cycle section. On the second day, the two James Brothers, who are thoroughly used to the roads, were the first favourites, especially as Mr. B. James won the first race last year. In the event, too, the preference was justified, for Mr. E. James, in the November contest, carried off the prize. On the fourth day, Mr. B. James had to retire because the vibration had loosened his frame. Up to that time, however, he had been riding well, and at very high speed. Mr. Jenkins and Mr. Gard both lost points on this section of the run, Mr. E. James being the only competitor in his class with a clean slate.

A competition up Razorback Hill was included in the last day's run of the cycle section. The hill was divided into three successive sections and 50 marks were awarded for each section climbed. In all, the hill is nearly one mile long, and provides gradients as steep as 1 in 6. Mr. James failed on the second portion, but climbed the first and third stages. Mr. Jenkins, on the other hand, climbed all but the last part. While racing along the road after surmounting this hill, Mr. James met with an accident which partly disabled his machine; he was able to finish the contest, however, by riding very carefully, and by so doing he secured first place.

THE 1906 THORNYCROFT MODELS.

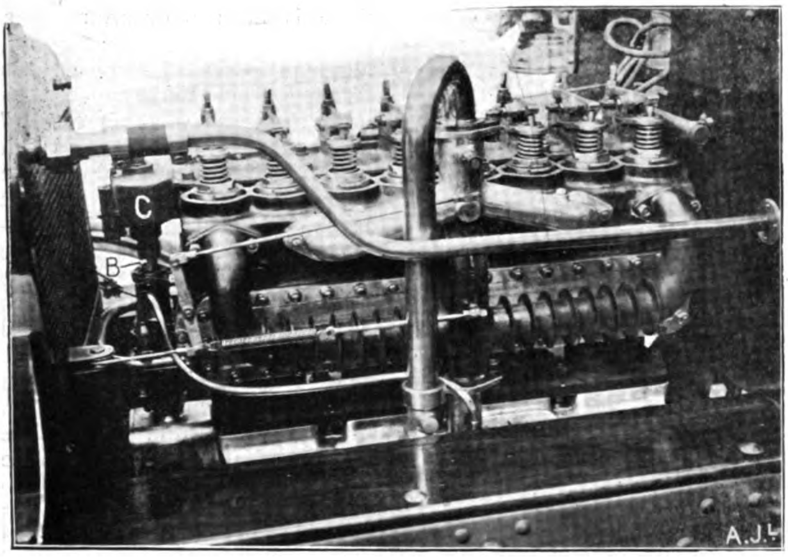

Fig. 1.—Side view of the 14-h.p. Thornycroft Engine.

Some weeks ago, in our issue of Nov. 18, 1905, we were able to give some leading particulars of the new models which this famous firm at Chiswick are constructing for the ensuing season. Supplementing that information, we now reproduce two photographs of the 14-h.p. Thornycroft engine which is being fitted to the smaller of the standard touring cars. This engine was first constructed to meet the requirements of the Thornycroft cars in the Tourist Trophy Race, and it differs in every respect from the 24-h.p. engine which is fitted to their earlier model.

All four cylinders are cast in one piece and all the valves are arranged in the cylinder-heads, where they are operated by rock-levers. Another interesting feature in the construction of this engine, and one too which renders it particularly accessible, is that the cam-shaft is arranged, alongside the cylinder-heads, in the casing, C, which is prominent in Fig. 2. Here it is driven by skew-gearing from a vertical shaft, B, which carries the centrifugal governor operating on the throttle. Mounted on the free end of the cam-shaft, and on the driver's side of the dash, is the high-tension distributor from which wires are led through a neat casing to their respective ignition plugs which project into the combustion-chamber through the cylinder walls. In Fig. 2 these plugs are clearly visible.

Bayonet socket-fittings render the valves very accessible, and indeed either valve with its seating can be bodily removed in a few seconds without dismantling anything but the rock-lever. Accessibility has always been striven after by the engineers of the Thornycroft firm, and it is undoubtedly largely owing to the extensive practical experience of Mr. Tom Thornycroft himself—who is one of the most ardent of present-day motorists—that so many interesting features have been adopted on their cars.

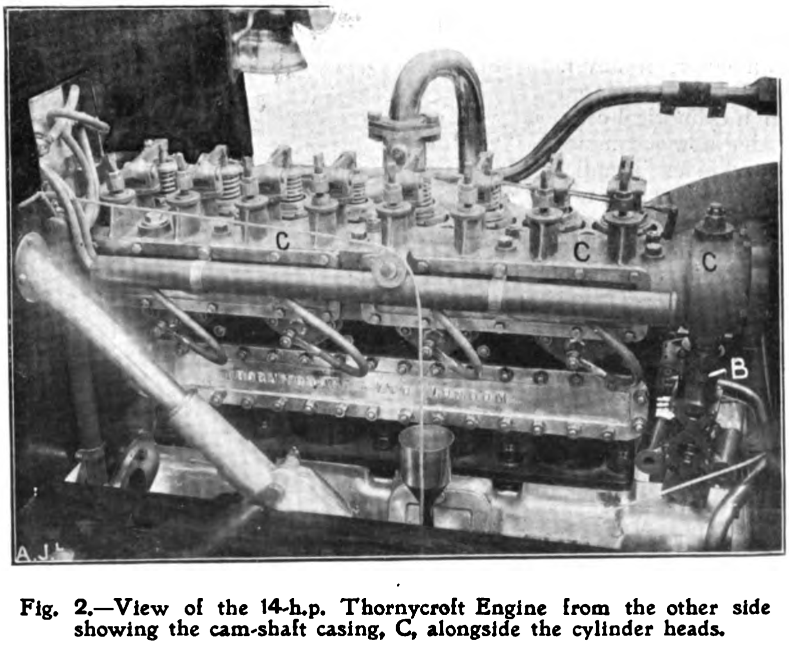

Fig. 2.—View of the 14-h.p. Thornycroft Engine from the other side showing the cam-shaft casing, C, alongside the cylinder heads.

HIGH-TENSION MAGNETO IGNITION—(*continued*).

THE EISEMANN HIGH-TENSION MAGNETO (1906 MODEL).*

EVEN though the few alterations which have been made in the new model of the Eisemann magneto are only modifications of detail construction, yet they are important, have been well thought out, and may be justly described as decided improvements.

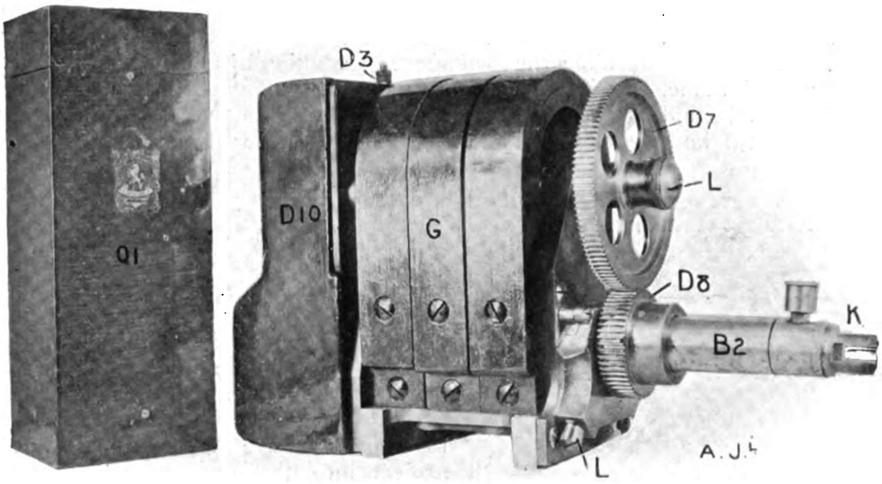

Fig. 1.—The Eisemann High-Tension Magneto (1906 Model).—View of the machine complete with its separate induction coil. The latter is now contained in a neat and substantial wooden case.

The general principle of this system, electrically, remains the same as before, while the magneto has, as is evident from Fig. 1, very much the same external appearance. The induction coil, which contains the condenser, however, is no longer enclosed in a cylindrical case, being now accommodated in a substantial wooden box.

The principal modifications have taken place in connection with the low-tension brush-gear, which has been redesigned on a stronger scale throughout. Originally, it will be remembered, the ends of the armature winding—which is still wound on a solid core—were connected to two similar slip-rings mounted on the armature spindle; and alongside these slip-rings was the contact-breaker cam. In the new model, however, the length of this end of the armature spindle has been considerably reduced by eliminating some of the members which it previously carried. Both slip-rings have disappeared, for instance, a brass knob, C^1, on the end of the spindle now constituting the live end of the primary winding, the contact-breaker cam, B^4, itself doing duty for the "earthed" connection. Even in the original machine the cam was mounted in contact with the "earthed" slip-ring, so there is no real departure from previous practice in this detail, although increased simplicity has resulted from the change. In order to ensure a thorough "earth" on to the bearing-plate, M^1, which carries the stationary side of the contact-breaker, C^3, a very neat brush, C^5—shaped like a fork—is arranged to press against the rear face of the cam. The simple method in which this device is arranged is very clearly indicated in Fig. 2.

The low-tension current is now collected by a spring contact-brush, C^4, mounted on the insulated bracket, C^6, which also carries the adjustment-screw, C^7, of the contact-breaker. The whole of this bracket can be

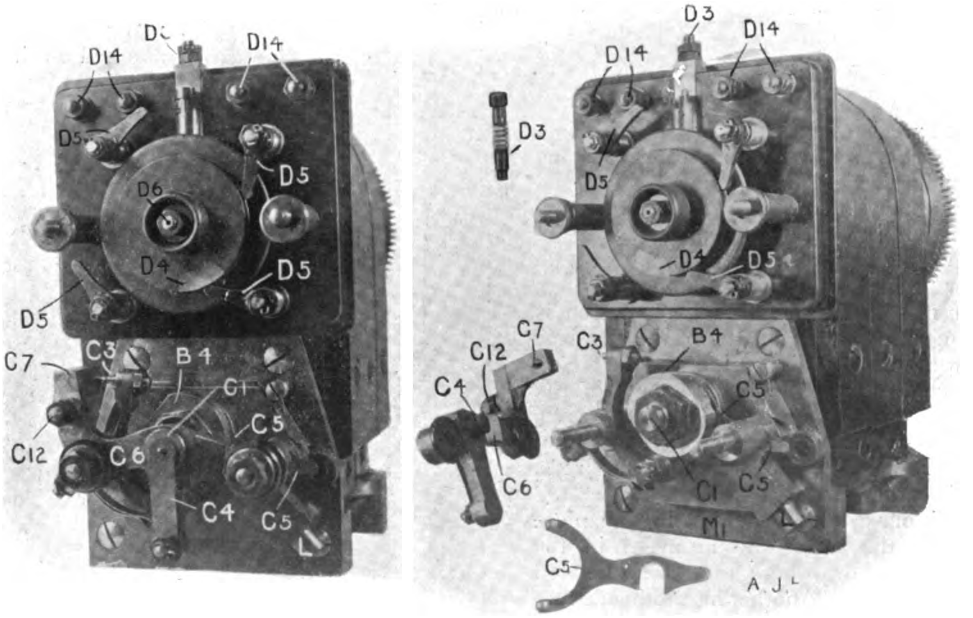

Fig. 2.—The Eisemann High-Tension Magneto (1906 Model). Views of the low-and high-tension gears showing the principal alterations in design. The low-tension gear has been entirely altered, but the high-tension gear has only been slightly modified.

---

* Our original description of this machine appeared in this Journal on October 8th, 1904, and is contained in the Automotor Library, Vol. I.

instantly removed by undoing two thumb-nuts, and in the right-hand view of Fig. 2 it is shown detached. There are no similarly radical departures in the high-tension gear, but one or two slight modifications have, nevertheless, been introduced. The distributing brushes, D^5, are now made so that they will remain away from contact with the revolving distributor, and the engine may thus be run on one or more cylinders only, for testing purposes, if required. A high-tension spark will, however, take place at the safety-spark-gap on the coil under such circumstances.

Another improvement in detail is the simple bayonet socket fitting for the feeder-brush, D^3, which can now be quite easily removed for renewal or inspection.

The external connections remain much the same as before, except that there is now only one terminal, C^{12}, which need be connected to the induction coil. The induction coil has four terminals, but two of these are permanently coupled, and a wire must be led from them to the frame, for they represent the "earthed" ends of the primary and secondary windings. The live low-tension terminal, which must be connected to C^{12}, is marked, on the coil-box, "B," while the live high-tension terminal, which is connected to D^3, is marked "H." It is, of course, necessary to "earth" the frame of the magneto in the usual manner.

Lubrication is, it will be noticed, no longer effected from oil-cups mounted on the top of the magneto. The distributor-spindle, D^6, is now lubricated by oil contained in the enlarged boss of the spur-wheel, D^7, while the armature-spindle is lubricated by wicks from oil reservoirs formed in the bearing-plates.

Our present illustrations are marked with the same reference letters as those previously employed, so that comparisons between the two models may be readily made.

* * * *

THE PARSONS COMPRESSION VALVE.

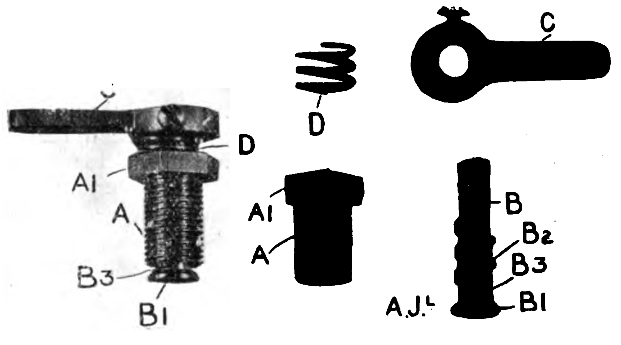

Fig. 1.—The Parsons Compression Valve. Views of the device complete, and also of its component parts separately. Escaping gases have to enter the hollow valve-spindle, B, through the ports, B^3, in order to reach the atmosphere.

VERY ingenious and very simple is the little valve which Mr. Parsons—who is already well known in connection with the heavy-oil engine bearing his name—has invented as an improvement upon compression cocks and drain cocks of the ordinary type. Our illustrations show its construction, and they also show how very easily it may be dismantled, should this be necessary. The device consists of four pieces only, a screw-fitting, A, valve-spindle, B, lever, C, and spring, D. On the valve-spindle, B, is the thread, B^2, which engages with a corresponding thread inside the sleeve, A. Instead of meshing closely, however, they are allowed a considerable amount of back-lash, and in this fact lies the whole point of the valve. An ordinary conical valve-head, B^1, forms the lower end of the stem, B, and just above this are four little ports, B^3, communicating with the hollow interior—which is open at the other end, to the atmosphere. Anything escaping or entering through the valve can, therefore, pass through the hollow valve-spindle.

Normally the valve is held against its seat by the spring, D, and it is capable of acting within the limits of the back-lash, as a simple automatic non-return valve. As such, it is particularly useful when injecting petrol or paraffin, because it prevents the liquid being blown out again during the up-strokes of the piston. When required it may be opened instantly by direct pressure, but on the other hand it may be set so that direct pressure has no effect. By means of the lever, C, the valve may be opened positively and be left open indefinitely, for the pitch of the thread is such as to prevent any pressure behind the valve from closing it automatically under these conditions.

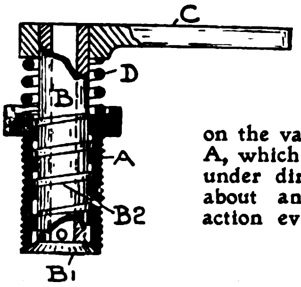

Fig. 2.—The Parsons Compression Valve. Sectional drawing showing the clearance between the threads on the valve-spindle, B, and the sleeve, A, which permits the valve to open under direct pressure and also brings about an automatic "grinding-in" action every time the valve is opened and closed.

More important still, however, is the facility with which the valve may be ground in to prevent it from leaking at any time, for the back-lash between the threads permits a partial rotation of the valve while it is still on its seat. This action, it will be noticed, can take place when the valve is in use if the lever, C, is correctly adjusted, and there is consequently a tendency for the valve to automatically maintain its seat in good condition.

* * * *

London Traffic.

AT the Monthly Dinner of the London Chamber of Commerce, taking place on February 21st, the subject for discussion will be "London Traffic." Mr. Felix Schuster, chairman of the Council and a member of the recent Royal Commission on London Traffic, will preside, and a number of well-known experts on the question have been invited to attend and speak on this subject, which is of so much interest to both the motor trade and the general public.

THE AUTO-MIXTE PETROL-ELECTRIC CAR.

Few ideas have been so persistently followed as that of combining the internal combustion engine with a dynamo, on a motor car, for the purpose of eliminating any mechanical change-speed-gear. Extremely limited success has, however, attended the numerous practical efforts in this direction, and naturally each succeeding year removes something of the urgency for such a system, because the enormous improvements which have taken place in the construction of standard petrol cars, and especially in the engines, have tended towards that flexibility of control which is the real aim of all petrol-electric combinations. Primarily, the chief stumbling-block to any such arrangement is that of weight, for the dynamo and the motors are each as heavy as the petrol engine, while the accumulators—when used—are, as everyone knows, not only heavy and bulky, but apt to give trouble as well. When accumulators are not used, a portion of the weight is saved, but one of the most important advantages—the storage of energy—is lost also, and the system is then merely equivalent to a variable gear.

Very diverse, however, have been the numerous systems adopted; some, like the Krieger, merely use the electricity as a medium for the transmission of power to the driving motors; others, like the Fischer, supplement this by a battery of accumulators, which affords a source of reserve power and enables the engine—which may be built on the small side—to be kept running always at an approximately constant speed and load. In other cases, like that of the Germain, the dynamo and motor form a compound unit which provides a gradually variable change-speed-gear; whilst in the Auto-Mixte system—now exhibited at the Paris Salon—it is the dynamo itself which is occasionally used as a motor (in conjunction with accumulators) when the engine needs temporary assistance.

This dynamo, A, is mounted immediately behind the engine, and just behind the dynamo is the main clutch, C. The armature is thus caused to revolve so long as the engine is running. A propeller-shaft transmits the power to

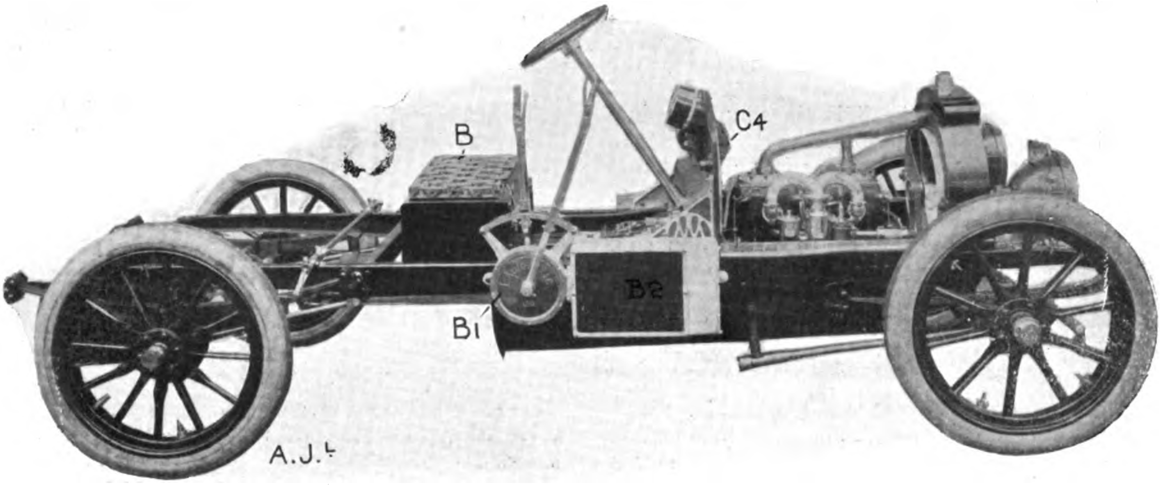

Fig. 1.—The Auto-Mixte Petrol-Electric Car. Side view of the chassis showing the position of the accumulators, B, and of the controller, B^2, which is operated by a side lever through a spur-wheel enclosed in the case, B^1.

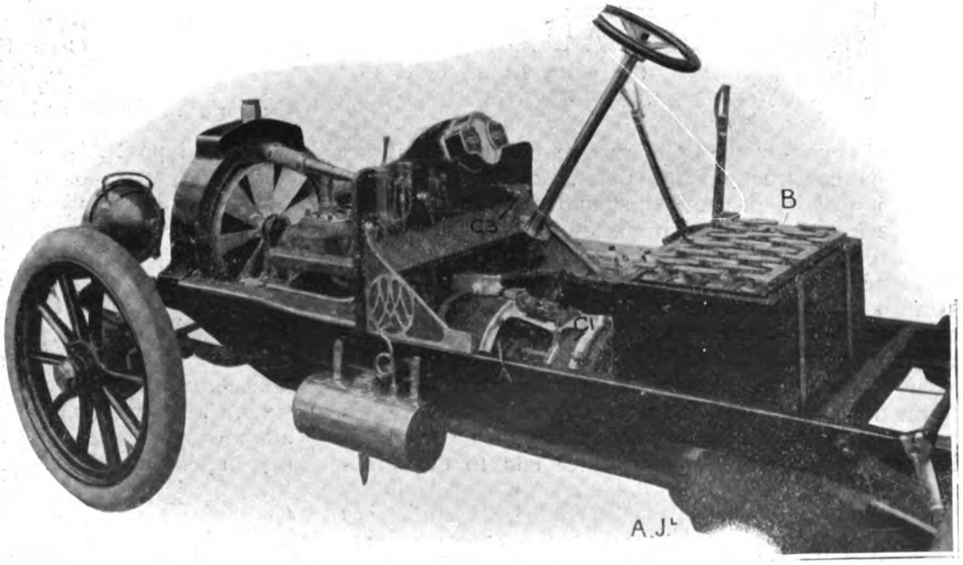

Fig. 2.—The Auto-Mixte Petrol-Electric Car. View showing the dynamo, A, which is mounted about the main-shaft and does duty for a change-speed-gear. It is always in action while the engine is running. At times it is used to charge the accumulators, but when necessary it becomes a motor, and so allows the accumulators to help the engine.

the live-rear-axle and, there being no mechanical change-speed-gear, the drive is always direct. Under the driver's seat is a battery of accumulators, B, by means of which the dynamo itself can be used as a motor whenever it is desired to increase the speed of the car or to help the engine in driving it up-hill. It also forms the only means of reversing. When not in use, the battery is charged by the dynamo if the conditions are favourable and the engine is not already fully occupied in its task of driving the car. On the Auto-Mixte chassis, the battery consists of 28 Tudor cells, these weigh 375 pounds, so that altogether the chassis weighs 2,775 pounds in running order. All the cells are coupled up in series.

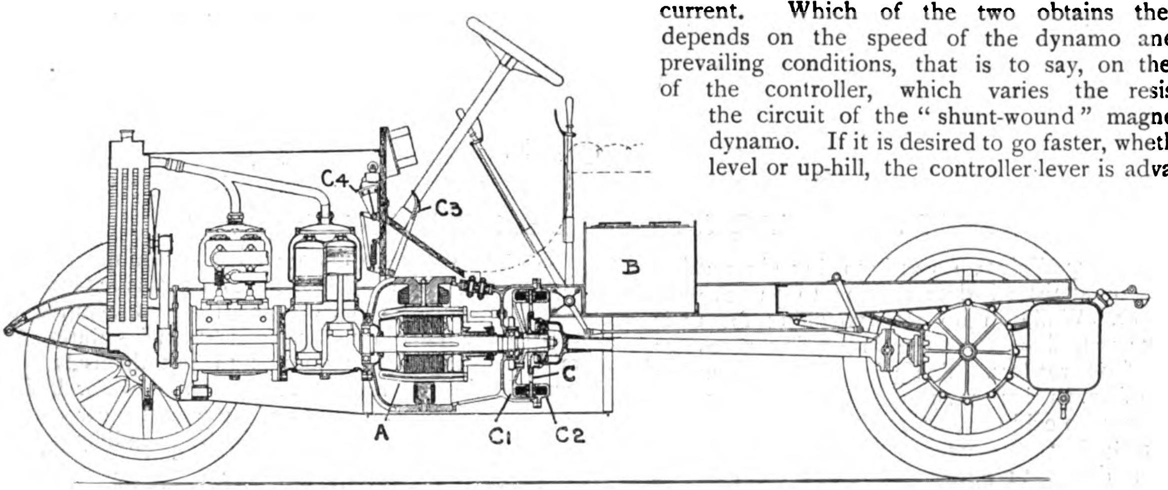

Fig. 3.—The Auto-Mixte Petrol-Electric Car. Sectional elevation showing the arrangement of the dynamo on the main driving-shaft, and also of the magnetic clutch, C, which can be used, when required, as a brake.

At the driver's right hand is a lever which operates the controller, B^2, mounted on the side of the frame, and in front, on the dash, is a volt and ampere meter which indicates what conditions are prevailing by showing whether the batteries are discharging, being charged, or are in a state of electrical rest. It will be understood that the battery is all the time trying to assist the engine by discharging its current through the dynamo—thus converting it into a motor, and that the dynamo is equally in readiness to charge the accumulators by reversing the current. Which of the two obtains the mastery depends on the speed of the dynamo and on the prevailing conditions, that is to say, on the position of the controller, which varies the resistance in the circuit of the "shunt-wound" magnets of the dynamo. If it is desired to go faster, whether on the level or up-hill, the controller lever is advanced forward, and this, by weakening the voltage of the dynamo, renders the battery more in a position to drive it as a motor. On the engine is a magnetic governor, D, which acts directly on the throttle-valve, and in conjunction with the controller is an electro-magnetic device which times the ignition. Ordinary low-tension igniters are employed, but the position of the iron core in the intensity coil of the circuit is made adjustable, and is connected to the controller lever. Altering its position varies the "fatness" of the spark, and the relative igniting powers of the "fat" and the "lean" sparks are considered sufficient to give the necessary advance or retardation.

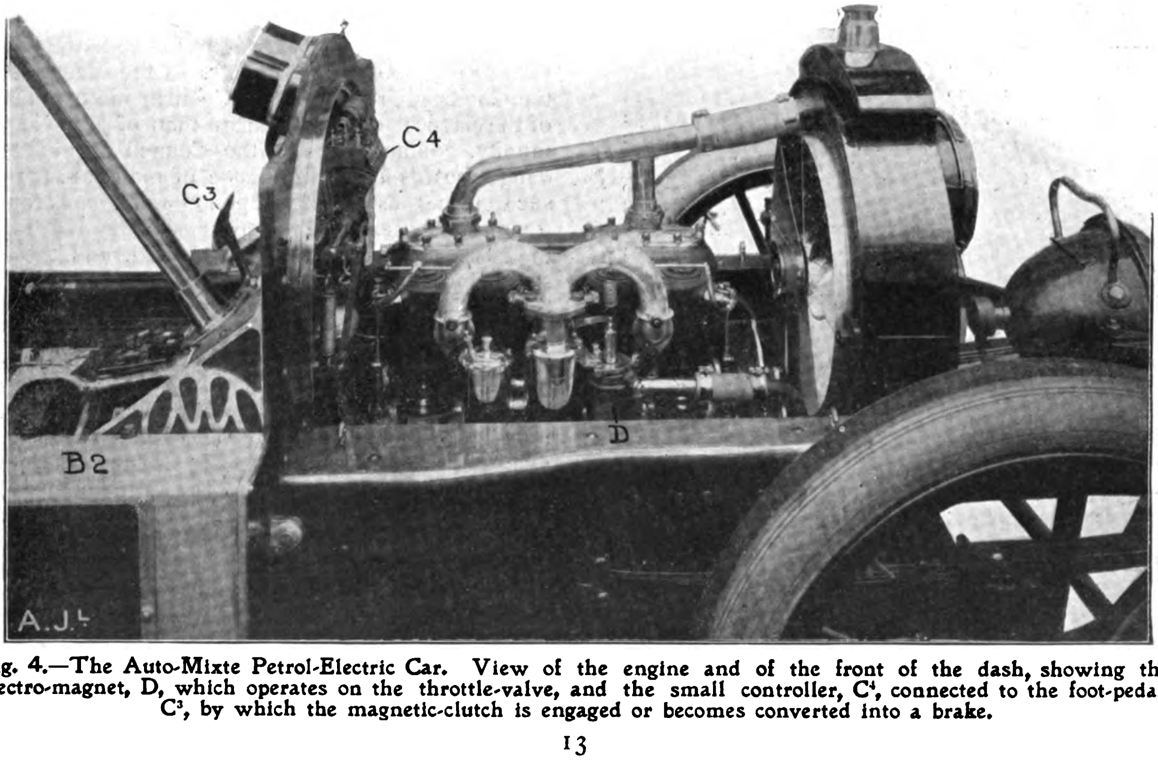

Fig. 4.—The Auto-Mixte Petrol-Electric Car. View of the engine and of the front of the dash, showing the electro-magnet, D, which operates on the throttle-valve, and the small controller, C^4, connected to the foot-pedal, C^3, by which the magnetic-clutch is engaged or becomes converted into a brake.

For controlling the electro-magnetic clutch, a pedal, C^3, is provided, which operates a small controller, C^4, mounted in front of the dash. The clutch is of the single disc type, and its arrangement is shown in Fig. 3. Mounted on the propeller-shaft is the flat disc, C, and on the engine shaft is an annular electro-magnet, C^1. When the pedal is released, current flows in the coil of wire on C^1, and the whole casting becomes a magnet, which then attracts the disc, C, and clutches the two shafts together. As on a petrol car, the clutch pedal must be released gradually—in order that the resistances in the circuit may be used with their proper effect. When pressed right forward the same pedal applies a brake, or, rather, converts the clutch into a brake, for behind the clutch, C, is another electro-magnet, C^2, similar in every respect to C^1, except that it is stationary. When energised, therefore, it attracts the disc, C, and thus retards the propeller-shaft.

* * *

STATISTICS OF THE 1905 SALON.

Our contemporary, *L'Auto*, has again made an interesting compilation of statistical data relating to the present French Show. While in no way vouching for their accuracy, we reproduce the more interesting notes for the benefit of our readers. These figures are, we understand, taken from particulars supplied by fifty-five French manufacturers who exhibited at the Salon 326 vehicles, including 148 complete cars and 178 chassis. These represent 150 different types.

The following list shows the percentage construction of cars of different powers for last year and this :—

Type. H.-P.	1904. Per cent.	1905. Per cent.	Average price (1905). Francs.
6	3	2	—
8–9	17	6	4,750
10–12	12	15	7,200
14–16	23	19	10,300
20	16	13	—
24–30	20	27	15,200
Above 35	8	18	—

It is estimated that the average price per horse-power has undergone a reduction of about eighty-five francs this year.

Various points of constructional detail are compared in the following table :—

Cars and the General Election.

Any car owners who are sufficiently public spirited, self-sacrificing and politically enthusiastic to be willing to provide cars for the conveyance of voters to the polls in various constituencies during the coming election, are requested to put themselves in communication with the secretary of the Motor Union, who is organising the forces of automobile car owners in support of those Parliamentary candidates who are in favour of automobile progress. We believe it is an unwritten law of the Union in such cases that persons agreeing to lend cars will only be asked to furnish them for service at elections in their near neighbourhood, as, of course, it is not reasonable to expect a car owner to send his vehicle too far afield. At the same time there may be cases in which enthusiastic car owners will be willing to send their cars to the more distant elections which in most cases take place later. If they are sufficiently self-sacrificing for this, it will, perhaps, be as well that they should explain it to the secretary of the Motor Union.

Urban District Councils and their Work.

Local authorities so frequently regard automobilists from such a lofty attitude—*de haut en bas*, as the French say—and assume such an attitude of infallibility that few automobilists will be able to restrain a smile of amusement when they find a body of this kind "putting its foot in it" in such a way as even to excite the hilarity of their own supporters. We refer to the recent action of the Chertsey Urban District Council, more reminiscent of the classical city of Gotham than of a modern community. Some time ago the Council decided to erect danger boards for the guidance of motorists, to indicate such places as in their opinion were dangerous, and where but moderate speeds should be indulged in. Triangular devices were adopted, and these were set up at the crossing at Bell Corner and in Guildford Street. They had not been erected and duly admired by the local Bumbles very long when Mr. J. F. Ochs, of St. Anne's Hill, a well-known member of the Automobile Club, pointed out that they were put up *on the wrong side of the road*, the result, of course, being that no passing motorist would be likely to notice them. One would have thought that the Council of Gotham—we mean Chertsey—on having the mistake pointed out would at once have rectified it. Not a bit of it ! They replied to Mr. Ochs that "in the opinion of the Council the danger signals have been placed in a most advantageous position." Any people less infallible than a District Council would have admitted their mistake and rectified it. And these are the sort of people who wish to have absolute control of the speed of motor cars in their districts !

THE "AMAC" CONTACT-MAKER.

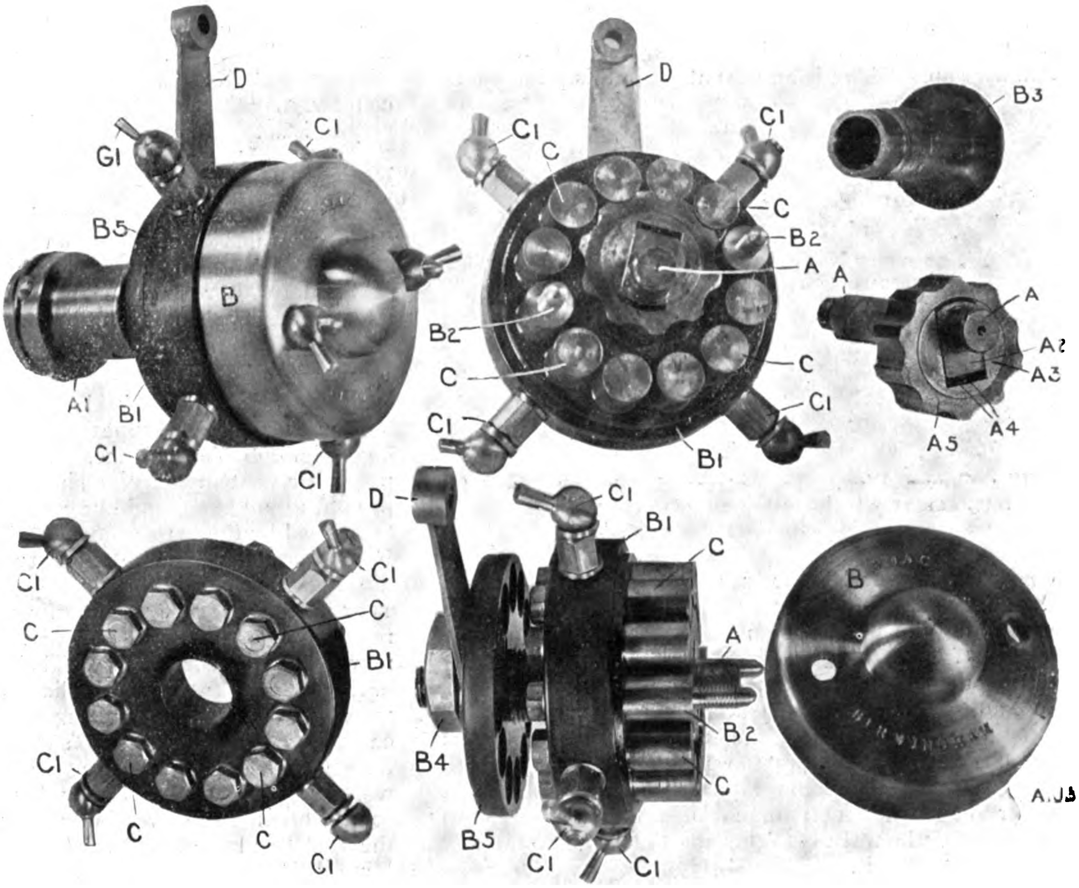
QUITE unlike the majority of "commutators" used with petrol engines is that made by the Aston Motor Accessories Company, of which we give a group of illustrations, reproduced from photographs. It is the invention of Mr. F. H. de Veulle, and is of very ingenious but simple construction, that enables all the moving parts to run in grease, while a really good electrical contact is ensured by the rubbing action of the moving part over the surface of the stationary contact-pillars.

One illustration shows the contact-maker complete with its detachable cover in place, while to the right of this view is another with the cover removed, and on the extreme right is the revolving shaft carrying its contact - making wheel, with its bearing sleeve just above it. Beneath these views are others, showing the back of the main portion of the apparatus, the entire contact-breaker partly dismantled, and the metal cover alone.

Referring to these, it will be seen that the shaft, A—which can be connected up to the engine by the coupling, A^1—is formed solid with a square carrier, A^2, and that it projects sufficiently far forward to take a bearing inside the cover, B. Engaging with the carrier-block, A^2, is a kind of eccentric-sheave, A^3, which slides over it, and it is at all times pressed outward by two small helical springs, A^4. Outside, and free to turn on the eccentric-sheave, is the contact-making wheel, A^5, which thus forms an eccentric-strap. The teeth that are formed around the periphery of the wheel, A^5, are ten in number, and their curvature is such that they fit closely up against any of the twelve brass pillars that are fixed to the ebonite plate, B^1. Owing to the action of the springs, A^4, the wheel, A^5, is always kept in contact with one or two of the brass pillars, and the effect of revolving the shaft, A, is to make the wheel, A^5, rub round each pillar in turn whilst it is passing on from the previous pillar to the succeeding pillar. In this way the grease is squeezed out from between the rubbing faces, and a good electrical contact is ensured.

Four of the brass pillars (those marked C) are provided with outwardly projecting terminals, that receive the low-tension wires for the four cylinders, but the remaining pillars are merely insulated guide-blocks for steering the toothed-wheel, A^5, in the required direction. Two of the latter, B^2, are, however, utilised for holding the cover, B, in place, these being slightly longer than the others.

The ebonite plate, B^1, has a brass bush, B^3, that forms a long bearing for the shaft, A, and this bush is held firmly in place by a pinned flange at one end and by the nut, B^4, near the other end. Behind the plate, B^1, is an ebonite cover-plate, B^5, with holes drilled in it to correspond with the nuts at the back of the plate, B^1, and this cover-plate is also held up against the main plate, B^1, by the large nut, B^4. Two purposes are served by the cover-plate, B^5, for not only does it protect the nuts inside it, but it enables the timing-lever, D, to be fixed at any convenient angle. This timing-lever is used for rocking the commutator about the shaft, A, in the usual way, and is for this purpose pinned to the cover-plate, B^5. By slackening back the nut, B^4, the plate, B^5 (with the lever, D), can be drawn clear of the pillar-nuts, and can



The "Amac" Contact-breaker, for a four-cylinder petrol engine. Views showing it both complete and partly dismantled.

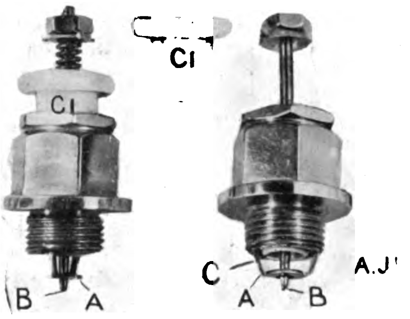
then be replaced at the required angle—twelve alternative positions being available.

It will, of course, be understood that the effect of the apparatus is to alternately "earth" each of the insulated terminals, C^1, thus completing the circuit to each of four induction-coils in regular sequence. Similar contact-makers are also constructed for use with any engine having one, two, or six cylinders, and we learn that the manufacturers are also about to combine a high-tension distributor with this type of "commutator."

⊛ ⊛ ⊛ ⊛

THE CROWN IGNITION PLUG.

So many different forms of ignition plugs find their way on to the market that it must now be quite difficult for inventors to discover a new design. One of the latest to come before our notice is called the "Crown," and has been sent to us by the United Motor Industries, Limited, who keep an enormous stock of plugs of every description. This particular model is principally peculiar for the form of its sparking points, which provide an annular gap. There is an advantage in this principle of construction, especially for use with magnetos, because it affords several alternate paths for the spark, thus preserving them from being burnt away so quickly. The actual construction of the plug is clearly shown by our photograph; the live terminal is simply a straight rod, and surrounding its extremity is a small ring, B. Another feature is that the upper porcelain, C^1, is detachable for cleaning purposes. In accordance with modern practice the lower porcelain, C, is tubular, in order to allow a certain amount of scavenging action to take place, which tends to prevent the formation of any permanent deposit.



The Crown Plug. Two views showing its special points, among which are the annular sparking gap and the detachable porcelain, C^1.

⊛ ⊛ ⊛ ⊛

Extraordinary Attempt at Municipal Extortion.

A VERY important triumph for the Western Road Carrying Company, the Motor Van and Wagon Users' Association, and the Society of Motor Manufacturers and Traders, is provided by the decision in the recent case, to which we have already referred, in which a local authority, viz., the Keynsham Rural District Council, sought to obtain damages for extraordinary road traffic against the Western Road Carrying Company for injury said to have been caused by their motor lurries. The action, which was taken under the Locomotives on Highways Amendment Act of 1878, resulted in a complete victory for the defendants, the Keynsham Council, who had been ordered by the Court to make a full disclosure of their books, failing to substantiate the damage for which they claimed. A summons was then taken out on behalf of the defendant company for the action to be dismissed with costs, and so the proceedings came to an end. There is no doubt that this attempt by the Keynsham Council was being looked upon by other similar bodies very largely as a test case, and we can hardly entertain any doubt that had the prosecution been successful it would have been followed by a regular crop of similar incidents. The Motor Van and Wagon Users' Association, as well as the defendant company and their legal advisers, and all users of heavy vehicles throughout the country, may therefore be heartily congratulated on this very satisfactory result.

By Way of Example.

THE miscreants who erected a pile of stones in the road over which Queen Margherita travelled last August through Italy, which caused a serious accident to Her Majesty's car, have been sentenced to various terms of imprisonment varying from 20 to 11 weeks.

Auto-Highwayism.

WE were always afraid that this was what would happen ever since the appearance of that fascinating but highly improbable romance, "The Motor Pirate," in the pages of a contemporary. These tales of crime always prompt to imitation, and our contemporary has evidently been read by the masses not only in this country but in France as well. We referred last week, in summarising the tendencies displayed by the automobile world in 1905, to the increasing popularity of the car, due to the recognition of its useful qualities. This recognition is now likely to be shared in social circles more regularly at daggers drawn with the police, even than ordinary motorists. Two enterprising youths of the French capital, a few days ago, succeeded in stealing a high-powered car belonging to a wealthy American resident, and with this they have been touring the roads, holding up everybody they met, and bidding them "Stand and deliver" in the good old time-honoured highwayman style. So successful were they that by the time they reached Tours the unwilling offerings of their victims amounted to as much as £300, and on one occasion they even carried off a farmer and his pig. They requisitioned provisions and petrol at their pistol's point, and goodness knows how long they would have carried on the exploiting of France had they not come a mucker into a tree, with the result that their stolen car was rendered incapable of serving them further, and once they took to the road and the railway they were easily recognised and arrested. The motor car has brought back many of the old conditions of travel of the eighteenth century. If it is to reproduce in another form the old-fashioned highwayman, there will no longer be an excuse for maintaining that it has not added to the picturesqueness of modern life, as, if the example of the two French chevalier d'industrie is at all generally followed, a good many people will be disposed to twit Lord Montagu on the blood-curdling romance that first appeared in his paper.

THE "WHITE FLYER."—THE MOTOR-DRIVEN AEROPLANE OF THE BROTHERS WRIGHT.

ANY lingering doubts that may still be entertained in regard to the reality of the Wright Brothers' performances are now likely to yield to the circumstantial report which the enterprise of our contemporary, *L'Auto*, has enabled it to place before its readers. The French journal in question, as soon as it was convinced that the rumours of successful motor-driven aeroplane flight were more than mere rumours, at once dispatched a representative (M. Coquelle) to Dayton, Ohio, to investigate matters on the spot, and this investigator has furnished to his paper a detailed account, the perusal of which goes far towards removing any doubt as to the substantial correctness of all the claims that have been made on behalf of the two brilliant experimenters, and fully establishes the general truth of the statements previously published on the subject by Captain Ferber.

This is not, however, the only confirmation of the statements we were enabled to make last week, which has since come to hand. A further report has been furnished by Mr. Weaver to M. Frank Lahm, of the French Aero Club. Mr. Weaver, it will be remembered, was some time ago commissioned to ascertain what truth there was in the various rumours, and, in accordance with instructions, he sent to M. Lahm a telegram (which we reproduced at the time) stating that the claims made on behalf of the Brothers Wright were fully substantiated. Mr. Weaver's report, dispatched by post at about the same time as his telegram, is now to hand, and fully confirms the report rendered by M. Coquelle.

The whole subject is of extreme interest, and it will ultimately, no doubt, be regarded as epoch-marking in the highest degree. We are dealing with the first reports of absolutely the first successful attempts to accomplish mechanical flight, and it is not astonishing, therefore, that a large mass of material has already found its way into the Press. The discovery of exactly what the Wright Brothers have accomplished, and its publication to the world under the circumstances, must certainly be regarded as a credit to the enterprise of French journalism.

For the benefit of our readers we propose to sum up the available data on this absorbing topic under the following headings:—

1. What the Wright Brothers have actually accomplished.
2. The evidence on which the statements are based.
3. The means by which they have effected it.
4. The reasons for their reticence.

1. What the Wright Brothers have actually accomplished.

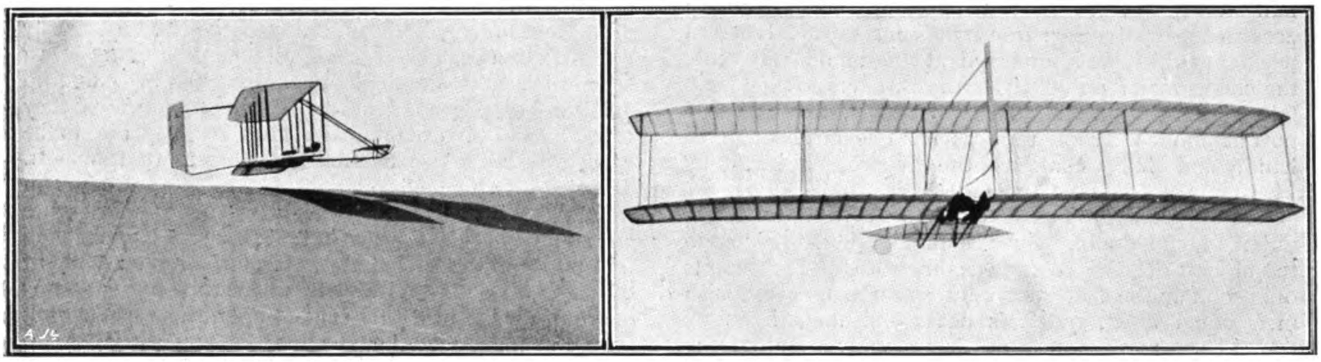
The record of actual accomplishment is shown by all the further evidence which has now come to light, to be almost exactly what it was declared to be in the letter to Captain Ferber, mentioned in our number of Dec. 9th, that is to say, they have made a large number of different flights averaging a speed of a kilometre to the minute (or not much under 40 miles an hour), and on one occasion actually covered a distance of 24¼ miles before touching ground.

These flights and experiments were carried out in a large meadow in the neighbourhood of Dayton, where on the ground of a friendly farmer the two enthusiastic aeronauts, who in Dayton and private life are bicycle manufacturers, had erected a shed for the accommodation of their flying machine. Round this patch of prairie, which was a rough quadrangle of about 1½ kiloms. in extent, flights were conducted and various manœuvres and experiments at different heights from the ground carried out. The maximum height attained was about 80 feet, and the "White Flyer" (the name the Wrights have bestowed on their machine) careered round and round the field till the various distances which we have previously recorded were accomplished. The actual distances over the ground mentioned are only approximate, for the method of calculating distance was by means of a small anemometer rigged up on the flying machine, the anemometer of course only actually recording the distances travelled through the air. Experiment, however, proved that the records substantially agreed in most cases with the distance travelled over the ground, as the flights were conducted round and round approximately the same course.

As in their gliding experiments, the recent flights of the Wright Brothers with their motor-driven aeroplane, have been extraordinarily conspicuous for a total absence of accident, due, no doubt, very largely to the remarkable mixture of bravery and caution which we have previously pointed out as characteristic of all their proceedings. In fact, in nearly all the flights they succeeded in ending up and coming to ground near the shed from which they started, and only exceptionally had the aeroplane to be carried back any distance by other means of transport. The nearest approach to an accident was on one occasion when Mr. Wilbur Wright swooped at slightly too acute an angle towards the ground, and instead of righting himself again descended abruptly amid a numerous herd of pigs, whose astonishment when this portent—this enormous white bird—descended upon them like a bolt from the blue, may be imagined. The witnesses, to whose evidence we shall next refer, and who were present at many of the actual flights executed, were most impressed, at any rate during the later flights, with the amazing manageability of the machine. It moved up and down, executed turns and figures exactly as the aeronaut managing it desired, and on one occasion performed an almost exact figure of eight inside a square of some 400 metres. Wilbur and Orville Wright, as in their gliding experiments in North Carolina, managed, rode, or flew (whichever expression is preferred), the machine alternately. The last splendid flight on the 5th of October, of 24¼ miles, was really only brought to a conclusion by the exhaustion of the petrol supply for their motor.

2. The Evidence on which the Statements are based.

The campaign of experiment for the year was brought somewhat abruptly to a conclusion with the last great flight of October 5th, owing to the fact that one of their friends who had been privileged to witness previous experiments, although "straitly charged not to do so," had been talking rather big about the wonderful things that he had seen. The consequence was that a large detachment of Daytonians assembled on the ground, to the great annoyance of the aeronauts, who, from reasons to which we shall refer later, were still anxious to avoid anything in the nature of publicity. They accordingly decided to bring their experiments for this year to a conclusion somewhat sooner than they had intended, and dismantled their aeroplane with a view to thoroughly overhauling it and introducing various improvements. M. Coquelle consequently was unable to see anything more than the parts of the machine which has established these wonderful records, and had to derive what consolation he might from inspecting the shed from which it had repeatedly issued to its triumphs. But he was able to collect very thorough evidence while in the district from a number of trustworthy people who had witnessed the flights. The first of these to whom he betook himself was a resident in the neighbourhood of the "scene of the exploits," who discharges the functions of a Justice of the Peace, Mr. M. D. Beard. He bore witness to having seen the Wright aeroplane manœuvring above his property with what he described as extraordinary ease, and he felt convinced that the intrepid manipulator was not in the slightest danger. Practically the same statements were made by Mr. Beard to Mr. Weaver, who, as we have above explained, investigated the question independently, and to his name may be added that of Mr. W. C. Foust, of Dayton. Altogether, there are some seven independent witnesses whose names have been collected, and who are prepared to vouch for the correctness of the reports furnished.



The Brothers Wright's Aeroplane with which they successfully accomplished glides of nearly 300 yards in the Devil Kill Hills in 1903.

3. The Means by which they have Effected It.

No photographs or authentic reproductions or representations of the actual motor-driven aeroplane with which these flights were accomplished have, as far as we are aware, been made public, though a sketch has been published which must be regarded as mainly imaginary or ideal, as the machine was admittedly taken to pieces at the time of M. Coquelle's visit. By drawing attention, however, to the differences between the motor-driven machine and the aeroplane with which the long glides of 1902 were effected, a general idea of the structure of the machine can easily be formed. For this purpose we reproduce the illustration of that machine which we gave on Feb. 6, 1904. It will be remembered that in general outline it resembled the aeroplane of Mr. Chanute, without the polyhedral tail. Instead, it was provided with a vertical tail at the rear for steering sideways and keeping the machine "on a level keel," and a small plane mounted in front, the angle of which was controlled by the operator by means of cords. In gliding from a height, the way this machine was manipulated was as follows:—If the downward tendency was too great, the front movable plane was slightly elevated, causing the whole machine to rise against the wind. If the wind were raising it too much, the movable plane was accordingly depressed, tending to cause the front of the machine to dip deeper into the air and swoop towards the ground. If what Mr. Chanute terms "a whirling billow of air" tipped up one or the other side of the machine, this was corrected for by movements of the vertical rudder, causing the aeroplane to swing round like a bird executing a curve, and so bring the depressed side up level again.

The motor-driven aeroplane with which the successful flights of the present year have been conducted closely resembles the gliding machine which we now reproduce, excepting of course that it has a motor and propellers attached. There are, however, other differences. Instead of the single guiding or controlling movable plane in front, there are two of them mounted, one above the other, and somewhat higher in position. Similarly the tail has been duplicated, there being now two tails, a couple of yards apart, behind each of the propellers. The general dimensions of the aeroplane are slightly greater than the gliding machine, being now 40 ft. from tip to tip, the large planes themselves being 6 ft. wide, and separated from one another by a space of 6 ft. The number of vertical struts also has been increased. They are stayed and reinforced by diagonal piano wires, and the whole apparatus made very strong and rigid. There has been no attempt to sacrifice everything for lightness. The motor is mounted at the extreme rear of the lower aeroplane. It is a 4-cylinder machine, constructed by the Wright Brothers themselves, and presenting much similarity with a 4-cylinder Pope-Toledo motor of the same power, viz., 24-h.p. The two propellers are mounted about half-way between the upper and lower planes close to the rear struts, being stayed to the corresponding front struts, and are chain-driven from the motor, revolving at a very high rate of speed. The struts of the whole machine are formed of birchwood with light canvas to form the gliding surface. As in the guiding machine the aeronaut lies prone, his chest resting on a cushion, and his head just below the two movable guiding planes, his feet not being very far in front of the motor. To produce proper balancing, a dead weight of some 50 lbs. is attached to the front part of the aeroplane to assist in counterbalancing the motor, which weighs some 250 lbs. In a recent statement, signed by both the Brothers Wright, they observe that no special pains have been taken to render their machine exceptionally light. The motor is no lighter than usual, and the whole thing is very solidly and firmly made. As at quite ordinary speeds they find that it is possible to lift and maintain in the air 66 lbs. per h.p. and very much more at higher speeds, this is quite credible and shows pretty clearly that as far as mere engine power is concerned, flying has been possible for many years past. It is skilled manipulation of the machinery which has been wanting.

It will be obvious from what we have said above, and what we have on previous occasions put before our readers, that the greater part of the conquest of the air, which the Wright Brothers have effected, was accomplished when they learned successfully to perform their record glides with the machine which we formerly illustrated and now again reproduce. They made no secret at the time, and authorities on the subject like Mr. Chanute have been always fully convinced, that their success in gliding was due partially to the horizontal position of the aeronaut—a position, by the way, which it requires at first, at any rate, considerable pluck to assume—and the arrangement of the subsidiary planes, particularly the movable and controlling front plane. When a machine of this type had proved to be repeatedly capable of performing glides up to nearly 300 yds. in length against a moderate wind by being simply started from the top of a hill, it was obvious that with motive power sufficient to represent the wind, and but a little extra power sufficient to represent the effect of gravitation, extended flight would be possible, and that the manipulation and management of the machine would not be greatly different, and this is what practice has proved to be the case. The really important elements of their invention therefore, consist of these three things, and we put them in order of increasing importance—the horizontal position of the aeronaut, the vertical tail or tails, and the forward approximately horizontal controlling plane, or planes. There may be other things which we do not know of as yet, but it is obviously those elements which have, so far as can be judged, made the difference between the extraordinary success which the Wrights have accomplished, and the ignominious failures which have been the record of practically everybody else.

The absolute control and manœuvrability of the machine, together with the degree of safety attained, are well illustrated by the fact that on one occasion when the engine stopped, the aeroplane glided slowly and quietly to the ground without occasioning the slightest trouble or the slightest injury. In fact, their regular method of coming to earth is to stop the engine some little time before they intend alighting and then to glide down.

A few words should be added regarding the method of starting adopted. The two guides or supports, which are clearly shown underneath the old aeroplane, and which are preserved in the motor-driven machine, are mounted on the top of a triangular little trolley, which runs on wheels on an ordinary rail. The aeroplane is mounted on this and held steady while the aeronaut assumes his recumbent position. The motor is started, the propellers begin to revolve, and the aeroplane runs down the rail on its carriage, being held straight by an assistant operator for the first few yards, and then as it gathers speed it rises in the air (leaving its carriage behind it) "as easily and gracefully," said one of the eye-witnesses, "as a butterfly."

4. The Reasons of their Reticence.

There remains to be considered the extraordinary reticence of the Wrights in regard to their marvellous experiments—a reticence so remarkable that it has surrounded the whole of their proceedings (since in 1903 they packed up their first motor-driven aeroplane and "went home convinced that the day of flying machines had come") with an atmosphere of distinctly piquant — not to say irritating — mystery. It is so opposed to the usual American methods, though it must be admitted that it is not opposed to the previous record of the Wright Brothers themselves. The public generally knew absolutely nothing about their experiments on North Carolina Beach at Kittyhawk until they described them in the *Journal of the Society of Western Engineers.* Probably it was their intention to electrify the world when they were quite satisfied with what they had accomplished at Dayton. A remarkable point is that they apparently have ***not been satisfied.*** This is in part, we believe, due to troubles, if they can be called troubles, with their motor, which developed some very troublesome idiosyncrasies. It gave 24-h.p. quite regularly on the bench for apparently as long as they cared to run it, or at any rate for as long as it had been run. It also apparently gave 24-h.p. when mounted on the aeroplane, and when flight commenced. It kept up its full power fairly well for a quarter of an hour or twenty minutes, and then gradually fell off to about 14-h.p. This, no doubt, has prevented their giving such practical demonstrations of the art of flying as they would have wished. Probably also there are considerations of patents. On reflection, we are disposed to rate very little the suggestions put forward by M. Archdeacon and others, that the Wrights have nothing patentable, and that their success is entirely due to their skill. It is mainly due to their skill, no doubt, but it is impossible to deny that it is also due to a very large extent to the improvements in construction to which we have referred above. These are ingenious, they are decidedly novel, and they have produced a new and useful effect never before approached. If this is not good subject matter for a patent, we would like to ask what is? From this point of view, of course, a motor-driven aeroplane would come under any patents they may have taken out for the gliding machine we illustrate. But that ought to be protection, ample and sufficient. That they may have made other improvements of distinct importance, and that they wish to be fully protected is but probable. These considerations would alone be sufficient to explain their reticence. Further reasons may be their natural disinclination to have experiments, which they still obviously regard as only tentative—"the things they have done but earnest of the things that they will do"—witnessed by a gaping and unsympathetic mob.

How far they have gone in the effort to secure secrecy and prevent premature publication of their doings has been shown by an incident unearthed by the enterprising M. Coquelle. It appears that the *Dayton Daily News* had a sensational article already in type last September, describing the Wrights' experiments. It was only with great difficulty that they succeeded at the last moment (for a consideration) in preventing its appearance. M. Coquelle actually obtained possession of a copy of this suppressed paper, containing the report to which we refer, provided with the following headlines:—

"Victorious Experiments of Flying Machine."
"Wright Aeroplane comes safely to Earth after a
Remarkable flight near Dayton."

The whole article was some fifty lines in length, and was illustrated by portraits of the two Wrights. Its existence surely is the most complete confirmation, if any were needed, of the evidence we have brought forward above.

In any case, whether Governments are generous or stingy, and whether patents have been applied for or not, their unique skill, if they are willing to condescend publicly to exhibit their prowess in Europe or America, ought certainly to ensure them an ample return for the rest of their days. And there is every reason to believe that they also regard the honour of having been the first to solve the problem of the ages, as no small part of the reward they have so justly earned.

AERONAUTICS.

Mr. Wilson Again.

CONSIDERING the present position of the free flight question, the statement put forward by Mr. Wilson (who, it will be remembered, has recently occupied himself with experiments at Wembley Park of a more or less *opera bouffe* character) that he is *determined* to start within a few months on a voyage in his new "Clipper of the Clouds" from the Watkin Tower, has a distinctly comic significance.

Milan Exhibition Prizes.

IN connection with the Milan Exhibition of 1906, considerable sums are to be dedicated to prizes for aeronautical competitions. These will involve all sorts of appliances from navigable balloons to kites, and the highest prize of 50,000 lire is offered for a dirigible airship, while the next prize of 10,000 lire is for a competition of flying machines furnished with motors and carrying an operator. One would rather prefer that the relative value of the prizes were reversed, for though it is not stated, it appears to be understood that the dirigible airship competition is confined to navigable balloons. There are also competitions for which prizes of 2,000 lire will be offered for "flying machines"—that is, of course, gliding aeroplanes without motors.

Rushing the North Pole.

WHENEVER an aeronautical triumph is chronicled, one always hears of some enthusiast or self-advertiser determining to reach the Pole by means of the new locomotion. The Knabenschue dirigible balloon has been exciting a good deal of interest in the United States, and one of the results has been that a certain Mr. Walter Wellman, of Washington, a correspondent of the *Chicago Record-Herald*, who has, it is stated, made two successful trips to Polar regions, has decided on an attempt to reach the North Pole by means of an airship of the Santos Dumont type. It is to be 196 ft. long and 49 ft. in diameter, and will have a capacity of 226,000 cubic ft., being capable of carrying a total load of 15,300 lbs. It is anticipated that it will be able to maintain itself in the air for 30 days, and carry an 8,000 lb. cargo. The airship, it is stated, is to be designed and run by M. Santos Dumont himself, to be built by Godard, of Paris, to be ready in the month of April, to be at the headquarters of the expedition at Spitzbergen in July, and to reach the Pole with Mr. Wellman at—some subsequent date.

* * *

Lord Justice Fletcher Moulton.

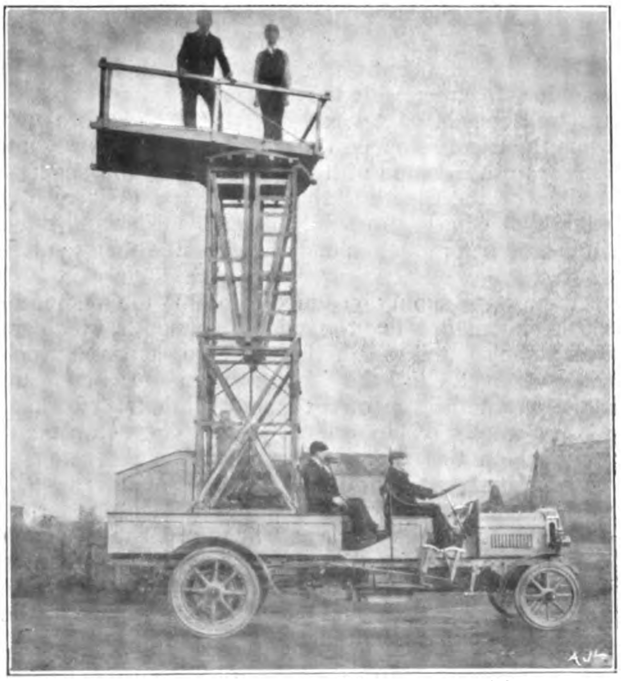
EVERYONE connected with the engineering industries will join in congratulations to Mr. Fletcher Moulton, who so recently gave his inspiring speech upon the *pros* and *cons* of the motor car, on his appointment as Lord Justice of Appeal. The appointment of a barrister direct to the Court of Appeal, without having been previously made an ordinary judge, is a high distinction, though no one will for a moment dispute that in Mr. Fletcher Moulton's case it is fully and completely justified. He is admittedly our highest authority on patent law, and a man of high scientific attainments. As he is also possessed of great legal knowledge and astonishing forensic ability, his practice has undoubtedly for many years been one of the most lucrative at the Bar. The new Lord Justice, who was educated at Kingswood School and St. John's College, Cambridge, is one of the few examples of Senior Wranglers who have distinguished themselves subsequently, as he gained this high distinction in the old days when the acquirements of a Senior Wrangler were considerably different from what they are at present. His attractive and humorous personality will, however, doubtless be seriously missed by brother barristers in the Patent and Chancery Bar.

Motoring Burglars.

AFTER the exploits of the auto-highwaymen to which we refer this week, the performances of the auto-burglars who burgled up at Great Wigston, near Leicester, from a motor car, read rather tamely. Nevertheless these also were scientific and progressive gentlemen, more scientific in some respects than the French auto-highwaymen, for besides their automobile they had one of the finest assortments of burglars' tools ever seen, and such was their skill and address that they succeeded in boring fourteen holes in a modern up-to-date safe.

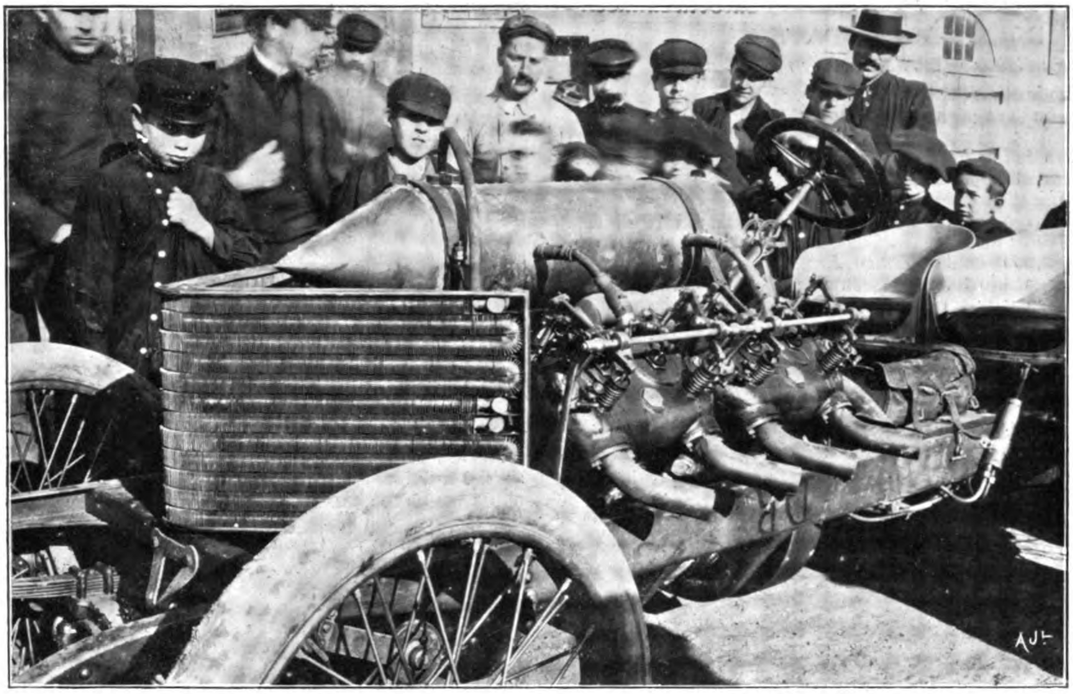
Royal Patronage.

THE German Automobile Club has been granted the patronage of the Kaiser, and has been authorised to take the title of the "Kaiserlicher Automobil Club."



It is a significant fact that even the Electric Tramway turns in distress to the Motor Car, for most of the go-ahead Tramway Companies now employ Motor-driven Power Wagons for the repair of their trolley wire. We give an illustration of one of these vehicles which has been built by the Lancashire Steam Wagon Co. for the Belfast Corporation.

RACES, RECORDS, AND TRIALS.



View of the 200-h.p. Engine in the Darracq Racer, with which Hemery last week broke the world's flying kilometre speed record. Four cylinders of 170 mm. bore by 140 mm. stroke are placed diagonally on each side of the crank-chamber, those opposite one another operating in pairs upon the same crank pins. The inlet-valves, placed centrally above the cylinders, and the exhaust-valves, which also project upward from the cylinder heads, are all operated by their push-rods through small rock-levers. Above the engine is seen the water tank, with the V-shaped radiator in front of it; the petrol tank is fixed behind the seat. With its wire wheels, shod with Dunlop tyres, this fast machine weighs 990 kilogs.

Flying Kilometre World's Record.

ON November 18th and 25th last, in dealing with the official Continental record of 23 seconds for the flying kilometre made by F. Dufaux at Ostend, we incidentally drew attention to the fact that the world's record still remained with Clifford Earp and his 6-cylinder Napier with 21⅖ secs., although this time had been also attained—unfortunately on an "unofficial road"—by Baras, on a Darracq car. We pointed out that until the "time" had been repeated by a Darracq car on the same road (the Arles-Salon, which had since received official recognition), it could not rank as an official world's record. The Darracq firm have evidently taken the hint, as last week, by way of a brilliant wind-up to 1905, Hemery, on a 200-h.p. Darracq car, not only scored the necessary time, but went a good deal better, he being timed for 20⅗ secs. = 174·75 kiloms. per hour! (108.5 m.p.h.). Hemery made four tries, and in one of these came within one-fifth of a second of repeating his record time. The car was a special racing monster weighing 990 kilogs., fitted with two 4-cylinder 100-h.p. motors, coupled in V-form.

The "Grand Prix de l'Automobile Club de France."

IT is under the above name that the big French racing event for 1906 is to be officially known. The choice of a circuit is still a very vexed question in France. The Fontainebleau district is a first favourite, in spite of municipal baits, in the form of big cash subscriptions being offered to procure the adoption. In principle, the rules will, of course, be based upon those put forward last year when the Grand Prix was first mooted. Three cars only of the same make will be permitted, whether entered by the manufacturers or others holding sub-licences to manufacture. A very drastic alteration is proposed in the rules hitherto governing the renewals of tyres, replenishment of petrol, oil, spare parts, &c. These, it is said, will only be permitted at fixed official points, and all changes of tyres, &c., must be made by the driver and mechanician *only*.

Hydra Cup.

HITHERTO this cup has been offered for motor cycle record times over 100 kilometres on the track. At a meeting of the Hydra firm, the donors of the cup, it has been decided to offer it for competition to 1-cylinder voiturettes, with a maximum cylinder capacity of one litre, and of a maximum weight, including the carriage body and magneto, of 350 kilogs. Two seats must be occupied in the trial, representing a total ballast weight of 140 kilogs. The contest is to take place over a distance of about 300 kiloms. in one stage. The winner cannot be challenged for the period of one month after securing the cup. This is a consideration, as the holder receives 10 francs a day until his time is lowered. The entry fee is 50 francs. Only two cars are allowed for each maker. The opening contest will probably take place in May.

CORRESPONDENCE.

*** *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion, or containing queries.*

DIRECT-DRIVE PATENT.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—We notice that the Renault Company are apparently proposing to take action against those of the trade who are using the live-axle and shaft transmission, claiming to possess a master patent upon this system dating from February, 1899. We also see that the Whitney patent of 1898 is being quoted as anticipatory of the Renault, but, if it is of any use to those in the trade who are using this system of transmission, we can inform them that a still earlier anticipation is to be found in Mr. Chas. E. Duryea's car, which won the Chicago 2,000 Dollar *Times-Herald* Race in 1895. This vehicle was designed in 1893, and completed in the following year. It was fitted with gear transmission, giving three speeds forward and reverse, with live axle and bevel gear, practically the same as so largely in use to-day. Mr. Duryea abandoned it the following year in favour of belt transmission, which at that time was being asked for by the public, and subsequently finding the direct chain transmission superior to either, he never went back to the shaft and bevel gear, but photographs and drawings can be produced at any time should they be needed for the protection of the British industry in the matter.

Yours faithfully,
FOR THE DURYEA MOTOR COMPANY.

Coventry, Dec. 30th.

A RACING PROPOSITION.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Is it not possible now to put the "improvement of the breed" idea out of its position of monopolist of racing interest, and to run races for *sport* and pleasure? I can remember years ago Mr. Edge advocating *small car* races, cars of, say, 6-h.p. only, and built or racing—sort of half-raters, as it were.

The classification could be very simple, say, maximum piston area and minimum weight, as the conditions would be the same for all.

The initial expense of these small cars would be small, and their running expenses ditto, so that many could afford to participate.

With such small cars it might very well be possible for the A.C.G.B.I. to get permission to race round one of the many large parks occasionally, or it might be possible to build a track, without very great expense, of ordinary road material, and about two miles in circumference.

Track racing has been going on for some time in America, but the want of limit to size of car has made it the sport (?) of professional drivers paid to take great risks.

Though I suggest that "improvement of the breed" should not enter into the framing of the rules, I feel quite sure that some very useful information would be obtained from these miniature racing vehicles. I don't think racers of any sort can be built and run without useful information resulting.

There is one other result which might have far-reaching effects, viz., encouragement and work for the small makers. Doubtless many amateur drivers would have ideas of their own for the improvement of their racers, and in some cases would like the entire car built to their ideas. This is where the small makers with original ideas would score, as it is well known that big manufacturers with order books well filled with orders for standard goods object very much to building special lines or departing from their standards. Why not in addition to promoting sport, also encourage the man of original ideas?

Yours faithfully,
ERNEST H. ARNOTT.

Jan. 2, 1906.

6 CYLINDERS v. 4 CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—We have read with interest Mr. Edge's letter on 6-cylinder cars, and desire to endorse what he says with reference to the advantages of six cylinders. While every credit should be given to Mr. Edge as the first seller of 6-cylinder cars, there are others who were not slow to recognise the merits of the 6-cylinder motor.

In 1904 we decided to build 6-cylinder motors, and exhibited our first 6-cylinder motor at the Paris Exhibition of that year.

The 6-cylinder Rolls-Royce has, we are glad to state, created a reputation for itself which is second to none, and we can endorse Mr. Edge's statement that the difficulty is not to procure orders, but to produce cars in sufficiently large numbers to satisfy the demand that there undoubtedly is for good 6-cylinder automobiles. So much so is this the case that we are engaged with arrangements for considerably extending our works at Manchester, with a view to still further increasing our output.

We have, from time to time, given drives on our 6-cylinder cars to our friends in the automobile trade, and, as a result, we think we can point to more than one instance in which traders who were formerly engaged in the sale of foreign-made cars are now engaged in producing 6-cylinder British-made motors.

It is true that our output and that of other manufacturers of 6-cylinder cars in this country may up to the present be small, but this is a misfortune which can be—and doubtless will be—remedied very shortly. We hope, therefore, that Mr. Edge, when writing in future of the 6-cylinder movement, will not overlook the fact that other British firms have for some time past been engaged in making and selling 6-cylinder cars which have proved highly satisfactory to their purchasers.

Your obedient servants,
C. S. ROLLS AND CO.

December 30, 1905.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I do not know whether your correspondent, Wilfred Dawson's letter is inspired by Mr. Edge or not, but it looks suspiciously like it. I have been following most carefully the letters appearing on the 4 *v.* 6-cylinder controversy, and I would point out that the objection made by Mr. Jarrott, the length of wheel base of the 6-cylinder car, has been carefully left unanswered both by Mr. Edge and his other correspondents. It must be admitted that the 6-cylinder engine is one-third *longer* than a 4-cylinder one, and, therefore, if the design of the car is on the principle of proper distribution of weight over the four wheels, then the front wheels of the 6-cylinder car have to be carried forward, correspondingly increasing the wheel base nearly one foot, a very considerable amount in these days, when we are trying to keep wheel bases as short as possible. A very noticeable example of this was shown on the Panhard and Levassor stand at Olympia this year. The 6-cylinder car exhibited by that well-known firm was of colossal length, and was almost as long in *front* of the dashboard as it was *behind*.

Therefore, I think Mr. Jarrott's contention was a very obvious one, and certainly one with which I am in full accord. Six cylinders do mean an increased wheel base.

The 6-cylinder Napier must be badly designed if the front wheels have been brought back as suggested by your correspondent, thus throwing *all* the weight of the motor on these two steering wheels, and at the same time making the car resemble in appearance those ungainly-looking motor omnibuses—some of which are on the streets—which have two feet of bonnet projecting in *front* of the front wheels.

Yours truly,
H. GLADSTONE COLEBROOK.

Guildown, Coolhurst Road,
Crouch End.

THE NEW TOURIST TROPHY REGULATIONS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—The inefficiency of the steam engine, as compared with the internal combustion engine, has provoked much amusing discussion in connection with the Tourist Trophy regulations, and I have just seen your issue of the 16th inst., on my return to London.

My old friend Mr. Coleman, of the White Company, seems to have taken personal offence because I asked a friend of his it he could account for the Club's proposal to allow a specially large consumption of fuel for steam cars in any other way than that they (the committee) realised the inefficiency of the steam car system.

To use Mr. Coleman's own words, he "apparently does not think. . . ." his friend "sufficiently capable" of replying, and he has come into the lists to defend him.

It seems to me useless in these modern days to discuss at any length the relative efficiency of the internal combustion and the steam boiler systems, *i.e.*, the direct and the indirect methods of obtaining power from fuel, for no amount of talking or writing round the point can, of course, alter the known facts.

The only point was whether steam cars and petrol cars should have a different allowance according to their respective efficiencies, *i.e.*, whether the Tourist Trophy Race should be a handicap; this would be perfectly fair if the Tourist Trophy were purely a sporting event of no commercial value, but the best horse can only be proved by a scratch race, and the only fair way to run an event such as the

Trophy Race is to let everyone go in on equal terms and not to favour either one system or another.

To favour steam cars by allowing them a special advantage over petrol cars would be decidedly unfair on the many engineers who, on account of its greater efficiency and other advantages for road locomotion, have developed and perfected the internal combustion engine for our use.

Personally, I should be interested to see the race run on a basis of price instead of quantity of fuel, but this opens up a new question which presents difficulties such as the possibility of a car winning the race which, on account of smoke or smell when "running light" would be quite unsuitable for ordinary use. Nevertheless it is hoped that this method of limitation, which has already been proposed, will be considered by the Club with a view to its adoption another year.

The question of the best basis—quantity or price—is well worthy of discussion, but whatever basis is adopted from year to year, it should in my humble opinion be the same for all systems—whether efficient or inefficient.

Yours truly,

CHAS. S. ROLLS.

29th December, 1905.

BRITISH *versus* FOREIGN CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I read only last week a speech made by a well-known agent for the sale of a well-known British car, and as I had only just returned from the Paris Salon it was particularly interesting to me as it touched upon that very much discussed question, "Should foreign cars be taxed?" The individual in question was addressing a number of—presumably—working men, and he was lamenting the fact that a grave injustice was being done to the working men of England because perfidious and clever foreigners were allowed to import cars into this country free of duty, and in return, would allow no English cars into their own countries without payment of a certain customs duty.

As a result of this the aforesaid and ill-used agent could not compete with his British-made goods in the aforesaid foreign countries and had been compelled to erect his own (*sic*) factories in certain foreign countries he mentioned in order to meet the foreigner on his own ground and on his own terms. All this and much more on the same lines was held forth, it being most carefully omitted that if foreign cars *had* been taxed in the past the motor industry in this country would have been, and would be now, considerably retarded. The real fact that instead of erecting his *own* factories he had induced enterprising foreigners to build *their* factories and take a licence from him for manufacturing the cars in which he was interested—thus putting money into his own personal British pocket which would otherwise have been diverted into other sources—did not come within the knowledge of the audience, so the point was allowed as a fair argument.

I do not wish, Sir, to start a discussion in your journal on "protection," but a certain section of the motor industry in this country is so complacent on its position that I would like to mention a few hard solid facts for its benefit.

The British firms showing at the Paris Show this year numbered three, viz., Argyll, Star, and Wolseley, and I think these firms are deserving of the highest praise for their representation of the industry in Great Britain. At the same time, I do not suppose that they went there because they expected to find a large number of foreigners buying their cars. The idea was rather to emphasise their position as being three of the leading English firms, and the policy was undoubtedly good and correct. I believe that at least two of the firms have representatives in France, and consequently do a certain amount of business there. Anyhow, no one can say that the demand for English-built cars abroad is very great.

And, as outlined in the earlier part of my letter, we are asked to believe that this is due to the fact that a duty has to be added to the price of these cars before they can enter foreign markets, and consequently they are unable to compete with success against foreign cars in their own countries. And yet the point that struck me most this year at the Paris Salon was the Italian invasion. More than a dozen Italian firms took a space, and a very brave show they made. It is unnecessary for me to mention names, but they were there to do business, and some of them were doing business, and have been doing good business in France—regardless of any duty—selling cars to French agents, and to the French and foreign buying public. Belgium was also well represented, and at least two makes of these cars are in great demand in France, and do well, and last, but not least, Germany was exhibiting, and a large number of German cars are sold in France every year, as well as in other countries, including a ready sale in America, where a 45 per cent. tariff is imposed on imported cars.

Speaking of America reminds me that all the leading French firms do excellent business there with their cars in spite of the said 45 per cent. duty.

Therefore, I think I can rightly and truthfully say that it is not the imposition of a duty on British-built cars which prevents their sale into foreign countries, which is responsible for their not being asked for and sought after, and this being so, then what is the matter with British firms and British goods? Is it because they are not advertised? Surely not. With a powerful and responsible Press backing them up, this department cannot be considered as neglected. Is it lack of merit as compared with the leading Continental makes? I dare not assert this or else I shall be accused of belittling the English industry, but at the same time I am curious for an answer. I have read so much lately as to England's position in the world's motor industry that I should like some further information. If anyone can enlighten me, I am sure their information will be of interest to the rest of your readers.

Yours truly,

Dec. 28th. CHAS. JARROTT.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I have just read a letter in the *Evening Standard* from Mr. Charles Jarrott, the champion of the foreign motor car manufacturer, in which he refers to a speech of mine at Hastings. Possibly the same letter has been received by you, and I therefore forward you my reply. Unfortunately his statements as to what was said at this meeting are incorrect; the position that I put forward was a simple and conclusive one. I pointed out that an order for Napier cars had been received from abroad, which represented something over £30,000 being paid in wages to execute this order, but that while this was satisfactory from the British motor trade point of view at the present moment, I could not look forward to this satisfaction continuing for many years, and that in the relatively near future all these orders which are at present coming to Great Britain for British cars would merely result, as soon as the factory could be worked, in this business being done in British-designed and British-named motor cars, but built in the particular foreign country where the orders are coming from at present. The reason for this was that, whilst at the moment the six-cylinder principle has not been successfully made abroad, the demand for it is here, and the only way for a foreigner to meet it was for him to buy six-cylinder cars from England. The foreign country, however, apparently thinks their workmen of more importance than your correspondent, and, therefore, very properly from their point of view, puts up barriers in the way of tariff charges which make it uncommercial to manufacture the articles in Great Britain and import them to the foreign countries.

I carefully pointed out that this system in vogue in foreign countries of tariff did not injure the British capitalist to such an extent as the British workmen, as it makes very little difference to me whether the Napier cars are manufactured in Great Britain, in America, France, or Italy, but it does make a difference to the British workman who would have been paid wages if all Napier motor cars manufactured in the world were manufactured in Great Britain, and it appears to me from the British working man's point of view, anything that can keep factories in this country, and prevent them going abroad into these tariff protected countries, would be an advantage to the British working man.

Your correspondent, as is usual with those who are really interested in the importation of foreign goods without considering the good of the country, makes general statements, but gives no facts. I have given facts, and I leave these facts to enable your readers to draw their own conclusions. His reference to the fact that, although America has a duty of 45 per cent., that it is still quite easy for countries with great energy to do business there, is simply untrue, and in his efforts to make out that the British manufacturer and the British working man is incompetent and useless, he has endeavoured to prove this by stating that foreigners do import large quantities of motor cars to America. If he will carefully look up the proper records of the country, he will find that 95 per cent. of the motor car business in America is done in American-made cars, and that only a few very rich people buy foreign cars; and there is little doubt but that for the fact of the American tariff, America having started so late in the motor industry, it would have been entirely overrun with motor cars foreign to America, but, owing to their protective tariff, they have been enabled to build up a business, and have to-day at least 95 per cent. of the business done in the country, and the importing business, in proportion to the growth of the motor car business is becoming less and less every year. It seems to me unfortunate that a gentleman whose living depends upon the sale of foreign cars should try to so mislead the public, and one can only assume that it is caused through failure to establish a semi-British car that he is supposed to be interested in. If he will tell us how manufacturers in this country can compete on equal terms with manufacturers of countries who are protected from foreign invasion by a tariff wall, but who are allowed to augment their production by the addition of the British trade, and to trade as freely with Great Britain as a British manufacturer, as it is well known every manufacturer that increases his output enormously decreases the manufacturing expense, and if he can tell us why the factory located, say, in Germany, and supplying goods to a combined one hundred million of people in Germany and Great Britain, as compared with the British manufacturer merely supplying to the British forty millions, is not at an advantage, I should be interested. It seems to me that, in view of the great handicap the British trade has suffered, it is simply marvellous the way that they have steadily rolled back the foreign trade, which only a few years ago had the whole of the business in this country, and now this year the larger proportion is being done by the British manufacturer, who, despite the fact he started making modern motor cars years after his foreign competitor, and has suffered from many restrictive measures and secret attacks written by ostensibly Britons like your correspondent, but whose chief livelihood depends on his faithful service to foreign manufacturers. I ask you, Sir, is such an one likely to have an unbiassed view of the movement that, thanks to the British workman, is steadily pushing out foreign work, with the consequent increase of wages paid to our fellow-countrymen.

Yours truly,
S. F. EDGE.

* * * *

COMMERCIAL POINTS.

Cars for Electioneering Purposes.

MR. E. H. LANCASTER, Managing Director of the Clément Motor Company, 3 Leicester Street, Leicester Square, W.C., announces that he has several Cléments for sale suitable for electioneering purposes, and these can be obtained upon very reasonable terms. Mr. Lancaster will supply the details, on request.

A CHANCE to obtain cars for electioneering purposes is offered by the White Steam Car Company, of King Street, Regent Street, who have received an exceptionally early batch of the new 18-h.p. White Steam Cars, some of which, consequently, they have ready for immediate delivery.

THE Continental Tyre Company desire that all motor car agents whose names were not included in the 1905 edition of their "Handbook for Automobilists in Great Britain and Ireland," should communicate with them at 102–108, Clerkenwell Road, London, E.C., and ask for a form to be filled in with particulars, which will be inserted free of charge. Also any suggestions for improving or making the 1906 edition more complete will be welcomed, and receive every consideration.

THE Straker Steam Vehicle Company, Limited, have changed their name to that of Sidney Straker and Squire, Limited. The business of Straker and Squire has been incorporated under the new title, so that in future everything will be conducted by the new firm. The company requiring larger premises, have left 9, Bush Lane, and are now occupying No. 5, Nelson Square, Blackfriars Road, as temporary offices, pending the completion of new administrative buildings, repair shops, and garage in Nelson Square, so that all communications from this date must be sent to Sidney Straker and Squire, Limited, Nelson Square, Blackfriars Road, London, S.E. Mr. Sidney Straker advises us that, with the exception of the company's works located in Bristol, Sidney Straker and Squire, Limited, is the only firm with which he (Mr. Sidney Straker) is connected.

MESSRS. SHIPPEY BROS., of 13, King Street, Cheapside, inform us that they have purchased the entire stock of the Holden Motor Bicycles from the Motor Traction Company, Ltd., at a large cash discount from stock book prices, which purchace will enable them to sell these machines at about half the original manufactured price.

THE Continental Tyre Company, owing to the increase of their business in Lancashire and Yorkshire, have opened a new wholesale depôt at 255, Deansgate, Manchester. At this depôt a large and well-assorted stock of "Continental" motor tyres, cycle tyres, and cycle rubber goods will be kept, and from where prompt deliveries can be effected when required. Mr. Albert Harness is in charge of this new depôt.

THERE has just been installed at the Panhard-Levassor Repair Works, Kimberley Road, Willesden Lane, an up-to-date plant for the making of wheels, and a large stock of thoroughly-seasoned cleft oak for spokes has been procured. Orders for wheels of any design can now, we learn, be quickly executed. Special shops have been built for re-painting customers' cars, this portion of the work being undertaken during the time the mechanism of the car is being overhauled.

* * * *

CLUBS AND ASSOCIATIONS.

A.C.G.B.I.

ON January 11th, a smoking concert takes place at the Club; in January 18th, Mr. A. G. New, technical editor of THE AUTOMOTOR JOURNAL, will read a paper on "The Tourist Trophy," and amongst others who will give papers on later dates are Colonel Holden, upon the subject of "Ignition"; Mr. Dugald Clerk, "Cylinder Capacity and Horse-power"; and Mr. E. Manville, "Tramways and Motor 'Buses."

Automobile Association.

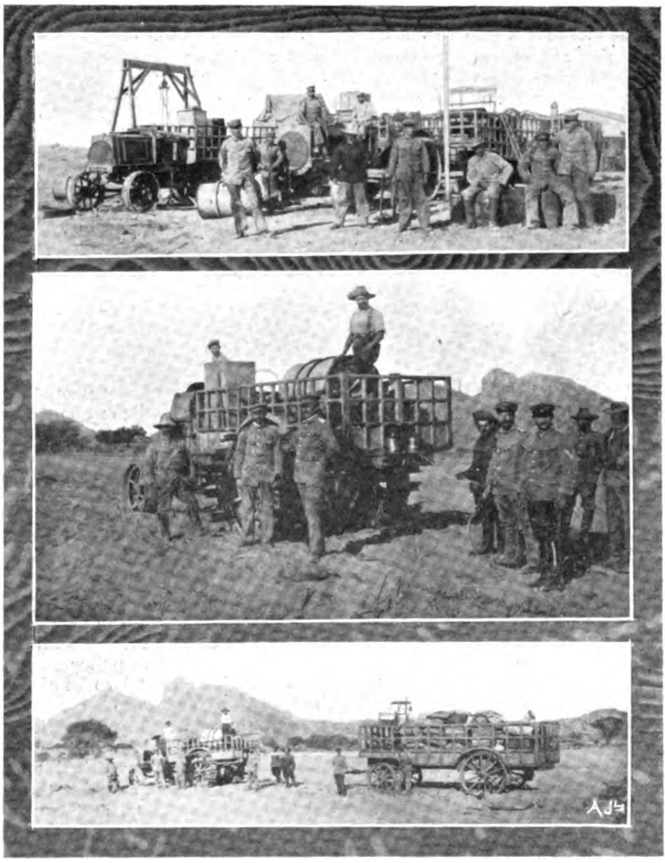
THE first Annual Dinner of the Association will be held at the Trocadero Restaurant on January 25th. A musical entertainment will follow the banquet.

Northamptonshire A.C.

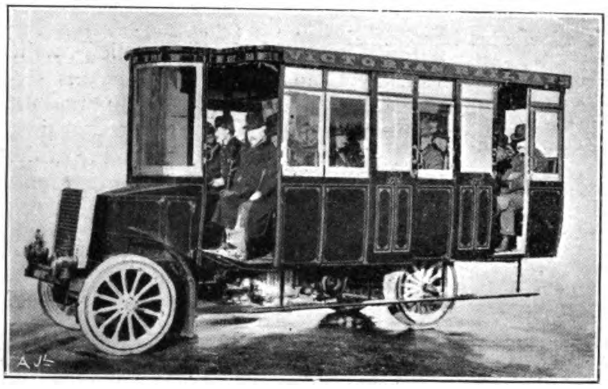
AT a recent meeting of motorists at Northampton, it was decided to form a club under the above title. Mr. C. W. Bartholomew, of Blakeley Hall, presided.

Motor Union Meetings in 1906.

THE monthly meetings of the General Committee during the year are proposed to be held in London except the following:— May (Birmingham), July (Bath), September (York).



The industrial vehicle is being introduced by the Germans into the most out-of-the-way colonies. The three views which we reproduce above, show a couple of "N.A.G." lurries at Swakopmund, in South West Africa, on the journey, being loaded up, and using the winding gear with which they are provided. The rough kind of ground they have to travel over is well shown in the two lower views by the depth to which the wheels of the lurries have sunk into the sand.



MOTOR 'BUSES IN AUSTRALIA.—One of the six steam vehicles which are in operation by the Victorian Railway Department. The chassis have been supplied by Messrs. Clarkson, and are of the standard single-deck type already familiar in this country. The bodies, which are of a peculiar pattern, are being built at Newport in the Government workshops.

MOTOR BOATING.

Motor Boat Meeting in Australia.

Sydney had its first motor boat races on November 13th in connection with the Balmain Regatta. Under the circumstances, a good showing was made of starters in the two events in the programme. The first was a handicap for boats under 25ft. (6 starters), secured by F. P. Cooper's little De Dion, whose time was 12h. 32m. 5s. (1 min. allowance); 2nd, J. Leslie's Nogi, 12h. 33m. 50s. (9½ min.); and 3rd, A. W. Joss's Bullet, 12h. 33m. 50s. (scratch)—a result which commands respect for the handicapper.

In the second handicap event for boats over 25ft. (8 starters) the first three were: 1, C. A. Marshall's Togo, 1h. 43m. 20s. (25 min.); 2, Dr. G. Read's Asthore, 1h. 43m. 45s. (20½ min.); 3, J. E. Clumery's Bona, 1h. 45m. 40s. (13 min.)—another triumph for the handicapper.

Coupe du Salon.

Like most of the motor boat meetings of 1905, the last of the year—held on Sunday last on the Seine above Paris—fared no better than its predecessors. So far as racing craft were concerned, Antoinette III was the solitary starter, and even this speedy boat had to retire after covering one lap, through a frozen carburettor. For the rest, Forcès-Pas, the Mors-engined cruiser, was timed for the three laps, equal to a total distance of 28·05 kiloms., in 56m. 57s., no other contestant coming within 25 mins. of her time.

⊗ ⊗ ⊗ ⊗

MOTOR CYCLING.

The results of Class D for motor cycles, in the Melbourne-Sydney reliability contest, are given elsewhere in the present issue, in connection with the general account of the run.

Motor Roads—for Motors or Promoters?

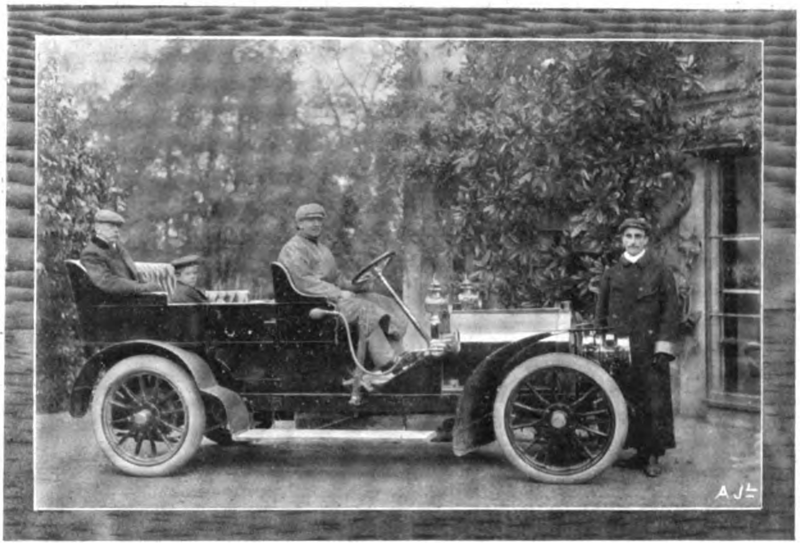
What we knew and prophesied would happen has already taken place. The financial gentlemen who are *determined* to promote (and if possible pass) a bill for making a motor road to Brighton, have evoked from an anti-motoring clergyman, to wit, the Rev. J. P. Bacon-Phillips, who writes from Crowhurst Rectory, Sussex, observations redolent of anti-automobilistic *odium theologicum*. He has written to the *Standard* the following letter:—

> "I regret to see that considerable opposition is manifesting itself against the proposal to construct a motor road from London to Brighton. I have recently been staying at Redhill, and the enormous number of motor cars on the main Brighton road I calculate exceeds every other kind of vehicle by at least six to one.
>
> "I am aware that Brighton has been abnormally full this Christmas, but the fact remains that if the number of cars increase by the same ratio as they have done during the last twelve months, this famous road will become absolutely impassable for every other kind of vehicle. The best solution to this difficult problem is the new motor road, and as this proposal emanates from the motorists themselves, it seems to me to be very short-sighted policy to offer any opposition to it. Our highways were not constructed for motor traffic, and, therefore, separate motor roads appear to me a step in the right direction."

A better illustration of the arguments which we have always advanced against a separate motor road could scarcely be asked for. The reverend anti-automobilist embraces, it will be seen, with effusion the opportunity offered of getting motorists off the ordinary roads, and he adds—we think without justification—that the proposal emanates from motorists themselves. If he had added the little particle "pro" and cut off the "ists," his statements would be more in accordance with facts. The whole proposal, indeed, suggests most forcibly that it is designed in the interests of the promoter first and of the motor second.

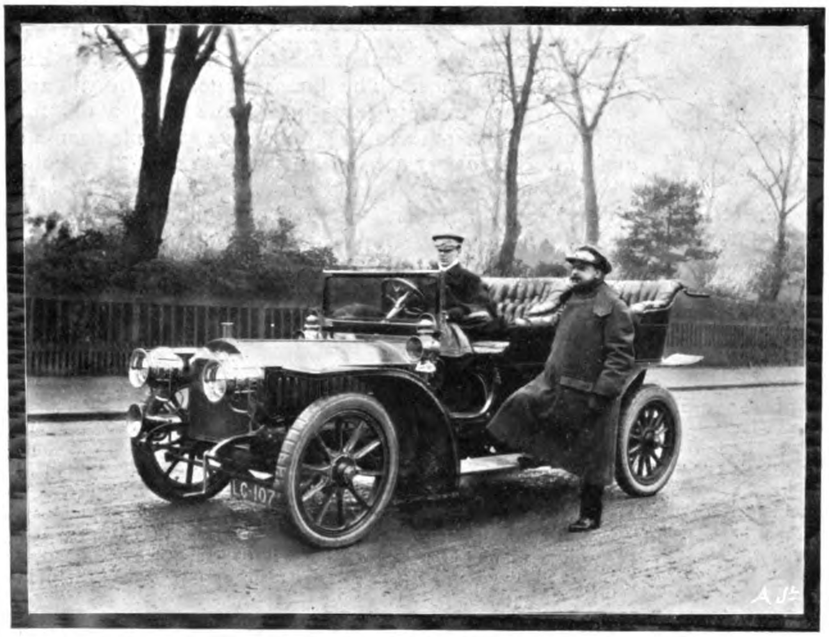
Motor 'Bus Service Resumed.

The motor omnibus services of the Great Eastern Railway, in different parts of Essex and Suffolk, which were temporarily discontinued, are, it is announced, to be resumed at an early date.



Copyright.

"Three Generations and a Car," is the title which Mr. C. B. Fry, the popular cricketer, has given to the above picture, the explanation being that Mr. Fry is himself at the wheel of this 16-h.p. De Dietrich, in the back are seated Mr. J. L. Fry, his father, and Mr. Steven Fry, his son.



Mr. William Le Queux, the well-known novelist, in his 40-h.p. Napier car, in which he is making a 5,000 miles tour in England and Wales.

Another Testimonial for Municipal Trading.

A RATHER comic state of affairs, and one which provides another of the many satires on municipal trading that the attempts of civic bodies to engage in commerce have provided us with, prevails at the present moment at Birkenhead and Liverpool. The traffic between Liverpool and the suburb on the other side of the Mersey has, till recent times, been carried on mainly, if not exclusively, by the steam ferry-boat service which is run by the Birkenhead Corporation. Many people who have suffered from this service will remember it well, and they will recollect that recently one of the ferry-boats tipped the motor car of Mr. Cinquevalli into the Mersey. The monopoly which the municipal ferry-boats once enjoyed, however, is now seriously threatened by the Mersey Tunnel Railway, which is much quicker and more expeditious. The Corporation are countering by running the electric trams, which they, of course, own, so as to feed the ferry-boats, but so as to expose intending passengers by the Tunnel Railway to the maximum of inconvenience. Thereupon the Railway Company started a service of motor 'buses to feed their railways, and enable Liverpudlians to arrive in Birkenhead without having to expose themselves to the drawbacks of the ferry-boat service. Will it be believed that the Corporation are applying for an injunction to prevent the Railway Company from running these motor 'buses to bring people to their termini? Here we have a Corporation absolutely interfering with the convenience of its own ratepayers as a consequence of its being permitted to engage in trade. A worse or more damaging commentary on municipal trading it would be difficult to find. Whether the Corporation succeeds in obtaining its injunction or not, however, need, it seems to us, trouble the Railway Company but little. All that the company need do is to register another company with the customary seven signatories, and with funds supplied by the Railway Company to run the 'bus service. In that case it will be unimportant whether an injunction is granted against the Railway Company or not. Probably, if this course is adopted, it will be found that the litigation will not go very far, and we shall not be likely to hear much more of that terrible word "injunction."

New Royal Cars.

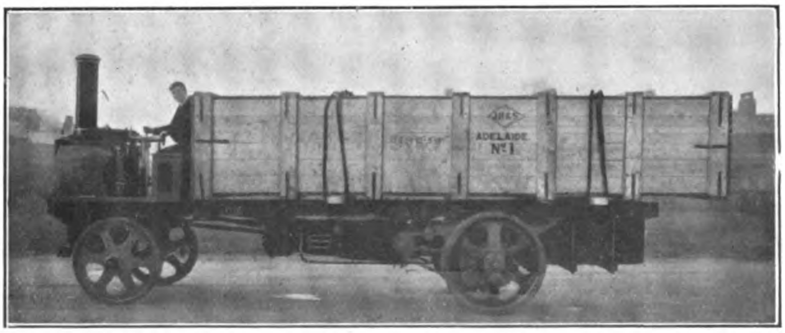
THE 35–45-h.p. motor carriage built by the Daimler Motor Company to the special order of the King, was delivered by the Company to His Majesty at Sandringham on Christmas Day. Her Royal Highness Princess Henry of Battenburg has also ordered a car from the Company of 30–40-h.p.

Electioneering and Motors.

THE North London Automobile Club, through their hon. secretary, Mr. Charles Smith, of Avondale, Brownlow Road, New Southgate, N., will be pleased to hear from motorists in the North London district who are willing to lend their cars to assist Colonel Bowles (president of the club) for the General Election. Colonel Bowles is in accord with the abolition of the speed-limit, and is prepared to support a measure requiring the universal lighting of all vehicles after dark.

An Eccentric Jump-Spark.

E. J. Pennington, under the name of the Continental Engineering Company, has bobbed up once more in the United States. This time it is a wonderful sparking-plug which, as usual, is to revolutionise the motor industry. From the only description at present to hand the idea seems as egregious as the famous "mingling" spark theory expounded by Pennington many years ago. We learn from the *Grand Rapids Press* that the plug has a combustion chamber of its own, from which it flashes forth flame in order to ignite the mixture in the cylinders. The spark itself, we learn from the same source, "jumps about eccentrically." No wonder!



A USEFUL TEST LOAD.—One of the Lancashire Steam Wagons starting on a trial run, loaded with a crate containing the Chassis of a Leyland Petrol Omnibus, for shipment to South Australia.

The Kaiser's Chauffeur.

Werner, the well-known Continental racing chauffeur, has, since the death of Mr. Gray Dinsmore, whom he used to drive, been selected by Kaiser Wilhelm as his driver.

To Advise the Police.

The Secretary of State has appointed Mr. W. Worby Beaumont, M.I.M.E., to act as adviser to the Commissioner of Metropolitan Police in matters relating to motor cars and omnibuses.

Motor Lifeboats.

Under the will of Mr. Frederick Kitchen, of Drws-y-Coed, Trefriw, Carnarvon, the National Lifeboat Institution receives over £6,000 for "the purchase of a motor lifeboat, to be placed on the West Coast of England."

Salon Lottery Prize.

Mdlle. Bocaudé, a daughter of one of the directors of the Gillet-Forest Company, is the lucky winner of the first prize, an 8-h.p. De Dion car, in the Paris Salon lottery.

Scavenging Authorities Take Note.

In a recent case, in which a motorist was summoned before the stipendiary magistrate at Westminster for having the number of his car obscured, it was proved that it was merely covered with mud owing to the state of the streets. Under these circumstances the magistrate refused to convict.

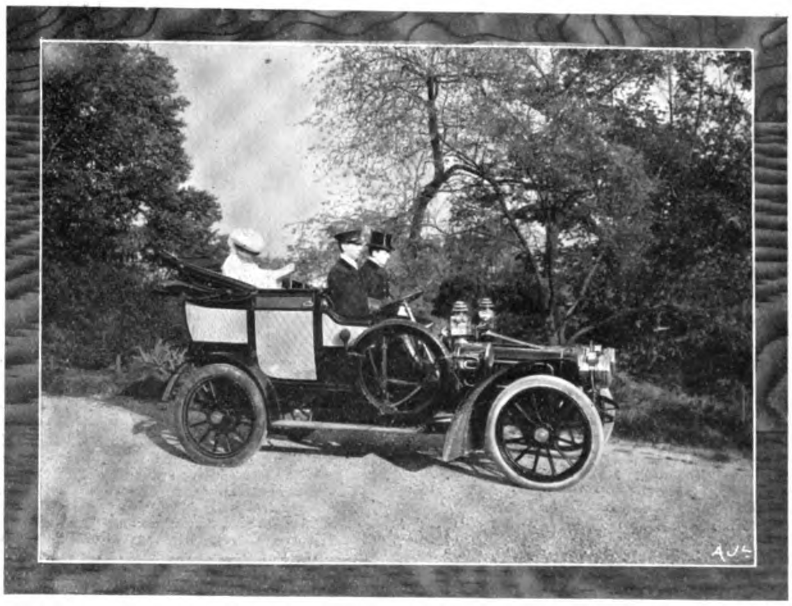
Dangerous Tramway Brakes.

As a shocking example of the dangers the public, in some districts, run from the high speed and imperfect brakes of electric tramcars, we draw attention to the fact that the Executive Council of the Amalgamated Association of Tramway and Vehicle Workers recently passed a resolution as follows:—

> "That there is urgent need in the interests both of the travelling public and the tramway employés that the Board of Trade should compel the various tramway undertakings to adopt a standard type of brake for all tramways, which shall be simple in construction and independent of wires and complicated mechanism."

Driving Licences and their Renewal.

Among the absurdities of the 1903 Act, attention has been drawn to the situation which arises in reference to the renewal of a licence which the driver, according to the police, must carry with him on all occasions when he drives his car. Licences have to be renewed, and if you send them for renewal you cannot in consequence safely venture to drive your car till you get them back again. A licence-holder recently wrote to the County Council pointing this out and asking them if they could provide him with any form to show that the licence was in their possession for the purpose of renewal. He received the reply from the official that all he could suggest was that the licence should be forwarded for renewal on some day on which the holder did not wish to go motoring, and that it would be returned to him the same day. As a matter of fact, it is very unusual for a licence to be renewed the same day that the application is made, and it seems a preposterous oversight of the legislature (though just the sort of thing that one might have expected), for car owners, numbers of whom use them for business purposes, to be in this way deprived of the use of their cars for one or more days in the year at the discretion of the local authorities.



Mrs. Leslie Carter, the well-known American actress, in her park landaulette.

Glidden Tour.

Mr. Charles J. Glidden, when last heard from, had run his total mileage, travelled round and about the world, up to 27,574 miles. He is now on his second tour of the world, having driven 2,474 miles to a north-westerly point in India since he left Bombay, and traversed the famous Kyber Pass into Afghanistan.

New Badges for Public Service Drivers.

In a few days London cab and 'bus drivers will have to wear the new registration badge on their arms. Each type has had a distinctive colour allotted, that selected for motor cabs being green with white figures, and for motor omnibuses blue with white figures. *All* conductors will have red badges with white figures.

Driving and Mechanical Proficiency Certificates.

The next examination for these Automobile Club certificates will be held at 119, Piccadilly, on January 17th, at 10 a.m. Candidates can take either or both examinations. Particulars can be obtained from the club secretary.

Racing a Hare.

Most motorists have observed, when driving at night time in the country, the curious manner in which rabbits seem to be attracted by the head-lights and speed of the car, often with very disastrous results to themselves. In regard to this the Wolseley motor Company write us, enclosing a photograph of a very fine hare, which tried conclusions with one of the new 32-h.p. Siddeley cars along a deserted stretch of road between Birmingham and London. The occupants of the car were surprised to see a big animal racing in front of them. It maintained a very high rate of speed for a minute or two, then suddenly collapsed and fell, the inference being that it had overstrained itself, for no part of the car had touched it. The hare was quite dead, and without any apparent mark of injury on it.

NEW COMPANIES REGISTERED.

Automobile Contract Company (Limited), 5, Augustus Street, Albany Street, N.W.—Capital, £1,000 in £1 shares. Object, to carry on the business of vendors of motor carriages of all kinds on the hire-purchase system, &c. First directors: Sir Samuel Scott, M.P., C. H. Burnard, and S. Lee.

W. Bath and Son (Limited), 25, Victoria Street, Westminster.—Capital, £50,000 in £1 shares (25,000 cumulative preference). Object, to carry on the business of manufacturers and dealers in engines, motors, and carriages propelled by mechanical power. First directors: H. W. Sale, W. B. Bath, and W. Savage.

Chapman Von Sobbe and Co. (Limited).—Capital, £5,000 in £1 shares. Object, to take over the business of motor car agents carried on at Liverpool as Chapman Von Sobbe and Co. F. C. Bowring, E. N. Thornewill, C. N. Watson, G. Chapman, and F. A. Von Sobbe.

Hammon and Smith (Limited), Dale Street, Coventry.—Capital £2,000 in £1 shares. Object, to carry on the business of engineers, makers, and repairers of motors, motor cycles, &c. First directors: W. G. Hammon, H. N. Smith, W. G. Hammon, jun., J. Hale, T. A. Gardiner, A. W. Thompson, and J. T. Fazakarley.

Hertfordshire County Automobile Club (Limited).—Registered with twenty members, each liable for 2*s*. 6*d*. in the event of winding up.

Light Motors (Limited). — Capital, £2,000 in £1 shares. Object, to carry on the business of manufacturers and repairers of motor-propelled cycles, &c.

Portsmouth and Southsea Engineering and Motor Car Company (Limited), 29, Landport Terrace, Southsea, Hants.—Capital, £1,000 in £1 shares. Object, to acquire lands, and buildings at Landport Terrace, Southsea, and to carry on the business of engineers, motor car manufacturers, &c. First directors: E. H. Boulton, T. Mattinson, and A. Talker.

Resistant Pneumatics (Limited). — Capital, £12,000 in £1 shares. Object, to adopt an agreement with the Richardson and Price Engineering Company, Limited, and to carry on the business of manufacturers of pneumatic and other tyres.

J. Schofield and Sons (Limited).—Capital, £1,000 in £1 shares. Object, to acquire the business carried on by H. Schofield, as J. Schofield and Sons, at Heybrook, Rochdale, dealers in motors, carriages, &c.

⁂

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

4098. 27th February, 1905 Improvements in Change-Speed Gear. John Johnston, 3, Ruvigny Mansions, Putney, S.W., and Harry W. Buddicom, Penbedw, Nannerch, near Mold, Flint, North Wales. This invention relates to change-speed gear for use upon motor-driven vehicles of the type wherein the power from the motor shaft is transmitted to the driven shaft through sets of sun and planet gear of different values, some of the sun-wheels of which are adapted to be respectively retarded to give changes in speed or direction. There are three figures. Fig. 1 is a longitudinal section of a gear according to this invention. A small sun-bevel wheel, *a*, is keyed or pinned to the driving shaft, *b*. A second sun-bevel wheel or pinion, *c*. of equal diameter, but with teeth oppositely arranged in relation to the first, *a*, is loosely mounted on the same shaft, *b*. These two sun-wheels, *a* and *c*, are hereinafter referred to as the fixed and loose sun pinions respectively. Upon the outer end of the extended boss or sleeve, *d*, of the loose sun pinion, *c*, is rigidly mounted, one element, *e*, of an expanding or other clutch, forming also a brake drum, referred to as the second speed drum, acting as a brake drum on its outer periphery, and a clutch surface on its inner periphery, adapted to be engaged by a clutch member, *f*, on the driving shaft, *b*. Loosely mounted on the same boss, *d*, is a sun-wheel, *g*, also having a brake drum, *h*, rigidly mounted on its extended boss, referred to as the third speed drum. A sun-wheel, *i*, of equal diameter to the one, *g*, just referred to, but with oppositely arranged teeth, is loosely mounted at the opposite side of the gear, and has the reverse brake drum, *k*, keyed on its boss. The latter sun-wheel, *i*, runs loosely on a sleeve, *l*, which is keyed to the driven shaft, *m*, and is loose on the driving shaft, *b*. From this sleeve, *l*, a number of radiating arms, *n*, extend, having a circumferential flange to which the bosses, *o*, are attached by screws, the bosses embracing the ends of radial pins, *r*, on which latter double planet pinions, *p q*, are mounted. The planet pinions engage the sun-wheels and pinions, and the radial arms or concave disc, *n*, form a driving member for transmitting the torque from the planet pinions to the driven shaft. The planet pinions are double or in pairs. Each has a pinion, *p*, meshing between the sun pinions, *c* and *a*. The planet pinions are, as before stated, supported on radial pins, *r*, carried by or extending from a boss, *s*, loosely mounted on the boss, *t*, of the fixed sun-pinion, *a*, the planet pinions running loosely on the pins. The whole of the gearing is encased by an oil-tight casing, *u*, so that it runs continuously in an oil bath.—December 13th, 1905.

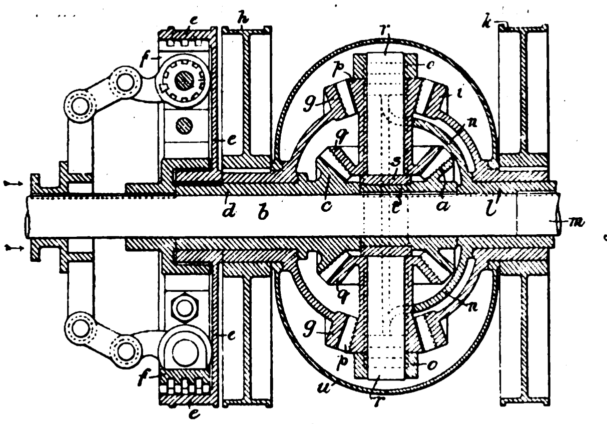


Fig. 1.

6919. 1st April, 1905. Improvements in Carburettors particularly for Fluid-Pressure Engines. Edmund W. Lewis, 2, Albany Road, Coventry. This is a peculiar title, as a "fluid pressure" engine is usually taken to indicate a steam engine, and the title should apparently have been, "Improvements in Vaporisers for Internal Combustion Engines." A small quantity of air is drawn past the jet in the usual way, so as to pick up the required amount of fuel. This charge is then passed through a vaporiser, after which additional cold air is added. The chief advantages of this arrangement are that only a small quantity of cold air is admitted to the vaporiser, and, therefore, the amount of heat necessary to keep it at the proper temperature is small, and that the temperature of the complete charge going to the engine is low in that a small amount only passes through the vaporiser. It is preferred to heat the vaporiser at starting with a lamp which is automatically extinguished when the engine has started up, after which the heating is effected by the exhaust gases. There are three figures. Fig. 1 is a central vertical section of this vaporiser. It comprises a fuel nozzle, A, and a constricted air passage, B, adjacent thereto, constructed so that a small quantity of air will take up a relatively large quantity of fuel from the nozzle, A, under the action of the engine suction in the ordinary manner. The spray-chamber, B, of this carburetting device is suitably attached to the vaporiser. A set of tubes is fixed into end plates, D. Beneath the tubes C. is arranged a heating lamp, E, which may be fed with the same fuel by means of a constant level float device. The hot gases from this lamp pass around the vaporiser tubes, C, which resemble those of a fire or water tube boiler, and pass out through a chimney or outlet, G, at the top of the vaporiser chamber. The vaporiser chamber is divided into two parts vertically, so that the vaporiser tubes, C, and their end plates, D, may be withdrawn for cleaning purposes. Adjacent to this heating chamber, E¹, is an exhaust passage forming part of the exhaust system of the engine. Passages are made in the wall dividing the exhaust passage from the heating chamber, E¹, at the top and bottom thereof, in such a manner that a by-pass is formed from the exhaust passage through the heating chamber, E¹. Preferably these passages are covered by hinged flaps, L, adapted in one position to close the passages and in the other position to close in the one case the orifice, E², over the heating lamp, E, and in the other case the outlet, E³, from the top of the heating chamber, E¹. The object of these flaps is to extinguish the heating lamp as soon as the engine has started up. These flaps are connected together so as to operate simultaneously. The vaporiser tubes, C, communicate with a mixing chamber, N, arranged at right angles to the vaporiser tubes. There are two sets of holes in the perforated piston, O, which is closed at both ends. These holes are elongated, and one set is adjacent to the inlet, N², to the mixing chamber, N. In the wall of the mixing chamber, N, and above the normal position of this first set are extra air intakes, P, adapted to communicate with the elongated holes, O¹, when the piston rises. The second set of holes, O² are arranged at the end of the piston, and are normally covered, but when the piston rises, these holes, O², are partly uncovered.—December 13th, 1905.

PASSING EVENTS.

The Approaching Election. A proclamation has been issued by a number of charming Peeresses to motor car owners supplicating them to supply cars during the forthcoming struggle on behalf of Unionist candidates in London. It is not suggested by the ladies in question that any pledge should be asked for, much less exacted, from the candidates as to whether they will support the automobilist movement on the lines on which we have frequently insisted, and to which the Automobile Club and the Motor Union require subscriptions. We embrace the occasion, therefore, once more to enforce the principle that automobilists should make a rule, quite irrespective of political parties, of only supplying the asked-for assistance in cases in which the prospective candidates are willing to subscribe to the articles of faith to which we have already referred editorially, and which appeared in our advertisement pages last week. It is superfluous to urge once more that for the vast majority of motor car owners automobilism is, or should be, of paramount interest, and that however much any individual car owner may be feeling inclined to accede to the appeal of the ladies to whom we refer, he will be acting in a decidedly short-sighted manner unless he is reasonably assured that the candidate whom he is helping is willing to assist the automobile movement. We have already explained that the Club and Motor Union Joint Committee has arranged to organise all offers of cars which may be placed at its disposal in such a way as to afford support only to candidates who are willing to pledge themselves to measures which all automobilists desire to see passed. In spite, therefore, of all seductions which may be brought to bear upon them, car owners who are willing to lend their cars for electioneering purposes will be adopting the wise course if they confine their action to putting themselves into communication with the secretary of the Joint Committee, and allow their arrangements to be guided entirely by him. The importance of the coming election as regards the future of the automobile movement is very accurately gauged by our enemies, and the Chairman of the Highways Protection League has also issued a proclamation proposing that wherever possible statements should be obtained from candidates which will pledge them to an anti-automobile attitude. Needless to say, candidates who give the kind of answers required by the Highways Protection League will *not* be supported by the automobile forces, or by the phalanx of cars which the Joint Committee has at its disposal. Everyone, therefore, who places a car at the Committee's disposal, will know, at any rate, that it is safe from the clutches of the Highways Protection League.

◆ ◆ ◆

The Views of Magistrates on the Situation. "Arising out of that," as the framers of supplementary questions in the House of Commons are fond of saying, it is of interest to draw the attention of everyone, and particularly of all Parliamentary candidates who may be hesitating in regard to subscribing the articles of faith required of them by the club and the Motor Union, that as regards the arbitrary speed limit enforced by the existing Act, a very large number of magistrates who have had practical experience of its working are in favour of the repeal of that restriction. No less than 173 magistrates of the United Kingdom, including representatives of the Benches of nearly every county in the Kingdom, have put their names to a statement expressing "their strong sense of dissatisfaction with regard to the operation of the clauses in the Act of 1903 which regulate the speed of motor cars," and consider "that the first clause of the said Act (about reckless driving) is amply sufficient for the purpose." Considering that such a phalanx of magistrates, who have had at first hand opportunities of judging of the working of the 20 mile limit clause, takes this pronounced view, Parliamentary candidates who may be doubtful on the question should feel little hesitation in deciding as these magistrates have done. The support that they will get by doing so is worth having, for, as we have pointed out, the most powerful support that any candidate can obtain at the polls is that of an adequate squadron of motor cars, and he will be provided with such a phalanx if he subscribes to the articles of faith which have been drawn up. In that case both the Automobile Club and the Union will do their utmost to see that he gets adequate car support, and the utmost that these two great bodies together can effect is considerable!

◆ ◆ ◆

Unconsidered Military Aspects of Automobilism. It has hitherto always been necessary, in order to provide adequately for the defence of the country, to adopt means by which an extra supply of draught horses can be obtained, in good and reliable condition for army use at short notice, immediately on the outbreak of war. Of course it will be understood that horses employed for military purposes fall into two great classes. There is the trained military horse, the quadruped that forms the unit of a squadron of cavalry, or has been trained (in the artillery) to bring guns into action, and to tolerate, if not to enjoy, the discharge of them at sham fights and manœuvres, and that type of horse may be regarded as a permanent member of the staff. You cannot take a horse from the shafts of a London 'bus or a London cab and expect him to perform this kind of duty with satisfaction to his employers. There is also, however, the equally large, if not larger, class of horses employed in transport and commissariat duty. An army, as Napoleon said, marches on its stomach, and unless the commissariat department is in good working order, and that has hitherto practically meant being well horsed, the mobility and efficiency of an army in the field will be sadly circumscribed.

The way in which the War Office—the same practice has also been adopted by foreign states—has met the necessity of supplying an immense number of extra horses for commissariat and transport work in time of war, has been to subventionise the great horse employing companies, primarily the 'bus companies, secondarily the railway companies, thirdly the cab organisations, and after them private firms like brewers and contractors. In return for certain payments these firms register the horses that they will be able to place at the Government's disposal when required to do so. Hitherto the system has worked fairly well. At any rate the number of 'bus horses who disappeared from London during the South African War, and left their bones to whiten on the veldt, was very considerable.

◆ ◆ ◆

An Altered Problem. But now the conditions are rapidly changing. That most remarkable phenomenon of London locomotion, the successful advent of the motor 'bus, and the less conspicuous, though hardly less successful, advent of the motor lurry for railway, brewery, and heavy transport work generally, is already beginning to make itself felt, and it is understood that the War Office is even now beginning to experience increased difficulty in finding the number of horses it requires for registration in accordance with the arrangement which we have referred to. In a year's time this difficulty will be greatly accentuated, and it does not require the eye of a prophet to foresee that in a very limited period the 'bus, tram and heavy traction horse generally will be as extinct as the rhamphorhynchus. Even before that day dawns, probably even our War Office will have recognised that whether horses continue to be necessary or not for cavalry and field artillery, the day of their successful employment for military transport will have long passed away. Various military authorities, as we have reported, have from time to time drawn attention to the imminence of this problem, and a very sensible proposal has now been made by "an officer"—whose identity we do not think it would be difficult to fathom—that instead of the registration of horses, and the subventionisation of their owners, the War Office should in future arrange with the 'bus companies to adopt 'bus chassis of a uniform type, with removable or detachable bodies. Instead of registering horses, the course would then be to register a chassis, and when the War Office required them they would call upon the 'bus company to remove their 'bus bodies and send the chassis on to the War Office, who would then provide them with the lurry or other body which they required for use in the field. The adoption of this proposal would mean that the War Office would be able to provide itself with a magnificent reserve of transport power—more reliable and accessible than ever before, while the money paid in subventionising the companies would benefit a new industry to a marked degree and assist in the general adoption of the self-propelled 'bus and transport vehicle. The proposal is a thoroughly practical and well-considered one, and with a new broom at the War Office, it is, perhaps, not too much to hope that we may ultimately see it adopted.

◆ ◆ ◆

Imports and Exports. On another page we furnish statistics concerning imports and exports—carefully compiled by THE AUTOMOTOR JOURNAL from official sources — which embody practically all the reliable information that is available on the subject. Previous to the year 1900, when, of course, neither automobile exports nor imports were deemed to be of sufficient importance, no special trade returns were available—motor cars, motor cycles, parts and accessories being all included in the grandly comprehensive but hopelessly unenlightening title of "goods, unenumerated, manufactured." During 1900 and 1901 they were included under the general heading of "carriages, wagonettes, carts, &c.," so that the returns were still of very limited usefulness, and even in 1902 and 1903, when cars and motor cycles were placed under a heading of their own, they were lumped together. Only for 1904 and 1905 have they been properly placed under separate and adequately descriptive headings. It is only the figures for the last two years therefore, that, have any real significance, interesting in a way as are those given previously, but these recent figures, as will be seen when examined in detail, prove enormously instructive. In 1904 the value of cars imported to the United Kingdom was just over two millions sterling. In 1905 the same imports rose to £2,438,000, showing an increase of nearly half a million, whilst "parts" amount in all to nearly a million. Lumping the total value of the imports of cars, motor cycles, parts, and accessories, brought into the United Kingdom altogether, the figures for last year amount in all to a value of £3,446,966 as against approximately £2,472,000 in 1904, so that automobile imports taken altogether have increased by an amount represented in pounds sterling by nearly a million.

◆ ◆ ◆

And their Significance. As representing the relative advantages to the foreign car builder, however, these figures require some correction, for the large item of upwards of £900,000 for motor car parts represents, no doubt, engines, gear-boxes, axles, springs, and other items which are put together in this country to form complete cars. The main lesson of the statistics, however, is that the imports into Great Britain of finished cars still continue to increase, and to increase more rapidly than formerly. In fact, out of the thirty-four leading lines of manufactured goods specified by the Board of Trade returns, *motor car imports come ninth in actual value*, while among those that represent larger sums only a few exceed the motor car figures by anything like large amounts.

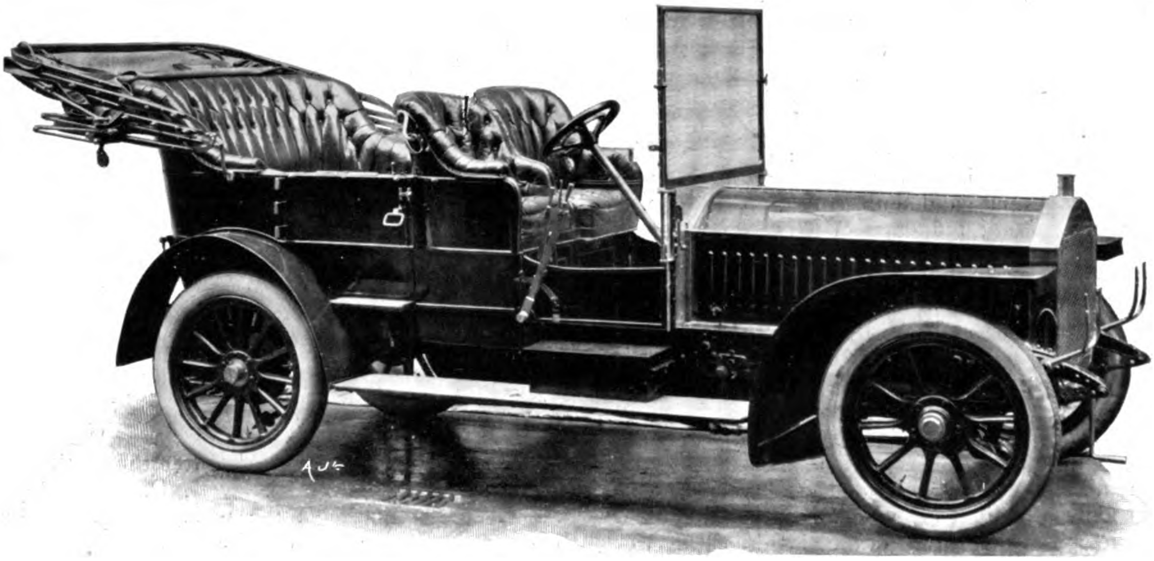
Now we know from the statistics of exhibitions and from various other more or less reliable sources, that the number of cars bought in this country represents a far greater increase than the 25 per cent. shown by the importation figures. It therefore follows that the output of British car builders must have gone up by leaps and bounds during the past year, and that the British industry is now obtaining a far larger share of home business. Even were this not the case, however, the mere fact that foreign imports of finished cars still continue to increase is a very satisfactory sign in itself, for it at least indicates the manner in which the cars sold in 1904 have led to the sale of even more during last year. This is a decidedly healthy state of affairs, and will no doubt continue more and more markedly for some considerable time to come. We commend the figures which we publish, therefore, to the careful consideration of the new Parliament, so that when certain few rabid cranks make their customary attempts to cripple the growing industry by ill-advised and narrow-minded legislative restrictions, their ravings may receive a suitable cold douche of statistics.

"In Splendour Bright."

THE Surrey Joint Committee has authorised the expenditure of £52 7*s.* to provide the Chief Constable, Capt. Sant, with a new and, considering the price, presumably resplendent uniform—at the expense of the county. This is the sort of recklessness that results from raking in too many fines from motorists, in accomplishing which Capt. Sant has been singularly successful. Before the days of motor car fines, it was probably not customary to deck out chief constables with such gorgeousness as to cost £52 7*s.* a time. Motorists who have doubtless provided the greater part of the £52 7*s.* will probably be anxious to see what sort of appearance he presents when thus embellished. He ought at least to be placed on exhibition in his new disguise on Saturdays and Sundays on the Ripley Road. If horses (and donkeys) take fright at the portent, the Anti-automobilist (and donkey-loving) Joint Committee will only have their own extravagance to blame.

THE 1906 SIX-CYLINDER NAPIER CARS.—PART I.

ON November 18th last, THE AUTOMOTOR JOURNAL contained illustrated descriptions of a large number of those new cars which are being turned out at the present time by well-known firms, and amongst these was included—on pages 1412 and 1413—an article dealing in a general manner with the latest Napier models. Attention was then drawn more especially to the remarkable equipment of the Napier factory, to the extraordinary extent to which cost of production is rendered subservient to nicety and refinement of finish and design, and to the great demand that has been created by this most progressive firm for their 6-cylinder cars. A few words were moreover devoted to the special advantages resulting from the use of six cylinders, and it was not only pointed out that even greater flexibility and smoothness of running can be obtained than with any lesser number of cylinders, but we were careful to state how extremely important to the success of such engines is absolute synchronism between cylinder and cylinder. The article in question was also accompanied by three excellent illustrations of the 60 h.p. chassis, all of which—especially the large-scale view from above—will be found very useful in connection with the present fuller description of these extremely successful vehicles, for we are now able to give information of a more detailed character concerning their actual construction.



One of the latest 60-h.p. six-cylinder Napier Cars.

At that time, moreover, we had not had any practical experience on the road with the new 60-h.p. vehicle, and could not therefore speak from personal observation concerning its actual capabilities, although it was a foregone conclusion that the many improvements which were so noticeable in its design would make it an even more ideal car than the 40-h.p. model. Quite recently, however, we have been able to accept Mr. Edge's offer to place one of these vehicles at our disposal, and we then took a good long spin out into the country and back, handling the car ourselves for a considerable portion of the distance. To say that it fully came up to our expectations is but a mild expression of the only opinion that could be formed of its performance, for it is really astounding that any 60-h.p. car should be quite as easily controlled as—and far more comfortable than—most low-powered cars when travelling at a mere walking speed in traffic, and that there should yet be such an enormous amount of power available at a moment's notice. Even to-day, in spite of the wonderful developments that are known by all to have been made in petrol engine manufacture and in motor car construction, it must strike all motorists as marvellous that six cylinders having pistons 5 inches in diameter can be made to work in such perfect unison with one another—even when the engine is running at a speed well under 200 revs. per min.—that no one can detect the slightest indication of the individual impulses as they are transmitted from each cylinder in turn to the crankshaft. Although geared (with 36-inch wheels) to 55·42 miles per hour at the normal speed of 1,600 revs. per min., the car can be made to run—except of course when ascending a hill of very pronounced gradient—with absolute regularity, and never a miss-fire of the engine, as slowly as 5 or 6 miles per hour on the top speed, merely by closing down the throttle-lever. In a moment, however, it will accelerate, without noise or apparent strain, immediately the throttle is opened up, and then it is that the remarkably constant "torque" of this powerful engine is rendered so conspicuously apparent. Truly, it is not too much to say that the 60-h.p. Napier car enables the full benefits to be derived from an extremely powerful engine, and is at the same time totally free from the majority of drawbacks which have in the past been associated with vehicles having enormous engines. The metal-to-metal clutch, too, is largely responsible for the smooth running and easy control of this beautiful piece of machinery, for it slips just sufficiently when first brought into use to prevent any of those sudden shocks which are so unpleasant to the occupants and so detrimental to the whole mechanism, but it holds well when once the car is under way.

Of the three 6-cylinder models now being built, it is those of the live-axle type, in particular, that represent, at the moment, the last word of the Napier Company on motor car design, for, whereas the chain-driven 40-h.p. car is but little altered for the present year, the 60-h.p. vehicle is entirely new, and the live-axle 40-h.p. model is practically a cross between the two. Although, therefore, our illustrations will enable us to deal with, and show, the construction of all three models in this article, we propose to devote our attention chiefly to the 60-h.p. car.

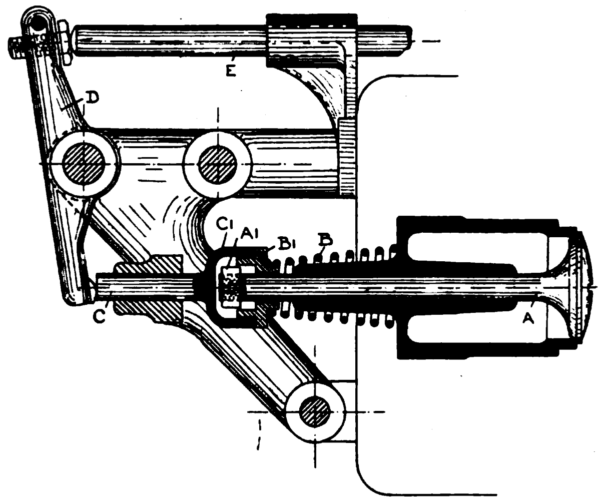
Initially, it may be stated that the 40-h.p. chain-driven car has a 9 ft. 8 ins. wheel-base with a 4 ft. 8 ins. track, and is fitted with 880 by 120 mm., and 870 by 90 mm. tyres on its rear and front wheels respectively. Except that the wheel-base is 10 ft. 4½ ins., the live-axle 40-h.p. model is similar in those respects. The 40-h.p. engine has cylinders of 4 ins. bore and 4 ins. stroke, and its mechanically-operated inlet-valves are above the exhaust-valves. On the 60-h.p. vehicle, however, the engine has all the valves arranged alongside one another, and the bore and stroke are 5 ins. and 4 ins. respectively. The wheel base of this car is 10 ft. 9 ins., and all four wheels have 880 by 120 mm. tyres. It is usually geared either so that it would run at 52·2 m.p.h., or at 72·5 m.p.h. on the top speed, when the engine is running at 1,600 revs. per min.

(*To be continued.*)

THE NEW DURYEA VALVE.

Readers of our issue dated October 31st, 1903, will recall to mind that in it we devoted a special article to the description of an inlet valve invented by Mr. R. E. Phillips, A.M.I.C.E., and used by him on his private car at that time. Since then, however, very little has been heard of this device, so it is especially interesting to find that the Duryea engines are being fitted with it for the ensuing season. Perhaps Mr. Phillip's own term, "Auto-mechanical" best describes its principle, which is that of having an atmospheric valve under positive control. Our illustration shows the device as fitted to the Duryea engine, and it will be noticed that the short rods, C, operate, not upon the valve spindle, A, but upon the valve spring, B. When relieved from the pressure of the spring, therefore, the valve is free to open atmospherically. An advantage claimed for this device is that it enables the engine to run better because it allows the valve to "time" itself somewhat for variations of engine speed. In action it differs from atmospheric valves pure and simple in that the valve is not under the constant influence of a spring, and it is also unlike an ordinary mechanically-operated valve in that it can, within limits, choose its own time for opening and closing. Theoretically, therefore, it neutralises disadvantages in both types, since it removes the necessity for using very weak springs, which need careful adjustment, and it also reduces the importance of extreme accuracy in "setting" the operating mechanism.

Instead of allowing the valve to be wholly atmospheric, however, the operating-gear is so made as to mechanically open and close the valve should it tend to stick. There is only a limited clearance, it will be noticed, between the end of the valve-spindle and the cap, C^1, of the rod, C, so the valve is very quickly pushed open if it does not move of its own accord. Similarily, the spring, B, positively closes the valve—through contact between the collars, B^1 and A^1—after the suction-stroke. In the Duryea engines, rock levers, D, are employed to transmit the motion from the push-rods, E; the valves being placed in the heads of the horizontal cylinders.



The Duryea Inlet Valve.—Drawing showing the new operating mechanism by which the push-rod acts first on the valve-spring instead of on the valve-rod—with the result that the valve itself is virtually atmospheric in action, although subject to mechanical control should it not operate properly of its own accord.

A Valuable Guarantee.

The Automobile Club still continues its useful activity in examining intending motor car drivers, and providing them with driving and mechanical efficiency certificates, which will be a guarantee to their employers that they possess a reasonable degree of competence. Some 2,000 certificates of this character were issued to owners and paid drivers up to the 31st of December, 1905, and the club anticipate that at least 10,000 will be issued during the present year. As inquiry into character is also made by the club before granting a certificate, the driver who possesses such a document proves, not only that he is a competent driver and mechanic, but also that he is a reliable employee. An important feature of the examinations is that they are held at a variety of different centres throughout the kingdom, and as the secretary of the club gives the fullest information on the subject, any candidates either in London or the provinces will be able to ascertain by letter when and where the nearest examination at which he can present himself will be held.

Scavengers as Expert Speed Witnesses.

Of all the funny witnesses that the police have ever brought forward to prove excessive speed on the part of motor cars, street scavengers may be cited as probably the weirdest. Their notions of pace, almost needless to say, are largely suggested by the dust and mud carts with which they are familiar. Such a case occurred recently at Aberdeen, where a local citizen was hauled before the Sheriff and charged with driving at excessive speed, to wit, upwards of twenty miles an hour. Among the witnesses against him were three scavengers, who declared that they beheld the car proceeding along the street at an excessive rate of speed. In cross-examination, one of the scavengers was asked what he thought the speed actually was, and declared (naturally enough amid "laughter") that it must have been quite four miles an hour. Others, however, maintained that it was twenty-three miles an hour, and Sheriff Begg, disregarding the evidence of the first scavenger, and more or less "begging the question," convicted the accused and fined him £3. After this, as the schoolboy said, "What need have we of any further false witnesses?"

THE FIAT COMMERCIAL VEHICLES.

It is one of the best auguries for the ensured success of the motor 'bus movement, that those very firms who are in the front rank of motor pleasure vehicle construction, should be already bringing their practical experience to bear on the design of thoroughly sound chassis suitable for withstanding the much more severe and prolonged strains imposed on commercial vehicles

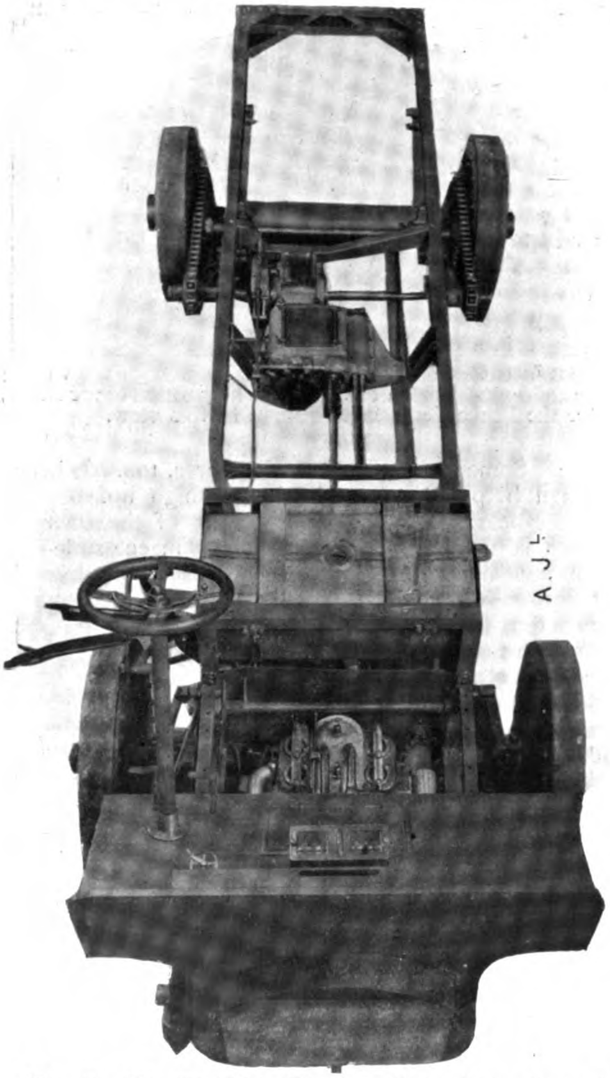


Fig. 2.—The Fiat 'Bus Chassis. View from above of the 24-h.p. 'Bus Chassis, showing the general arrangement of the mechanism.

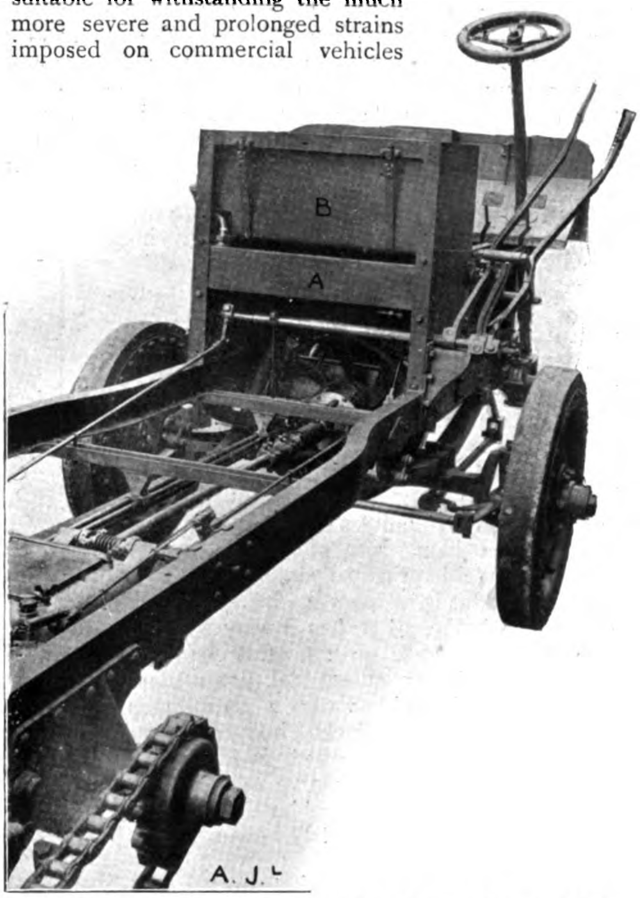

Fig. 3.—The Fiat 'Bus Chassis. View showing the position of the Petrol Tank, B, also the Water Tank, A, for cooling the Foot Brakes. The Steering Heads and Tie-bar are also visible in this illustration, which gives prominence to the arrangement of the Change-speed and Brake Levers.

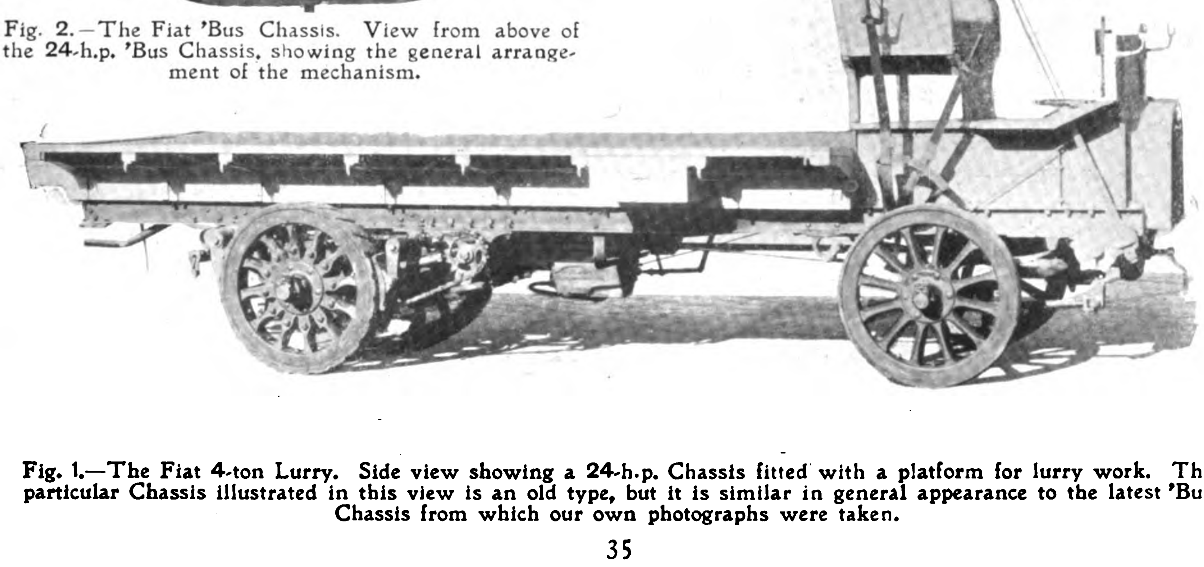

Fig. 1.—The Fiat 4-ton Lurry. Side view showing a 24-h.p. Chassis fitted with a platform for lurry work. The particular Chassis illustrated in this view is an old type, but it is similar in general appearance to the latest 'Bus Chassis from which our own photographs were taken.

—especially those used for public service work. For some time past the Fiat Company have ranked among such go-ahead firms, and the heavy vehicles which they have constructed have done yeoman service in their own country, where they have been extensively employed by the Italian Army. But these vehicles have only recently been brought to this country, and were publicly exhibited for the first time, by Fiat Motors, Limited, at Olympia. They are, at present, like the Fiat touring models, made in two sizes, and the engines with which they are fitted are similar to those used for the touring cars. The smaller vehicle —which, like the other, is of the chain-driven type—has the 16-h.p. engine, while the 24-h.p. motor is fitted in the larger model; both chassis have disc-clutches and four-speed gear-boxes of the standard Fiat pattern. As these parts, however, have been very fully illustrated and described in THE AUTOMOTOR JOURNAL of July 22nd last, it will not be necessary to again refer in detail to them now.

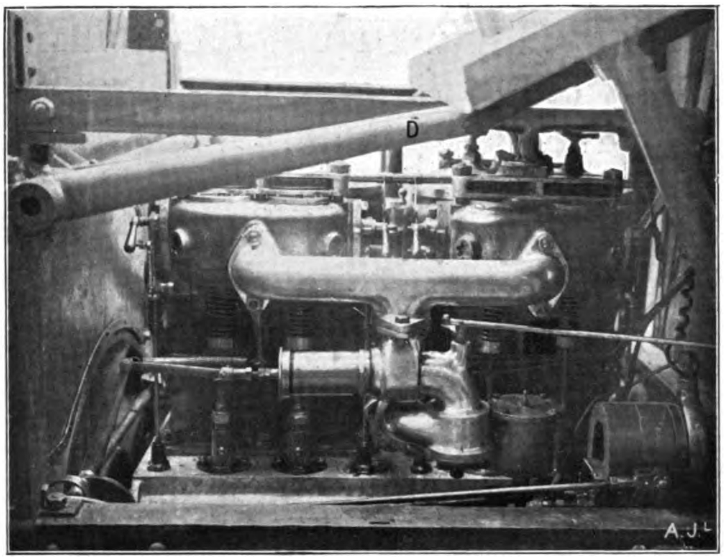

Fig. 6.—The Fiat 'Bus Chassis. View of the 24-h.p. Engine, showing the Carburettor and Low-Tension Magneto. The position of the Lever, D, for the Brake Pedal is prominent in this view.

For the 16-h.p. model a pressed steel frame is provided, and it resembles in general appearance —as will be evident from Fig. 8—a touring chassis; in fact, this model is principally intended for use as a station omnibus, and it is, of course, eminently suitable also for a shooting brake, as it has a very smart appearance. The 24-h.p. model, on the other hand, has a rolled steel frame of very substantial proportions, and it is capable of acting either with a platform, as a four-ton lurry or, with a double-decked body, as an omnibus.

The heavier chassis—which is illustrated in Figs. 1 to 7—is naturally of very large overall dimensions, and in order to reduce the wheel-base, which now measures 10 ft. 2 ins., the front axle has been set back behind the engine. Some economy of platform area, too, has been obtained by placing the driver's seat high up, so that the floor-boards below it form the top of the bonnet. Neither is the engine rendered really inaccessible by this arrangement, for one of the boards is removable, and the entire sides of the bonnet can also be readily detached. Our photographs in Figs. 6 and 7 were taken with the engine *in situ*, so they give some idea of how much of it can be easily got at from outside.

Of the four-cylinder type, the engine has a bore and stroke measuring 125 mm. and 150 mm. respectively, and it is capable of developing about 40-h.p. The cylinders are cast in pairs, and have the inlet and exhaust valves arranged symmetrically on either side, with the low-tension igniters set sideways into the inlet valve chambers. Inspection covers are provided above all the valves, and are held in place by yokes to facilitate their quick removal. In front lie the gear wheels which

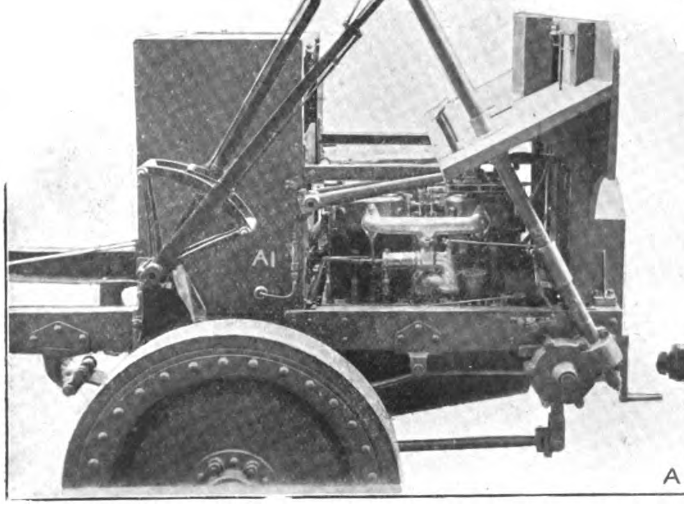

Fig. 4.—The Fiat 'Bus Chassis. Side view of the front portion of the Chassis, showing the position of the Engine and the arrangement of the Steering Gear. Near the change-speed lever quadrant is the little valve, A^1, which is interconnected with the brake-pedal for the purpose of controlling the water supply to the brake drums.

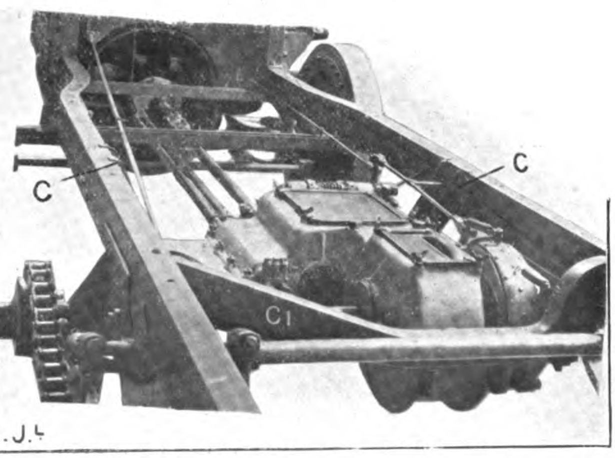

Fig. 5.—The Fiat 'Bus Chassis. View showing the arrangement of the Gear-box, which has a three-point suspension, being carried in front by independent brackets, C, attached to the Frame, and behind by the specially-bent transverse member, C^1.

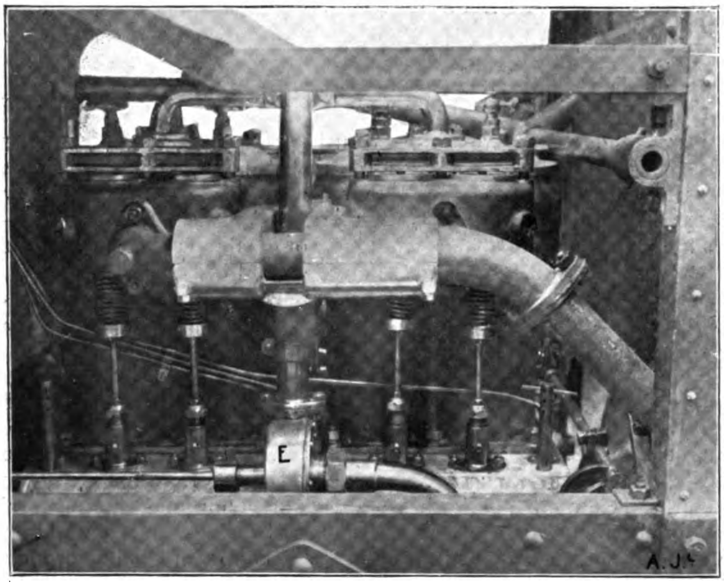

Fig. 7.—The Fiat 'Bus Chassis. View of the Engine from the left, showing the Circulating Pump, E.

drive the cam-shafts, and on one side of the engine is the low-tension magneto, while on the other is the circulating pump, each being driven by an independent spur-wheel in mesh with that on the end of the cam-shaft adjacent to it. In order to bring the pump, E, into a more accessible position than usual, and to simplify the pipe connections, it is mounted in a very prominent position on the crank-chamber. In Fig. 7 it will be noticed how conveniently the pump is situated both for inspection and also for eliminating awkward bends in the water pipes.

In front is the usual honeycomb radiator, and above this rests the dashboard which carries the Fiat mechanical lubricator. The steering-column, which has a convenient rake, passes to one side of the bonnet, and the worm and sector gear at its lower end, is attached to the side of the frame. From this the connecting-rod passes backwards to the steering-knuckles, which are coupled by a tie-rod lying behind the axle.

Both change-speed and brake levers are mounted on a bracket to the right of the driver, who controls the engine by a throttle lever situated above the steering wheel; the low-tension magneto ignition is regulated automatically by the engine, as it is on all Fiat cars. The clutch-pedal is interconnected with the brake-pedal, but the side-brakes, which are of the internal expanding type, are quite independent. Two compensated brakes on the second motion and differential shafts respectively are operated by a pedal, and their drums are water cooled from a tank, A, situated close to the petrol tank, B, which is under the driver's seat. This water supply is regulated by a valve, A1, Fig. 4, which is interconnected with the foot pedal.

Suspension of the frame has received careful attention, and the springs are of considerable length. On the chassis, illustrated in Figs. 2 to 7, pressed steel wheels with iron tyres are fitted, it will be noticed, but for 'bus work the ordinary rubber-tyred wheels would, of course, replace them.

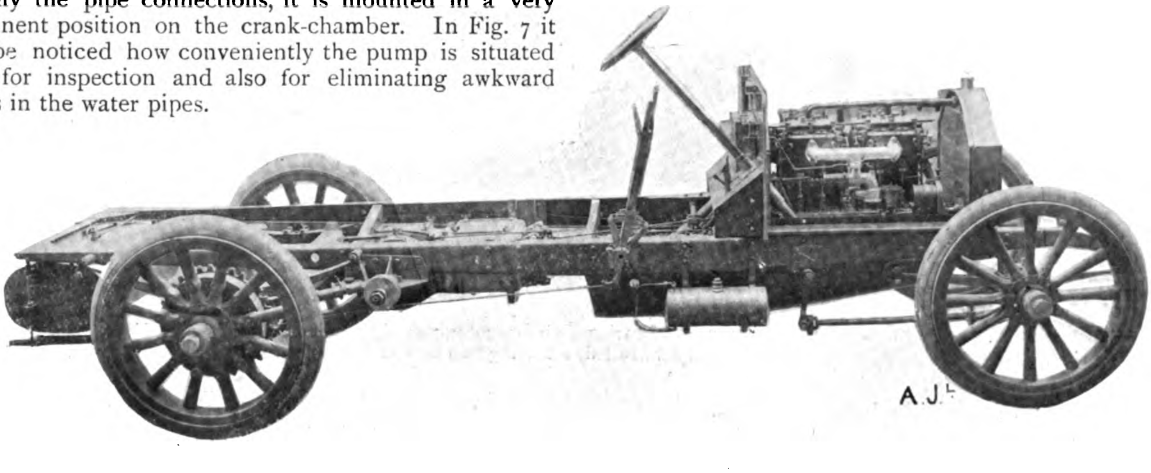

Fig. 8.—View of the 16-h.p. Fiat 'Bus Chassis, which has a pressed-steel frame and is constructed on practically the same lines as the ordinary Touring Model.

To train Car Drivers.

THE dearth of competent drivers of British birth is emphasised by a recent incident. The Motor Union asked the London County Council whether they would be prepared to support financially some comprehensive scheme to provide training for motor car drivers. It appears that the only London County Council institution in which such instruction is provided is that of Battersea. Nevertheless the Education Committee has, we understand, adopted the view that the required training would be more economically and efficiently provided by utilising some of the London polytechnics and technical institutes.

Motor Houseboats.

A HOUSEBOAT on wheels propelled by motor power has always appealed to popular imagination and has already inspired the attempt to form an institution for their use under the title of "Home Car Club." A vehicle of this kind which presents some of the features of an enlarged touring car is being utilised in Paris. It is sufficiently mobile to take a large party to the theatre and jog leisurely home with them again. Speed is a secondary consideration, as the size and equipment of the vehicle are such that whenever its occupants feel inclined they can stop on the roadside or a suitable field and pass the night in all comfort, resuming their journey next day—or next week.

THE HOFFMANN BALL-BEARINGS FOR MOTOR CARS.—PART I.

ONLY a year ago manufacturers and others held very diverse opinions concerning the merits or demerits of ball-bearings in motor car design, and it was by no means the usual thing for cars in general to be fitted with them. Nowadays, however, the automobile engineer has been fully convinced of the great advantages that are derivable from their employment, with the result that there are to-day comparatively few cars on the market having plain bearings for the road-wheels or for any of the revolving shafts in the transmission mechanism. He has, during the past year or two, in fact, been able to obtain ball-bearings that are thoroughly reliable for supporting a considerable amount of weight and are able to withstand really hard work continuously, whereas formerly mechanical defects of design and construction rendered unsatisfactory such ball-bearings as were then available. It is not that motor car designers have not appreciated the possibilities of such bearings for a considerable period, for it has always been freely admitted that they offer less friction to *starting* than do ordinary bearings, that they suffer least from neglect in lubrication, and effect a saving of power.

It is not at all surprising, however, that very grave difficulties should have been encountered in producing thoroughly satisfactory ball-bearings, because so very much depends upon precision of workmanship and hardness of material, to say nothing of the further question of actual design that is of such vital importance to obtain the best results. And it is obvious, too, that any such bearings must be turned out in extremely large quantities if they are to be sold at anything but a prohibitive price. Early failures, or only partial successes, are only what might reasonably have been expected until an enormous amount of experimental work had been conducted, and much invaluable data obtained. While, even after that, a considerable amount of time and capital obviously had to be expended in the equipment of the necessary works, with costly special plant for accurate manufacture in large quantities. Even the manufacture of perfectly true, absolutely interchangeable, and equally hardened, steel balls, is in itself no easy matter, and yet the balls themselves are usually regarded as being the simplest portion of a complete bearing.

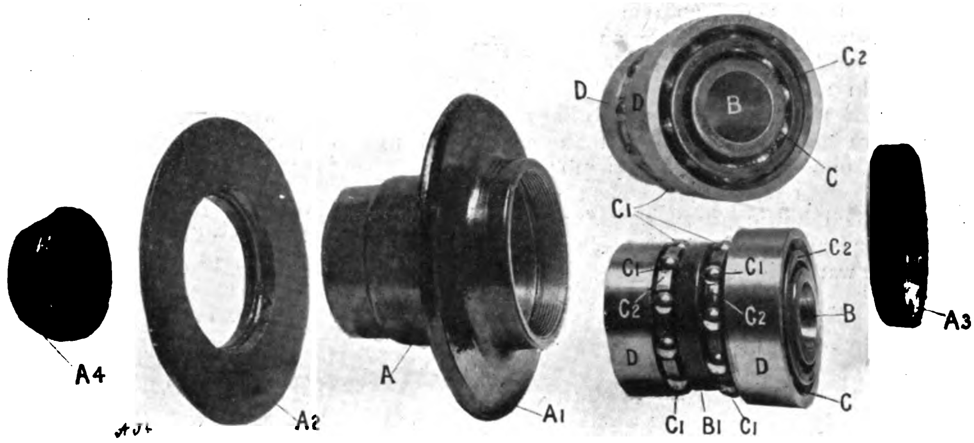

FIG. 1.—The Hoffmann Ball-Bearing Hub for motor cars of the chain-driven type. Views of the chief component parts dismantled, including two different views of the ball-bearing proper.

It is now some little time since development in this direction enabled manufacturers to supply reliable ball-bearings for such comparatively light work as bicycles, and the result has been that no builder of such machines ever thinks of using any other form of bearing now. But the conditions under which such bearings have to work become vastly more severe when used on machinery of heavier kinds, so that any slight inaccuracies of construction—or any faultiness of design—are sure to lead to trouble; and trouble with a ball-bearing is serious.

Of recent years, an enormous amount of progress has been made by the ever growing number of firms who have devoted their energies to the task of solving this difficult problem, with the result that ball-bearings of large size are now being made for high-speed machinery of all kinds, and for the wheels—as well as the transmission mechanism—of automobiles. Prominent amongst these concerns is the Hoffmann Manufacturing Company, who have spent an enormous amount of money in evolving satisfactory bearings, and have built and equipped an extremely large factory at Chelmsford for this express purpose. They have, during the past two or three years, been quietly conducting exhaustive experiments with special bearings of the larger sizes, and have for some time acquired an invaluable reputation—both in this country and abroad—for the exceptionally perfect balls which their special methods of manufacture have enabled them to turn out—balls which have done much to improve the bicycle of to-day, and have, moreover, been of immense value to not a few makers of motor cars.

The works—although in England, and although equipped with English-built machinery(!)—are laid out and conducted upon what are popularly supposed to be exclusively American up-to-date lines, and are certainly one of the best organised factories that it has been our pleasure to visit. The special machinery installed turns out automatically the rough balls from rods of steel, the tools in the lathes machining them all over during this single operation. Subsequently they pass through various operations—which are naturally of the nature of trade secrets—and finally the balls emerge polished and finished, so absolutely spherical and true to size that they can be guaranteed by the company to be within $\frac{1}{10000}$ of an inch of standard measurement. One of the most important of the processes is that which ensures equality of the tempering during the operation of hardening.

Until a year ago, the only standard types of complete bearings that the Hoffmann Company were able to supply for motor car work were the thrust-bearings, with which they have been so successful for a variety of machinery. Since then, however, they have introduced several different patterns to suit each and every part of the entire transmission mechanism, and have, in particular, given special attention to the design of ball-bearing hubs for the road wheels. Each of these types is made in several sizes, so that the company can meet the requirements of those building cars of any kind.

It is to the hubs that we first propose to devote our attention, before passing on to the other forms of Hoffmann bearings that are equally applicable for automobile work, and of these we shall in the first place describe the construction of that type which is specially intended for vehicles having stationary axles—the rear wheels being driven by side chains. In the main, the hubs for cars having "live" axles are also of similar design, so that those hubs will be more readily understood afterwards, and the difference between the two distinct types—which the company are making—will be more easily explained then. In all these hubs, four rows of balls are employed, two of which take the weight of the car and the other two take the thrust.

One of their most interesting features is that the ball-bearing proper can be completely removed, and that it can then be even roughly handled without fear of the balls dropping out. By an extremely neat bit of designing—coupled with great accuracy of workmanship—it can, however, be taken to pieces without difficulty, and, with equal ease, be put together again. Other essential characteristics are the cages that are employed for preventing the balls from running in contact with one another, and the way in which the races are arranged so as to give but two contact points to each ball, of which features we shall have more to say later, when dealing with the general design of the Hoffmann bearings. The shape of the races, in combination with the cages, is such as to hold all the balls in place, and it is particularly important to recognise the fact that no adjustments whatever are provided, since it is unnecessary to make any provision for taking up wear.

The "Fixed" Axle Type of Hub.

Of the accompanying illustrations, which show the ingenious construction adopted, Figs. 1, 2 and 3 refer to the stationary axle type of hub. In Fig. 1, the axle-cap, A^4, has been taken off the main housing, A, and the flange, A^2—between which and the flange, A^1, the spokes are bolted—has also been slipped off, while, at the other end, the threaded collar, A^3, has been unscrewed, and the complete ball-bearing forced out. The ball-bearing proper is, in this illustration, shown from two different points of view.

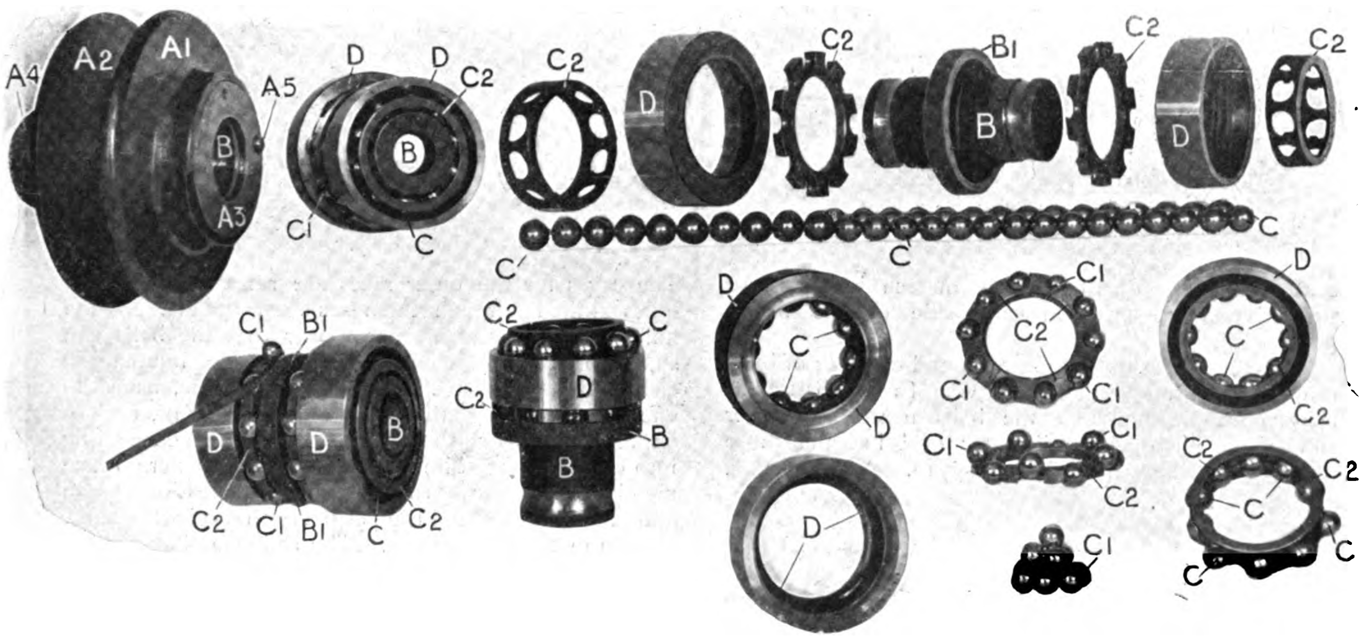

FIG. 2.—The Hoffmann Ball-Bearing Hub. Views of the complete hub of the ball-bearing proper, and of all the component parts separately; also two views showing the method of removing the balls, and other views demonstrating the design of the cages in relationship to the balls.

In Fig. 2, the complete hub is shown to the left at the top of the illustration, and, in addition, all the component parts of the ball-bearing proper are shown in such a way as to render their shapes and positions clear, while the two views in the left hand bottom corner serve to demonstrate the manner in which the bearing itself can be taken to pieces when required.

The upper half of Fig. 3 is a longitudinal cross-section through the entire hub, and shows the tapered end of the stationary axle, E, in place inside it. The lower half of the illustration is in elevation. By comparing this drawing with Figs. 1 and 2, the entire construction can be followed.

Referring to these illustrations, the central portion, or cone, B, of the ball-bearing has a tapered hole bored through it, and it is this part that fits over the end of the stationary axle, E, to which it is held rigidly in place by the locked nut, E^1; the complete hub with the wheel can at any time be removed from the axle by taking off this nut. The cone, B, which is made of the finest hardened steel, has the four ball races ground upon it for the four sets of balls. The races near each end take the form of grooves that are cut down into the cylindrical face, whilst those near the centre—for the thrust portion of the bearing—are slightly concave faces in each side of the flange portion, B^1.

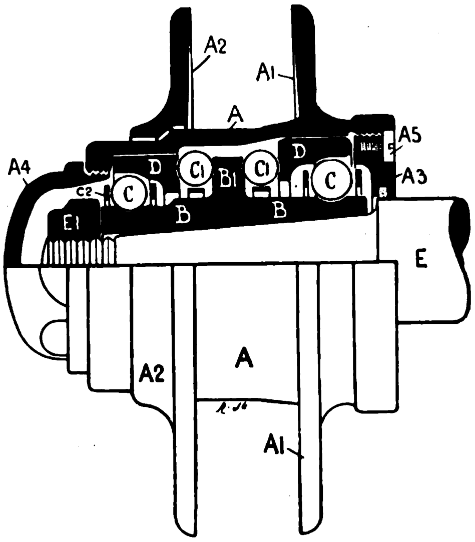

FIG. 3.—The Hoffmann Ball-Bearing Hub for cars of the chain-driven type. Half longitudinal cross-section and half elevation.

There are ten balls to each race, and each set of balls is arranged in a retaining cage, C^2. In the particular bearing examined by us, the balls nearest the inner end of the hub have a diameter of $\frac{1}{2}$ in., and those forming the three other sets are $\frac{7}{16}$ in. All the cages, C^2, which are of phosphor bronze, are of very special construction. Primarily they play the extremely important rôle of preventing the balls from rubbing against one another, and thus they save the unnecessary friction that would otherwise be set up between the rubbing faces, which run in opposite directions to one another.

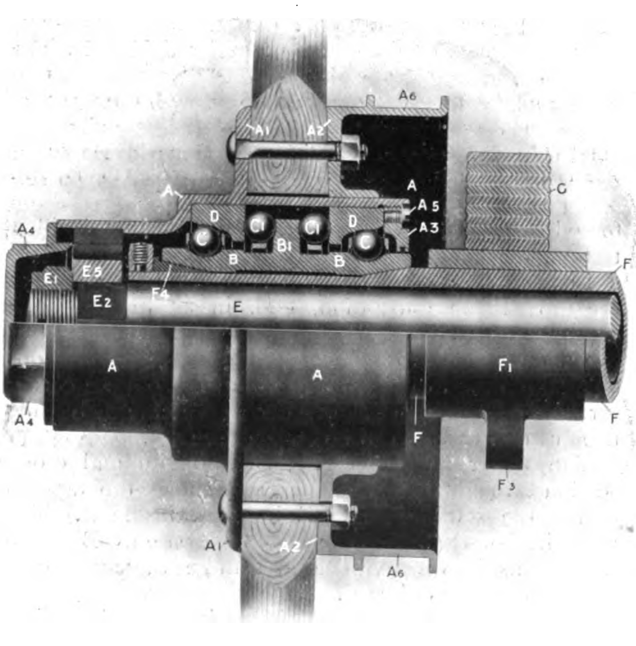

FIG. 4.—The Hoffmann Ball-Bearing Hub for cars of the live-axle type, in which the weight of the vehicle is *not* taken by the "live" shafts. In the upper half of the illustration the hub is cut away to show the internal construction.

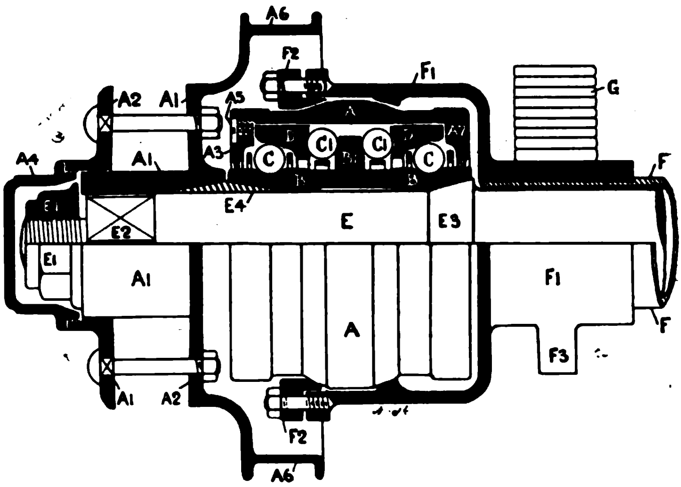

FIG. 5.—The Hoffmann Ball-Bearing Hub for cars of the live-axle type, in which the weight of the vehicle is taken by the "live" shafts. The upper half is a true longitudinal cross-section through the entire hub, and in the lower half the external portions only are shown sectionally.

The cages for the outer races are rings with tapering holes drilled through them—as seen in Fig. 2.—the holes being tapered in such a way that the balls can slip into place in them from the outside, but cannot enter from the inside. The balls, therefore, have the effect of centring the cages about the shaft, and of entirely supporting them so as to prevent their coming into contact either with the cone, B, or the external race members, D. The cages for the inner races are disc-shaped, and are slotted around the periphery to receive the balls, as seen in the illustrations. The slots may be regarded as tapering holes that are drilled through the discs so near to the periphery that they cut right through it. Each alternate slot is tapered in the opposite direction, so that half of the balls have to be slipped in from the one side and the other half from the other side—as rendered evident in Fig. 2. By this construction, the balls centre the cage about the shaft, and also cause it to run true with the ball races, without its touching either the central portion, B, or the external shells, D.

The shape of the external members or shells, D, of the ball-bearing is clearly shown in the illustrations, where it will be noticed that these shells are turned cylindrical outside, are open in front, and have the races turned on the inside, and on the back faces, for the "load-carrying" and the "thrust" bearings, respectively. Externally, they are turned to an absolutely true fit to suit corresponding faces inside the hub portion, A, into which the ball-bearing proper is introduced as a complete unit from the inner side. When slipped in in this way, the smaller shell comes up against a shoulder—as seen in Fig. 3—and the larger shell is forced in to precisely the correct distance away from it by the collar, A^3, that is afterwards screwed into place. It will be noticed that the collar, A^3, in reality forms an adjustment for the ball-races, but it is made once and for all in the factory, and the small screw, A^6, that locks the collar, is so arranged that it can only be introduced when opposite a single slot, cut for it in the hub, A; there is therefore no chance that the inexperienced will be misled into attempting to adjust the bearing.

The inner face of the shells, D, is curved in the immediate vicinity of the balls, C, and the mouth is cut away at a sharp angle to allow the bearings to be taken to pieces—in the manner that will be described presently. The face at the back of the shells is, for the most part, flat, but the actual races themselves are slightly curved. The shells, D, do not, of course, touch the cone portion, B.

From what has already been said, the actual construction of the ball-bearing proper will have been made quite clear, but it is quite another matter to see how it is possible to put it together or to take it apart again. It is obvious that, when the races are pressing up against the balls, C^1, none of these balls could be removed—even if their cages were not there—and it is also clear that the balls, C^1, must be removed before it is possible to take out the outer balls, C. It is, as a matter of fact, however, extremely easy to take the bearing to pieces, although there is no chance of its *falling* to pieces after it has been removed from the hub. This is provided for in the design, but has only been rendered possible by the extremely high-class and accurate workmanship employed.

The actual operation of taking the bearing to pieces is rendered clear by the two views to the left in the lower part of Fig. 2. The outer ball-races are so shaped as to allow a certain amount of end play of the shells, D, and this end play is just sufficient to permit one of the balls, C^1, at a time to be forced up outwardly, between the races and past the cage, by inserting some such instrument as a knife beneath it. The ball neither drops out, nor, on the other hand, is there any chance of damaging the bearing in forcing it out; it just jumps out, and acts exactly as though it had been held between two powerful springs; similarly, when replaced, it flies in with a click. Half the balls, C^1, in each race are, of course, taken out from the one side of the cage, and the other half from the other side. The internal shape of the shells, D, is such that, after having removed the balls, C^1, each set of balls, C, together with its cage, can pass out over the end of the cone, provided that the shell, D, is, at the same time, allowed to slip back in the opposite direction. There is then just room for the balls—as they are wedged outwardly through the holes in the cage—to clear the mouth of the shell, in the way they are doing in our illustration.

It will be understood that the hub, A, is constructed to suit artillery wheels of the ordinary type, the spokes being secured to it by bolts that pass through the fixed flange, A^1, and the detachable flange, A^2. It is also made to take wire spokes, in which case it is provided with two fixed flanges for that purpose. The entire bearing is rendered dustproof by the usual screwed cap, A^4, on the outside, and by a felt washer fitted into the groove seen in the collar, A^3, on the inside.

(*To be continued.*)

MELBOURNE-SYDNEY RELIABILITY TRIALS.

AERONAUTICS.

A Prize for British Aeronauts.

WITH a view doubtless of encouraging experiment in aeroplane flight in this country, and in the hope that Great Britain, if not first in the field, may come in a good second or third, Sir David Salomons, Bart., who is a life member of the Aero Club, has offered a valuable prize to that body for the first mechanically-propelled aeroplane which flies a certain distance successfully through the air (we presume carrying an aeronaut), and returns to the point of departure. So far, British experimenters have been rather conspicuous for their omission to attempt the conquest of the atmosphere on the aeroplane principle. Of course, there were the experiments many years ago of Sir Hiram Maxim near Wembley Park, which adequately demonstrated—though the fact of the demonstrations has been pretty generally neglected since—that an aeroplane, driven by a powerful motor operating suitable propellers, was well able to lift itself, motor, and a load, and there have been. quite recently we believe, some experiments in the Isle of Wight, carried out by Dr. Barton and Mr. F. L. Rawson. In addition to these, there were what we may call the classic experiments of Pilcher, with a multi-cellular aeroplane or gliding machine that resulted in his premature death. These few instances sum up practically the whole (with the exception of experiments with mere models) of serious British contribution to the solution of the problem of flight on the heavier-than-air principle. It is rather strange that this should be so, and it is possible that British experimenters may be encouraged if they consider in some detail the history of the Wright Brothers' experiments.

The Wisest Course to Follow.

WHATEVER view may be held as regards the exact distances *they* have flown, the precise speeds attained, or the number of flights they have accomplished, there can be but little doubt that they have accomplished extended free flight with a motor-driven aeroplane. It is instructive, therefore, to call to mind the gradual steps of their progress. Their first experiments, carried on for several years, consisted entirely of gliding with a machine which might be described as a Chanute aeroplane, that is, a double-decked arrangement with curved surfaces, to which they added their special inventions of a forward rudder and a vertical tail. They themselves attributed (and there is little doubt that they were correct in doing so) the success of the earlier experiments, and the mastery they obtained, of "gliding" to the favourable characteristics of the district in which they experimented—the Devilkill Hills, on the coast of North Carolina, which are in fact big sand hills overgrown with grass. On these hills for many months in the year a regular easterly wind blows off the Atlantic, often averaging 20 miles an hour in speed for weeks together. They were able to obtain almost any slope on these hills that they required. If they came down unexpectedly on the soft surface of sand and rank grass no injury was done. and they could rely for long periods together on obtaining just the sort of wind they wanted.

Aeroplane Manipulation.

THERE are some grounds for believing that the actual manipulation of a motor-driven aeroplane in the air, so far from being more difficult than managing a gliding machine, is, as a matter of fact, rather easier, but we seriously doubt whether anyone will ever learn to accomplish it unless instructed by someone who has learned the art before him, or unless he has previously learned to "glide," although the mere fact that flight has now been proved possible makes an enormous amount of difference. If no one had ever seen a man ride a bicycle the possibility of maintaining oneself in equilibrium on two wheels arranged tandem would be frankly and sincerely doubted, and first experiments would convince anybody in a short time that it was impossible, *unless they knew it could be done.* Knowing it can be done, people learn with comparative readiness, and now that it has been done, there will probably be more success in manipulating aeroplanes in the air.

A Suitable Spot for Experiments.

ALL the same, the most promising line of experiment to adopt is that which has been proved to be successful, *i.e.*, to begin with gliding. Now it so happens that there is a district in the south of England, which if not quite as ideal for the purpose as the Devilkill Hills, presents many of the very same advantages. We refer to the chalk downs of Sussex, particularly where they sink towards the strip of alluvial and tertiary deposits that begin eastwards near Shoreham and gradually widen out towards Chichester and Selsey Bill. Here rounded hills sloping in nearly every direction and with almost every degree of inclination to the horizontal can be found in abundance. They are covered with soft and springy turf, and are almost entirely treeless, while for many weeks in ths summer, often enough, a steady south-west wind blows off the sea. This is a spot that nature would seem to have designed for the British experimenter to learn to glide. So many of the hills have but a moderate slope that the same district would probably provide plenty of sites on which subsequent experiments with motor-driven machines could also be attempted. If, however, for these later developments a flatter *terrain* were desired, the very spot for the purpose is Salisbury Plain. As the Sussex Downs are nice and secluded, and one can often walk for miles without encountering other specimens of *homo sapiens* than a solitary shepherd, it would seem to be the ideal spot for experiments of the kind.

An Opening for Sportsmen.

WHY sport-loving athletes have not taken it up has always been something of a mystery. A gliding machine is cheap to build; only pluck and address are needed for its manipulation. Conquest of the air by its means should, one would think, prove at least as amusing, certainly more exciting and worth accomplishing, than proficiency say at golf, and an intelligent and athletic experimenter would probably accomplish all the Wright Brothers have effected in less time than many people have devoted during the past few years to the more or less successful cultivation of the Scottish national game. Of course, the sport is not unaccompanied by danger. As Mr. Chanute said, on one of the few occasions on which he spoke publicly in this country, there *is* danger, though with the pluck to adopt the horizontal position which the Wrights adopted, and which he modestly admitted he never was himself sufficiently adventurous to attempt in the thousand successful glides which stand to his credit, it is reduced to a minimum. But a spice of danger is what the true sportsman loves, and nothing great is ever accomplished without perseverance, resource, and, often enough, risk.

More Wright Rumours.

The Wright question still continues to attract a good deal of attention among our contemporaries, particularly in France, though little further light has been thrown upon the situation. That is not to be wondered at, as it is admitted that the Wright Brothers have finished their experiments for the season, and dismantled their machine. A statement has appeared on the authority of the *New York Herald* to the effect that Mr. Arnold Fordyce is negotiating with the Wright Brothers for the disclosure of their invention, including presumably whatever patent or other rights they may possess, and that amongst the conditions of the agreement which he has made, is that the Wright Brothers are to give demonstrations with their flying machine within three months' time, and that they undertake to cover 50 kilometres from the starting point without touching or communication with the ground (and returning presumably to the starting-place) within an hour. Mr. Fordyce declared that after the agreement had been concluded, the Wright Brothers showed him photographs of their machine in full flight, which thoroughly astonished him. We hope this is all a correct statement of facts, as, should it be so, the result will probably be that the Wright Brothers will have to come across to France to demonstrate their invention, and when they are there, they might as well condescend to pick up the trifle of £2,000 constituting the Deutsch-Archdeacon Prize of the French Aero Club. This they should be able to do without difficulty, as all that is required is to start from a given point, sail round a stake, or other obstacle such as the Eiffel Tower, half a kilometre distant, and return to the point from which they set out. It is much easier to get to Paris than to Dayton, Ohio, and if the event is announced for any particular day, there will probably be a considerable emigration of aeronauts and others interested in the question from the British Islands to the city of the Seine to witness its accomplishment.

One-Sided Criticism.

In the meantime there has been a good deal of acrid criticism of the accounts which have been published of the Wright Brothers' performances, in journals across the Channel which do not happen to have sent representatives to investigate the question on the spot. These rather captious critics seem to forget that the question as to whether the Wright Brothers actually flew 2 miles or 20 is relatively unimportant, for if they flew 2 miles, it is certainly only a matter of time whether they will be able to fly 20 or 200, and a lot of fuss has been made about the apparent impossibility of accomplishing a speed of 100 kiloms. an hour with a motor developing only 15-h.p. As a matter of fact, the Wrights distinctly stated that their motor developed 24-h.p., and though Mr. Weaver in his report stated its power to be 12 to 15-h.p., he is evidently under some misapprehension, that having been the power of the motor with which the Wrights performed their first free flight in 1903. Nobody has ever stated, and they have never claimed, to have accomplished a speed of 100 kiloms. an hour. Sixty kiloms. was their maximum except at the end of their experiments, when they just reached 40 miles an hour. To set up a cardboard lion on the stage and knock it down yourself with a club is a trick as old as the days of Nero, but it is not treating the question either fairly or ingenuously to take one account which minimises the power of the motor employed and another which, without any authority whatever, nearly doubles the actual speed attained, and from the two combined to attempt a *reductio ad absurdum* of the main contention.

The French Army secures the Lebaudy Airship.

Everyone who has followed the splendid record of the Lebaudy airship, more particularly the successful and reliable manner in which it carried out its military evolutions under the supervision of the French military staff at Chalons and Toul, will be pleased to learn that the French Government has taken over the great machine, and that it has now definitely passed into the military service of its country. The airship is now ensconced in the fortified camp surrounding Toul. It is understood to be ready to take the air as soon as re-inflated, and reconnoitre any suspicious movements in the neighbourhood or, presumably, on the other side of the Rhine at a moment's notice. With the most praiseworthy patriotism and singular generosity, the owners of the great airship, Messrs. Paul and Pierre Lebaudy, have in this way dedicated it to the service of the nation. Considering the enormous sums that they have spent on its perfectation, they are certainly showing an example of the highest devotion to the interests of their country.

It is of interest to learn that Messrs. Lebaudy's works at Moisson, where the present airship was built "from truck to keel," are already busy with the manufacture of another airship, the Lebaudy of 1906.

MELBOURNE-SYDNEY RELIABILITY TRIALS.—Finishing up the run of 1,276 miles at Coburg Control near Melbourne. S. Day on his 8-h.p. De Dion passing the finishing point.

THE SHOW QUESTION.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In your issue of the 23rd ult., Mr. Charles Newton refers in a letter to the British Empire Motor Trades Alliance, Limited.

As a member of the above Alliance, I should like to reply to some of his questions.

He asks why the Alliance did not arrange for better positions for the British manufacturer at the Automobile Exhibition than their foreign competitors.

Until quite recently, the agents have formed a more powerful section of the Society of Motor Manufacturers than the British manufacturers. The agents may be interested in some British make, but until now their greater interest has been in foreign cars, so that the British manufacturers were not in a position to insist on a preference.

The British manufacturers are now becoming strong enough to insist on their rights, and if a few more people look at the question in the same way as Mr. Newton does, there is no doubt they will get them at an early date.

Yours faithfully,
J. I. THORNYCROFT.

Chiswick, Jan. 3rd.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I do not think that Mr. Chas. Newton can be connected with the motor trade, or he would not even suggest a Show for all-British motor vehicles only.

It would be the most troublesome matter imaginable to the whole industry. The Olympia Show has already entered into severe competition with the Paris one, with the result that the Continental makers—having found that the holding of the Olympia Show before Paris resulted in a very serious loss of business to the firms showing only at the latter Show—now advocate the holding of the Paris Show of 1906 in October, and it seems likely that the Olympia may also be advanced again so as to still be in front of the Paris one.

If in addition to the above competition there is also rivalry between two English Shows, both trying to be the first in the field, we may arrive at the time when the Show of, say, 1909 models, will be held in November, 1907.

There is another, and, I think, more serious point of view in the interest of British manufacturers. If British-made cars are as good as, or better than, the foreign, why take steps to prevent the foreigner competing on even terms? If on his merits the British manufacturer ousts the foreigner, his victory will be overwhelming, but, on the other hand, if it is through show or any other preferential juggling, there will be many well-informed motorists who will retain opinions of their own.

Now to speak in the interests of the buyers (public). Is their patriotism so strong that motives of self interest do not intrude, and is it not the best value, irrespective of country of origin, that is the main quest? After all, are not the interests of the trade best served by free and healthy competition?

I cannot think that a restricted Show would be welcomed either by the motor trade in general or the private users of motor vehicles.

Yours truly,
ERNEST H. ARNOTT.

Teddington, Jan. 3rd.

6 CYLINDERS v. 4 CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I for one among British manufacturers who aspire to be among those at the top, and to see everything, where possible, produced in this country, and for its benefit, have the greatest possible pleasure in accepting Mr. S. F. Edge's sporting and unique offer to have a 6-cylinder car placed at my disposal for a day or so, I, of course, insuring it against all risks while in my possession.

I do not wish to be outdone, even by Mr. Edge, in breadth of mind and the desire to help my fellow home manufacturer, and if Mr. Edge, or any of his able staff, care to have a 6-cylinder Ariel-Simplex car placed at their disposal for a like period, it will give me the greatest possible pleasure to reciprocate the laudable desire to place the home industry on a firm and lasting basis, which must underlie your able and frequent correspondent's letter.

Yours faithfully,
CHAS. SANGSTER.

Ariel Motor Company.
Jan. 4th, 1906.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Most of your readers must, I feel sure, be getting rather tired of the aimless wanderings of your interested correspondents, who are doubtless endeavouring to grind their own axes to each other's discomfiture. As a mere struggling dealer in both four and 6-cylinder cars, I trust I may be allowed to air my views without bias, as it makes no difference to me which particular type I sell, except that the profit on cars fitted with six cylinders is rather in excess of those fitted with four. After carefully considering the claims advanced for the 6-cylinder engine, I cannot see that the advantages outweigh the increased liability to break down, and it must be admitted that on a 6-cylinder engine there are 50 per cent. more working parts to give trouble than on a 4-cylinder, and now that my old friend Charlie Rolls has produced a car fitted with sixteen valves, I look forward with some dismay to the conversation that will take place at a way-side inn between the chauffeur and his master, which will be something as follows:—

Master: "John, what is the matter with the engine?"

Chauffeur: "I am afraid it is the twenty-ninth valve which has stuck up."

This is what will happen in 1907 when we see 16-cylinder engines.

Yours faithfully,
J. E. HUTTON.

Jan. 5th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR, Your correspondent—Mr. Gladstone Colebrook—asks me for some information. I will answer it, and I hope the answer will be satisfactory to him, and that he will take the trouble and fairness to compare the measurements I give him, with 40-h.p. 4-cylinder cars, and I think he will find that the measurements of the 6-cylinder Napier are very excellent.

The 40-h.p. 6-cylinder Napier wheel-base is 9 feet 8 inches. The three pairs of cylinders take up 33 inches.

His suggestion that a 6-cylinder engine is one-third longer than a 4-cylinder one is obviously inaccurate, as I assume he wishes the comparison to be made between engines of similar horse-power. For example, four 5-inch cylinders would give say 40-h.p., six 4-inch cylinders would give at least equal horse-power. Therefore, the difference in length, so far as the cylinders are concerned, need only be 4 inches. Of course there is not the slightest necessity to get the same horse-power with the 6-cylinder engine, for it to be one-third longer than a four. Then, in regard to the proper distribution of weight, the distance from the dashboard to the centre of the front axle on the 40-h.p 6-cylinder Napier is 36 inches.

I think he will find that this is about the usual accepted position for the front axle on a similar h.p. car. It is quite useless him referring to the 6-cylinder foreign car which was shown at Olympia. Surely I must not be blamed because a foreign manufacturer has been unable to properly design a 6-cylinder car, and will your correspondent, after fairly considering the measurements I have given, make a fair and honourable retraction of his mis-statements?

Yours truly,
S. F. EDGE.

January 6th, 1906.

STICK TO THE SUBJECT—AND DROP PERSONALITIES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I notice in last week's issue of your paper a letter from Mr. Jarrott and also one from Mr. Edge. Now, the letters which have been written by these two gentlemen on the subject of 4 and 6-cylinder engines have been very interesting, but I regret very much to see that this last week they have taken a different tone altogether. They are what I may call personal attacks upon one another, and this state of things is much to be deplored, as two such good friends, both good sportsmen, should not allow personal feelings to come into their letters. By all means, Mr. Edge, write all you can in favour of the 6-cylinder engine, and if you, Mr. Jarrott, will champion the 4-cylinder, we shall all be much obliged to you, and shall look each week for the different arguments you can bring forward, but do not get on to politics or personal feelings, for the sake of your old association. Remember, I am only one of the buying and trading public, but still at the same time I know you both very well.

Yours faithfully,
"THE TRAMP."

BRITISH *versus* FOREIGN CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In reference to the vexed question of British and foreign manufacture of automobiles, I have read the communications in THE AUTOMOTOR JOURNAL, and confirm my numerous public utterances to the effect that, personally, I am a firm believer in the protective tariff—say, 15 per cent. on all imported cars. This would secure to us Englighmen the standard asset of our own country's trade, which policy, bearing in mind that we are the largest buyers of automobiles, would do wonders for the British industry. On the other hand, I do not permit sentiment to enter into my business affairs, and, bearing in mind that no such tariff is in existence, and there still exists a grave doubt as to whether it ever will exist, I fail to see why, in the event of a demand arising for foreign manufactured cars, we should fail to supply them.

The importation of these vehicles is distinctly a profitable business—in fact, better for the importer (who is usually a Britisher) than the foreign manufacturer. The numerous high-class cars made in France, Germany, and Italy, should obviously receive their due share of appreciation at the hands of the British public, as do all high-class manufactures, independent of the country in which they are produced, and justly so. These machines have secured sound reputations, and when the demand is created, why should we hesitate to do the business?

In my mind an inference may be drawn from Mr. Jarrott's letter, to the effect that French cars are superior to those manufactured in this country, and although this may have been the case until recently, I certainly think that this is not so to-day. We have several firms in Great Britain producing cars in all respects equal to the French makers, and, in fact, second to none in the world. I am able to cite an instance which proves that foreign goods are not finding better favour, at any rate in the commercial line, than British-made chassis. For instance, my firm is importing heavy chassis from Germany; on the other hand, we have purchased the patents, and are manufacturing the same vehicle in this country, and although until quite recently we have been willing to supply British or German cars to order, our order sheet to-day for the British cars represents upwards of £400,000, whereas that for the foreign cars approximates only £45,000, and buyers are now, after mature experience of the British cars, specifying that their goods are to be British built. This is a significant fact which clearly shows the importance of adopting a practice whereby a correct model is employed irrespective of its original source. While I have no desire to say anything which may depreciate the importance and desire for original productions, I firmly believe the great drawback to more rapid progress in satisfactory car manufacturing in Great Britain is largely due to the fact that much time has been wasted in carrying out experiments with new schemes without previously fortifying our knowledge by ascertaining what others who possess greater experience are doing before we start to prepare drawings.

There are several British firms known to me, who until recently have been in a fairly large way of business, and their productions, I must admit, in my mind are nothing less than freak cars. These the public have bought until the last twelve months or so fairly extensively, and obviously paid the penalty. Whereas, no one can gainsay the fact that the Continental manufacturers are now only putting on the market designs proved by sound practice and long experience. Englishmen are not slow to appreciate the benefits arising out of buying cars from firms who possess works in the country, where parts are always obtainable on the spur of the moment, where inspection can be carried out at the buyer's discretion, where any defect in design or manufacture can receive prompt consideration, and where special models can be built up without loss of time, &c., &c. These are features which appeal to the commercial user extensively.

There are many in the motor trade holding the opinion that those bodies responsible for watching the trade interests should be subdivided into British and foreign. But I am one of those who consider such a policy suicidal to the best interests of the movement. The result of the last Olympia Exhibition is certainly a conclusive proof of what can be attained by unanimous action, and both British and foreign makers and traders may congratulate themselves upon the splendid manner in which they supported the Society of Motor Manufacturers and Traders over this Show. The large increase in trade, and other benefits, which have been derived, due to the united front displayed by the trade, are, to my knowledge, very considerable, and will be felt still more in the coming year.

To conclude, the progress of the British industry must, in my opinion, advance with the development of the movement. That the British industry will prove pre-eminent, is obvious, but this is a question of time. "Slating" the foreigner does not lend dignity to our posision, neither is it consistent with our best interests, as without him the public sympathy in automobilism would never have been attracted to the extent it has been, and, after all, that is the main goal to which we are all working.

It appears to me that, until a tariff is fixed, there is no commercial inducement for the prospective purchaser to favour the British manufacturer. Ardent patriotism is essentially a desirable feature in the politician, but I consider it an unnecessary quality in the motor manufacturer.

Yours truly,
SIDNEY STRAKER.
SIDNEY STRAKER AND SQUIRE, LIMITED.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—My attention has been called to Mr. Chas. Jarrott's letter and the extraordinary conclusions he comes to. I join issue with your correspondent on his first material statement, which is, if foreign cars had been taxed in the past, the motor industy in this country would have been, and would be now, considerably retarded. On the contrary, if we had had the commonsense to substitute for some aimless tax a duty on foreign cars, and giving Mr. Jarrott, for the moment, all he can possibly claim by tentatively agreeing that we should have paid all the tax ourselves to ourselves, the position to-day would be that instead of exporting three millions, or thereabouts, in gold, and importing three millions in cars, we should have in this country the gold and the cars, and at no cost to ourselves—if the duty had been large enough to make it unprofitable for the foreigner to import cars which can be made quite as well in this country by its workers.

It has never been suggested by any responsible tariff reformer that we should pay more in taxation than even the most rabid misnamed free trader has to admit we already pay to-day.

If the totally unthought out, and even stupid tax on tea (which we can never make in this country, and which in no sense of the word is a luxury) had been removed and applied elsewhere, to motor cars for instance, with a well thought-out object, the majority of alien cars at present made in foreign countries for their benefit would have been begun to be manufactured in this country long since.

I doubt if there are any foreign makers of repute who have got it under contemplation to commence manufacture in this country directly our fiscal system is put into line with all the other highly intellectual and highly civilised nations of the world. One instance, perhaps, will suffice.

I am in a position to state that if a tax had been imposed which would handicap the foreign maker against the home maker, the famous firm of Panhard and Levassor would have taken works adjacent to here, and manufactured their cars for this market, in this country. I do not know for certain the amount of the sales of Panhard cars here in a twelvemonth, but I do know that it is many hundred thousands of pounds. At the present time we have the very excellent cars. France, and the firm named, have our not excellent money. I say that, admitting for the sake of simplifying the argument, that we paid the whole of the tax, it was, and is possible, without paying one penny more in total taxes, to have both the cars and the money for this country. As far as this village is concerned, £2,000 per week at least would be being paid in wages, that money would be filtering through every nook and cranny of our social fabric, would be benefiting every man, woman, and child in this parish and far beyond it. I maintain that we should not pay the tax, but nevertheless, I say that it is quite unimportant if we do, seeing that we pay it to ourselves. I know that, rather than be beaten out of this important market where their vested interests are now so very large, the foreigner will pay every red cent of the tax, until such time as we adopt his deliberate real high tariff with the set intent of having nothing manufactured outside his country which can be manufactured inside it for its benefit.

Will Mr. Jarrott deny that a suitable tax could not have compelled us to have large motor factories scattered all over this country, under foreign control and supervision if he likes, and if he admits the possibility, will he dare to repeat his broad dictum that the motor industry in this country would have been, and would be now, considerably retarded? No, this is not what Mr. Jarrott means. He has accused in his letter some unknown to me contributor or speaker of want of good faith by suppression of material facts. No, that is not what your correspondent means, when he pens words to conceal his thoughts. He means that the occupation of gentlemen, such as he, sitting in an office and engaged in the exploitation and importation of foreign cars would have been considerably retarded!

It probably is a fact that the attacked speaker, instead of erecting his own factories, had induced the enterprising foreigners to build their own factories, &c. But why? because the scientific tariff imposed by every intelligent nation throughout the world, without exception, gives this British maker of motor cars not the faintest chance of building cars in this country for exportation to abroad.

If by retaliation or "a blow for a blow," instead of maudlin sentiment of "turning the other cheek," we compel the foreigner to abate his duties or else take the consequences in the shape of a depleted purse, then there would be no necessity to make arrangements for well-known brands of British cars to be manufactured inside the market they are intended for.

If cars could be imported into foreign countries as freely as they can be imported here, your readers can rest assured that no such arrangement as that indicated would ever be made. We British makers would leave agreements with the foreigners alone, and have our own brands of goods made by our own people.

Your correspondent is kind enough to admit that three well-known home motor car manufacturers exhibited at the Paris Salon, not for the purpose of selling cars in France, but to increase their status at home, forsooth, a sort of "Charge of the Light Brigade"—magnificent, but not commerce. Never mind how many cars they have delivered in France for use in that country, I ask them to deny my assertion that the net profit to date they have made out of selling cars in France would not pay Mr. Jarrott's rent for a week! Is it not possible that the Italian firms went to the Paris Salon for the same reason, to give them a standing in their own country and to meet patriotic Englishmen engaged in the exploitation of foreign cars and the writing of letters to the newspapers for the maintenance of their livelihood?

Your contributor states a large number of German cars are sold in France in every year. I deny *in toto*; it is an absolutely misleading statement, and is not due to ignorance. There are no German cars sold in France except one famous make, and the majority of those cars are sold to Americans in Paris. There is neither a large nor a ready sale in America for foreign cars, and the number of cars on which forty-five per cent. duty is paid is very small. Mr. Jarrott "carefully omits" to state that it is highly important, from the American's point of view, to always use his car a certain number of months in Europe so as to get a very large abatement on the heavy duty if he takes it into his own country. As the American tariff has been drawn attention to, perhaps it will be explained to us how it is that in poor protected America, with bad roads or no roads at all, there are at least ten times as many cars made as here. Greater population alone cannot account for it.

Allow me to anticipate Mr. Jarrott on one point. The duty on British cars into France is purposely not very heavy—about £20 each—because the French people have nothing to fear from us just now, but directly they have, then the duty will go up until the balance is restored in the eyes of this, the most intellectual nation in the world.

On cycles, however, the duty comes to nearly 30*s.* each. At the Paris Salon twelve months ago, I negotiated with one of the best known houses in France, whose name is a household word, for the supply of 5,000 bicycles to be made in Birmingham.

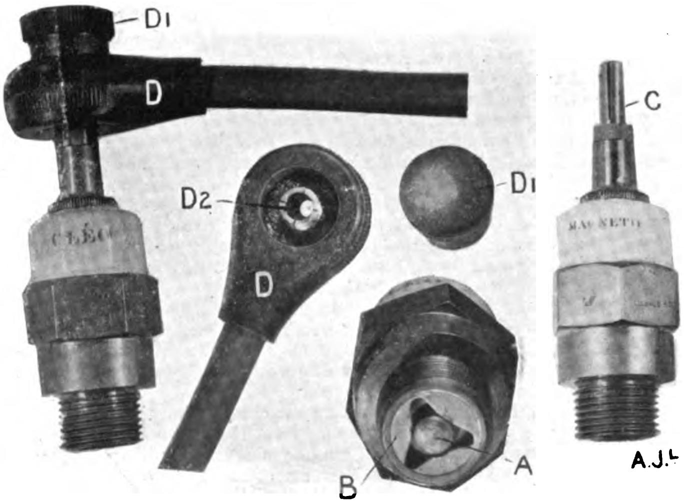
Careful calculations were gone into, and it was found that owing to the French makers devoting greater attention to car construction, and, therefore, to an extent, losing their grip on the cycle trade, that we, in this case the foreigner, could just pay the duty to the Frenchman and compete (it is just as well to have this proposed transaction clearly in ones mind, the Frenchman was to get as good a bicycle as at present, and for the same price, and we were to pay him 30*s.* each bicycle for the privilege of supplying it). But the negotiations fell through, and for one reason only. The French firm said, "It is the deliberate intention of our Government not to have anything manufactured abroad which can be made equally well in France. The present duty is 30*s.*, but directly we begin to import large numbers of cycles, our cycle workers will draw the attention of the Chamber to the fact, and the duty will be increased to 40*s.*, to 60*s.*, to 120*s.* each, or any such sum as may be necessary to put you out of the market. It is no use for us to attempt to establish a business which cannot last. I do not think that the French nation will have one policy in regard to cycles, and another policy with regard to motor cars.

The great authority, Mr. Charles Jarrott, came back from the Paris Salon two years ago, and went out of his way to write to the papers warning the British makers against being copyists by using honeycomb radiators, channel steel frames (chassis *embouti*), and mechanical valves. I challenged his statement, and time has shown that every car of repute, including those for which Mr. Jarrott is agent, have embodied in them, without exception, the three points I wrote should be adopted by every British maker, despite the advice given to the contrary. In this case Mr. Jarrott has proved a poor prophet. I now give him an opportunity for retaliation by indulging in a little prophecy myself. I say that if the present 45 per cent. duty into America is maintained, that in three years from now there will be no French or German new cars whatever sent into that country.— Yours faithfully,

Birmingham, CHAS. SANGSTER.
Jan. 6th.

⊛ ⊛ ⊛ ⊛

THE LACOSTE OLEO-MAGNETO PLUG.



ALTHOUGH it is not essential to use a special ignition-plug with high-tension magnetos, yet it is not every ordinary make which is really suitable for such work. Some firms are, therefore, constructing plugs embodying the features which they consider most desirable in this connection, and among such are the makers of the well-known Oleo plug. This has been placed on the market as the "Oleo-magneto" plug, but Messrs. Lacoste have added an improvement of their own, and are now marketing the complete device which we illustrate herewith.

The plug itself is of exceedingly substantial construction, and its most important point is the solidity of the sparking terminals, A and B, which provide three alternative gaps. This is done in order to enable the spark to vary its path, and, in consequence, to prevent the too rapid burning away of the points.

Messrs. Lacoste's contribution to the design consists of the very neat terminal provided for attaching the wire. Instead of the ordinary screw terminal, a split spigot, C, is fitted to the top of the plug, and this retains the detachable terminal, D, by friction only. The terminal, D, is formed of ebonite and brass, and it has a brass-lined screw-cap, D^1, which presses down on the end of the wire, thus ensuring a good contact. In the illustration the method of attaching the wire itself is clearly indicated. When required, the spigot, C, can be removed, and the ordinary screw terminal reinserted.

⊛ ⊛ ⊛ ⊛

The "Thery" Car.

THÉRY, the famous racing driver, is to take charge of a new establishment in France, where cars, to be associated with his name, are to be manufactured. Messrs. Mann and Overton, Limited, will be the sole agents in England for this "Gordon-Bennett" Car.

IMPORTS AND EXPORTS.—Complete Table of Imports and Exports of Automobiles to and from Great Britain.

Prior to 1900, motor cars and motor cycles were merely included in the Board of Trade Returns under a general heading of "goods, unenumerated, manufactured," and during the years 1900 and 1901 they figured only amongst "carriages, wagonettes, carts, &c. In 1902 and 1903 motor cars and motor cycles were separated from the general heading, but were even then taken in one total together. It was only in 1904 that separate returns for motor cars and motor cycles, and their respective parts, were issued by the Board of Trade under special headings. We have from month to month published these, but in view of the recent prominence given to this important subject, we have brought the whole of the figures, since 1902, together in one table. We refer to these figures editorially.

* Not divided until 1904.

RACES, RECORDS, AND TRIALS.

Melbourne-Sydney Reliability Contest.

LAST week we concluded our account of this "overland" trial in Australia, by giving a list of the five competitors who were still "running" with a margin of marks to lose. Hobbs and his Mercedes was the only competitor who still had an absolutely full score of marks, which might lead to the supposition that under the circumstances the Dunlop Cup would go to him. Under the rule, however, all those who tied over the Melbourne to Sydney course, were started on their further runs, as enumerated by us last week, with ten points each to lose for engine stops, &c., and so long as any competitor had one of these 10 marks left, he was considered as co-equal with the other "ties" still running. As the cars had every appearance of being capable of continuing the tests until further notice, an awkward position was presented. The Dunlop Rubber Company, who had organised the trial, therefore decided not to continue the run, considering that the contest had served its purpose by the return run to Melbourne. The promoters, therefore, with the consent of the competitors, made the following arrangement :—The "Dunlop Cup" to be inscribed with the names and performances of the five contestants, and the Automobile Club of Victoria to be asked to hold the Cup on their behalf for the next twelve months. In the event of one of the five contestants winning the Cup next year the trophy to become his own property. Mr. G. Hobbs, in recognition of his fine performance, to be presented with the Motoring Road Blue Ribbon of Australia and gold medal, together with the Bailleau Trophy; Messrs. W. R. Grimwade, W. B. Wilkinson, and H. Tarrant to each receive a Dunlop Trophy, of similar design and value, together with gold medals; Mr. S. Day to receive the Robert Hurst Trophy and gold medal.

T. K. Rand in trouble on Razorback Mountain with its 1 in 6 grade.

C. E. Liddel's Panhard Car surmounting Razorback Mountain.

MELBOURNE-SYDNEY RELIABILITY TRIALS.

And thus endeth the second memorable contest for the splendid trophy presented by the Dunlop Company.

Last week we gave a number of interesting pictures of the event, and this week we are enabled to supplement these by a series of striking photographs, including some of the "run off" between the full mark cars for the Dunlop Cup. The five competitors and their cars, who will now hold this Cup jointly, are shown in our frontispiece.

In our table of results, published on page 8 of our last issue, the names of the cars driven by Messrs. Wilkinson and Grimwade were, by a slip, transposed, although in the text it will be seen the right cars were attributed to each. Mr. Wilkinson drove the 10–12-h.p. Talbot car, which made best time in its class—B—and Mr. Grimwade drove the 10-h.p. Argyll.

French Motor Grand Prix.

OF the large number of circuits proposed for the French race of this year, the "Circuit de la Brie" is receiving very favourable consideration at the hands of the French Club. In fact, out of about 10 circuits which are regarded as having any chance of selection, the Brie course is placed as even; Seine-Inferieure (Dieppe), 4 to 1 against; Fontainebleau, 6 to 1; Argonne, 10 to 1; Calvados, 20 to 1; Auvergne, 25 to 1; Aix-les-Bains, 50 to 1; Mans (S. et O.), 100 to 1; and La Loire, Nivernais, and Mayenne, 150 to 1 against each. The Brie circuit proposed is a triangle of about 110 kiloms. from Melun to Montereau, *viâ* Sivry; from there to Provins, *viâ* Donnemarie and Longueville, and thence back to Melun *viâ* Maison Rouge. An alternative route differing in detail is also proposed. There a *possibility* that the race may extend over two days!

A fine stretch of road on the "run-off" from Sydney to the Blue Mountains and back. G. Hobbs making good time on his Mercedes.

Coming down the Blue Mountains, N.S.W., on the "run-off" for the Dunlop Cup. The leading car is W. B. Wilkinson's 10–12-h.p. Talbot, the car in the distance being A. Fauvel's 12-h.p. Richard-Brasier.

MELBOURNE-SYDNEY RELIABILITY TRIALS.

Resilient Wheel Trials.

Broadly, the basis for the rules governing the proposed resilient wheel trials in France, being organised by *L'Auto*, has been agreed. The date is to be between March 15th and April 15th; cars, upon which any device is fitted, must weigh, fully laden, at least 1,500 kilogs.; the distance is to be about 3,000 kiloms. in 10 stages, at an average speed of 30 kiloms. per hour; maximum piston displacement, 3½ litres; drivers may be changed; repairs must be made by those in the cars; observers will report performances, and closed "parcs" are to be enforced.

The trials will not take place this year, in the event of the proposed pneumatic tyre trials of the A.C. de France being held—a contingency which is thought to be unlikely.

An Ideal Abandoned.

The Automobile Club of Germany have withdrawn for 1906 their suggestion that the European clubs should agree to hold one big international contest only during the year. They propose, however, to revive this suggestion for later years.

Crystal Palace Motor Show.

This Exhibition opens on the 26th inst., closing February 3rd. A new feature will be the use of one of the lakes for motor boat trials.

Contest of Public Vehicles.

The full title of the company which secured a silver-gilt medal in the contest for public vehicles for town use, recently held in Paris, and of which we gave a report on December 30th, is "Compagnie de Française des Voitures Electromobiles."

MELBOURNE-SYDNEY RELIABILITY TRIALS.—A few of the competitors indulging in an al fresco afternoon tea at Strathfield Control, Sydney.

The Next Tourist Trophy Race.

THE secretary of the A.C.G.B.I., last week, went over to the Isle of Man in connection with the arrangements for holding the Tourist Trophy Race in the island this year—possibly in May.

Middleton Hub Long Distance Test.

THE report of the Automobile Club has now been issued of the 4,000 miles long distance trial from November 21st to December 22nd, under ordinary touring conditions, to which the Middleton Pneumatic Hub, described by us fully recently, has been subjected under the supervision of the Club officials. From this it will be gathered that the trial has resulted in an extremely satisfactory performance. Subsequent to the trial a further short run was made by Col. Holden and Mr. Worby Beaumont. The wheels were then removed, taken to pieces and examined by them for wear and condition. The following is the official report in regard to the whole trial:—

The side plates and connecting driving studs were in good order, the wear of the faces being practically nil. The studs were not worn, but the rubber sheathing which had been put upon them had been ground to powder.

The pneumatic tube supporting discs showed no wear.

The nuts on the ends of the connecting driving studs were screwed down on to the side plates with intervening Thackeray spring washers, which seem to have retained the nuts quite satisfactorily.

Of the pneumatic tubes, three were replaced during the trial, and one lasted throughout the trial; its condition justifies the expectation that its mileage might have been considerably extended before failure. Of the three tubes which failed, one had been run 6¼ miles deflated (on the 1st December, 1905) and was then replaced. This tube does not appear to have been worn through, and at the time of the examination still held air put into it after removal. The main body of the material of the tube was, however, separated in a circular mid-section line, except as to the interior rubber lining, and this was apparently due to mechanical pressure in the working of the wheel. In other respects this tube might be roughly described as half worn out. The other two tubes, whose failure is reported, failed from what may be termed disintegration, resulting from the combined effects of internal pressure, the bearing upon the edges of the inner supporting discs, the relative motion of the wheel ring and hub plates, and the alternating compression and release of the vertical walls of the tube as the wheel rotates under load.

The fact that a wheel may be run with a deflated tube is one of interest to the user, especially as it appears that the tube is not damaged by running a few miles in that condition, and that the fact that it is deflated is not readily detected by those riding in the car. This points to the importance of the part played by the solid rubber tyre in connection with this device, and leads to the suggestion that the true way to test the efficacy of the pneumatic hub would be to try it in conjunction with iron tyres.

The condition of the solid rubber tyres used in the trial was noticed, but does not call for remark with regard to the pneumatic hub.

The diameter of the wheels over the tyres was 34 ins., and the weight of the wheels was as follows:—Back wheels with sprocket, 185 lb.; front wheels, 176 lb.

The trial may, as a consequence of the bad condition of the roads, be considered to have been unusually severe, both for the pneumatic hubs and the car, a 16-20-h.p. Florentia, the running of which throughout the trial will be seen to have been consistently reliable.

Number of Miles Run per Wheel, without Involuntary Stops.

Petrol Consumption.

287 gallons 3 quarts: 13·9183 m.p.g.

Circuit Européen.

A MEETING of the International Clubs taking part in this big trial is announced to be held on the 20th inst. at Berlin.

On page 1538 of our last volume we published a table giving the leading particulars of the regulations governing each of the four categories into which this event is to be divided. These classes, it will be remembered, are governed by piston *area*, but unfortunately an error crept into that table, mm.^{3} appearing instead of mm^2., and the decimal point being shifted one place so that the figures were given ten times their real value. This obvious slip can hardly have caused any real inconvenience, since actual dimensions were also given in the same column, but we take this opportunity of repeating the maximum total piston areas (in square millimetres) for each class, which are as follows:—Cat. I. 8,659 mm.^{2}; Cat. II. 22,619 mm.^{2}; Cat. III. 34,636 mm.^{2}; Cat. IV. 53,092 mm.^{2}.

⊛ ⊛ ⊛ ⊛

MOTOR BOATING.

Mediterranean Cup.

IT has been decided that the running of this race in 1906 shall be abandoned, the next contest being fixed for 1907.

Coupe de la Riviera.

IN April, this Cup is to be contested, a start being made on April 17th from Nice for Toulon. On April 19th, the return journey will be made to Nice, with a stop at Cannes, to enable competitors to take part in the Burton Cup Race on that day. The next journey, on April 20th, will be to Genoa, and on April 22nd the return to Nice takes place.

⊛ ⊛ ⊛ ⊛

MOTOR CYCLING.

Auto Cycle Club's Annual Dinner.

MEMBERS are again reminded that the annual dinner of the club will take place on Wednesday next, January 17th, at the Criterion Restaurant, Piccadilly Circus, W., at 7 for 7.30 p.m. The chair will be taken by Mr. Robert Todd, who will be supported by Earl Russell, Sir Martin Conway, Col. H. C. L. Holden, and others. Several well-known motorists have unfortunately been prevented from attending owing to the general election; the tickets are, however, going off well, and there is every prospect of the dinner being a great success. An attractive musical programme is promised between the speeches.

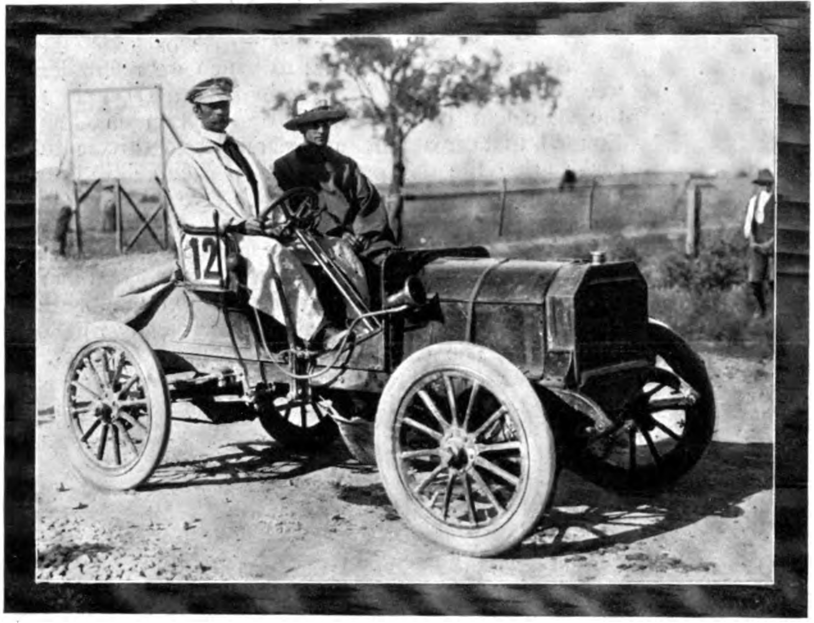
Those members who have not already booked seats should do so without further delay on the form which has already been sent out.

Quarterly Trials.

ENTRIES close on Monday next, January 15th, for the First Quarterly Trial of the Auto Cycle Club, which is to take place on Saturday, January 20th, starting from the Chequers Hotel, Uxbridge, at 9 a.m. The route will be *viâ* Beaconsfield, High Wycombe, Dashwood Hill, Wheatley, Islip to Banbury, returning *viâ* Bicester, Aylesbury, Berkhamsted, Chesham, Amersham, and Beaconsfield to Uxbridge. We would remind our readers that the entrance fee is one guinea to manufacturers or agents. Private owners, who are not interested either directly or indirectly in the machine which they are riding, and which must be their own property, can enter for half-a-guinea.

International Cup for Motor Cycles.

THE eliminating trial for the selection of three machines to represent Great Britain in the race this year, will be held, probably, in May, in the Isle of Man.



MELBOURNE-SYDNEY RELIABILITY TRIALS.—H. Tarrant on his 8-10-h.p. Tarrant Car with which he tied with four others for the Dunlop Cup, after driving 1,276 miles. This car, it will be remembered, is an Australian car, built in Melbourne.

The Endorsement Absurdity Again.

A CRASS example of the absurdity of the Act which necessitates the endorsement of the holder's licence if convicted of no matter how trivial an offence, was afforded last week at Lowestoft. Mr. Mawdsley Brooke was driving through the town on the evening of the 17th of December, when one of his lights went out owing to a leakage of oil. The Bench proceeded to fine him 10*s.* and costs, when to the surprise of the "Court" it was pointed out by the clerk that in that case his licence must be endorsed. After considering the matter and finding that such was really the preposterous law on the subject, the Bench revised their decision, as Mr. Brooke's licence had never been endorsed before, and refused to convict, ordering him merely to pay the costs amounting to 5*s.* 6*d.*

Motor Funerals.

THE automobile hearse is an institution which we knew was certain to come sooner or later. We remember some years ago a funeral in a prominent Midland town in which all the vehicles forming the procession were self-propelled excepting the principal one, but now this difficulty has been got over in Paris, and funerals which are automobile from the hearse to the last mourning coach are to become a regular phenomenon. The difficulty hitherto has been to secure a sufficiently slow and sedate pace, but that we believe has now been surmounted. On the return homeward after the ceremony a higher gear is usually employed. Messrs. De Dion exhibited a motor hearse among their commercial vehicles at the Paris Salon, although, in order not to damp the ardour of business enquirers, it was not given undue prominence.

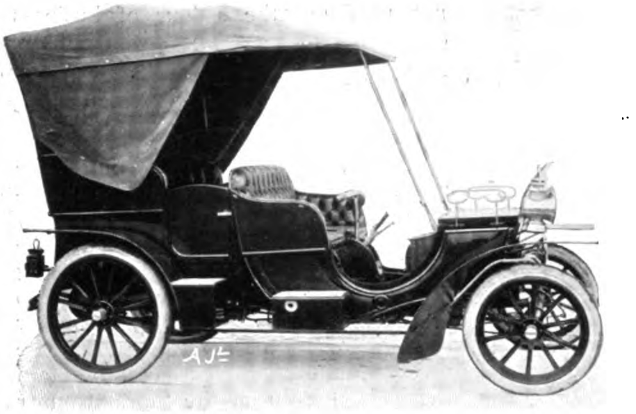
The Pushfulness of Surrey "Bumbles."

THAT the authorities of Surrey are not deficient in—well, let us be charitable and call it assurance—is shown by a letter which has been written by the Clerk of the County Council, requesting all persons resident therein who have to take out licences for carriages, motor cars, motor bicycles, dogs, guns, male servants, and other kickshaws, to obtain these licences from the Surrey County authorities, so that the said Surrey County authorities may benefit from the funds that thereby accrue. Considering the systematic persecution to which motorists have been subjected in the county, we trust that most residents, particularly automobilists who have to take out or renew licences during the coming year for any of the above luxuries, will apply, even at inconvenience to themselves, in some county where motorists are treated with more consideration.

Tragic Coincidence.

ONE of those coincidences which almost appear to have something of the supernatural about them, occurred at Markyate, the village in Hertfordshire where last summer a small boy was run over and killed by a car under painful circumstances. The King's motor cars were passing through the same village on Tuesday last when a puff of wind blew away the cap of Mr. Barnes, one of the servants, as he was engaged in putting it on. He made a snatch at it, and was thrown violently from the car, sustaining a fatal fracture of the skull.

MELBOURNE-SYDNEY RELIABILITY TRIALS.—Last week we gave a picture of S. H. Day's 8-h.p. De Dion, one of the cars which tied for the Dunlop Cup. The above view shows very plainly the broken front springs of the car, in which state this car was driven for the last 500 miles of the trial. The car was a three-year-old single cylinder vehicle.



The first of the new 1906 models of the 15–18-h.p. British Duryea Cars.

CLUBS AND ASSOCIATIONS.

Aero Club.

AMONGST the new members elected to the Club at the meeting held last week were :—The Hon. Mrs. Burrell, Admiral Sir Charles Campbell, K.C.M.G., Lord Llangattock. Mr. Lionel de Rothschild, Mr. A. J. Orr Ewing, Monsieur Paul Tissandier, son of the celebrated French astronomer ; Count d'Oultremont, President of the Belgium Aero Club ; Count de la Vaulx, Vice-President of the Aero Club de France ; and Monsieur Jacques Faure, who went from London to Paris by balloon, and recently won the Aeronautical "Grand Prix" by travelling from Paris to the borders of Russia, a distance of 800 miles in 18 hours.

British Empire Motor Trades Alliance, Limited.

THE following firms have been elected to :—

Membership: Adams Manufacturing Company, Limited, Austin Motor Company, Limited, D. Napier and Son, C. S. Rolls and Co.

Associate Membership: Sirdar Rubber Company, Limited.

Committee: Austin Motor Company, Limited, D. Napier and Son, C. S. Rolls and Co., Wolseley Tool and Motor Company, Limited.

Northamptonshire A.C.

A MEETING of the Committee of the Club was held last week or the purpose of electing a president, vice-presidents, other officers, and members, also to adjust rules, and to complete the organisation of the club. Sir Thos. Hesketh, Bart., was in the chair. The following were elected :—

President.—The Right Hon. Lord Lilford.

Vice-Presidents.—Sir Thos. Hesketh, Bart., Major G. E. T. Hibbert, Mr. Harry Manfield, J.P., Lieut.-Col. A. F. Mulliner, V.D.

Committee.—Messrs. C. W. Bartholomew, F. Gorrell Barnes, Humphrey Bennett, Frederick Bostock, Capt. W. Briggs, Messrs. A. H. Bryan, Leslie W. Dryland, Col. C. E. Foster, Messrs. Henry Hawkins, W. A. Henshaw, Thos. Horton, J.P., A. A. Hope, G. H. Lewis, Chas. W. Phipps, Rev. W. Seggins Pratt, Rev. M. Pitchford, Major Leslie Renton, Captain Sowerby, Mr. W. M. Wroughton, M.F.H., Councillor S. Yarde.

Mr. Sidney F. Harris, Weston Favell, Northampton, was elected Honorary Secretary of the Club, and all communications appertaining thereto should be addressed to him at his office, 1, Sheep Street, Northampton. The election of the other officers of the club was held over for another meeting.

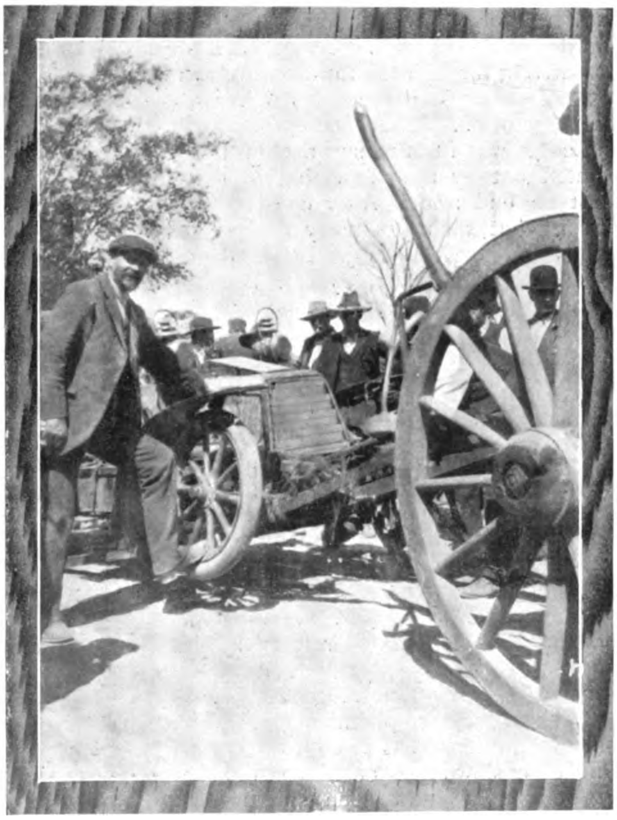
⊛ ⊛ ⊛ ⊛

A Useful Companion.

A VERY useful and compact pocket measure, which embodies comparative measurements for practically all everyday purposes, is to hand from Mr. J. M. MacLulich, managing director of the Sirdar Rubber Company. This little memento is a pleasant accompaniment to Mr. MacLulich's New Year's greetings.

Fine for Renewing a Driving Licence: Non-use of your Car for one (or more) Days.

APROPOS of the subject to which we referred last week, the renewing of licences by local authorities, and the statement by the official of the London County Council, that car owners must refrain from driving their cars during the day or two that is occupied in the renewal of their licences, we would observe that the situation certainly appears to be far from satisfactory or even sensible. It may appear to the registering officials no hardship that car owners should be deprived of the use of their cars for that length of time, as presumably they employ them mainly, if not always, for merely frivolous purposes. The case of a business man, however, to whom the car is a requisite for obtaining his livelihood, or carrying on his business, seems to have been neglected altogether. The Clerk of the County Council makes a great merit of having in some cases returned the driving licences on the same day that the renewal was applied for. Why there should be any delay is certainly something of a mystery. Season ticket holders on railways are in the habit of walking into the office when they renew their tickets, and having the new tickets issued to them while they stand at the counter, the total time occupied being seldom more than about ten minutes. Why our public authorities should be incapable of equal despatch is one of those many mysteries of British organisation which will presumably furnish food for discussion to archæologists and other students of quaint customs in the dim and distant future.



MELBOURNE-SYDNEY RELIABILITY TRIALS.—
The above picture is not a representation of a new machine-gun in limber. It is D. Mackenzie's 12-h.p. Darracq Car being assisted after its trouble with a broken front axle at Euroa.

"Direct-Drive" Monopoly in France.

IT appears that the majority of automobile manufacturers in France have now arrived at a compromise with the Renault firm, and have agreed to pay a small royalty on all live-axle, direct-drive cars sold by them on and after January 1st last. This arrangement cannot, of course, in any way affect the validity or the scope of the corresponding English patent, concerning which we have already given full particulars in these columns.

Motor Cars and the General Election.

THE importance of motor cars to the coming election is being recognised by manufacturers generally, and the Wolseley Company are bringing out special machines designed particularly for standing the rough work to which they are likely to be exposed, provided with suitable bodies for the purpose, and put on the market at a comparatively low figure. To what extent candidates or organisations will be prepared to go to the expense of buying cars for electioneering purposes only is, of course, a question, and no doubt can be entertained as to the enormous value of a good supply of vehicles on polling day, and before it, to any candidate who has to fight a closely contested election. It will be remembered that the hiring of vehicles, that are either regularly let out for hire or kept for that purpose, is distinctly illegal under the Corrupt Practices Act, and that any candidate who either himself, or through his agent, employs them, or whose friends hire such vehicles for his assistance to take electors to the poll, is likely to be unseated on petition. In any case those cars might be provided with cheap and strong bodies of the workshop order, though, perhaps, a little more externally attractive, and when the stress of the election is over they could be fitted with more luxurious bodies for regular use.

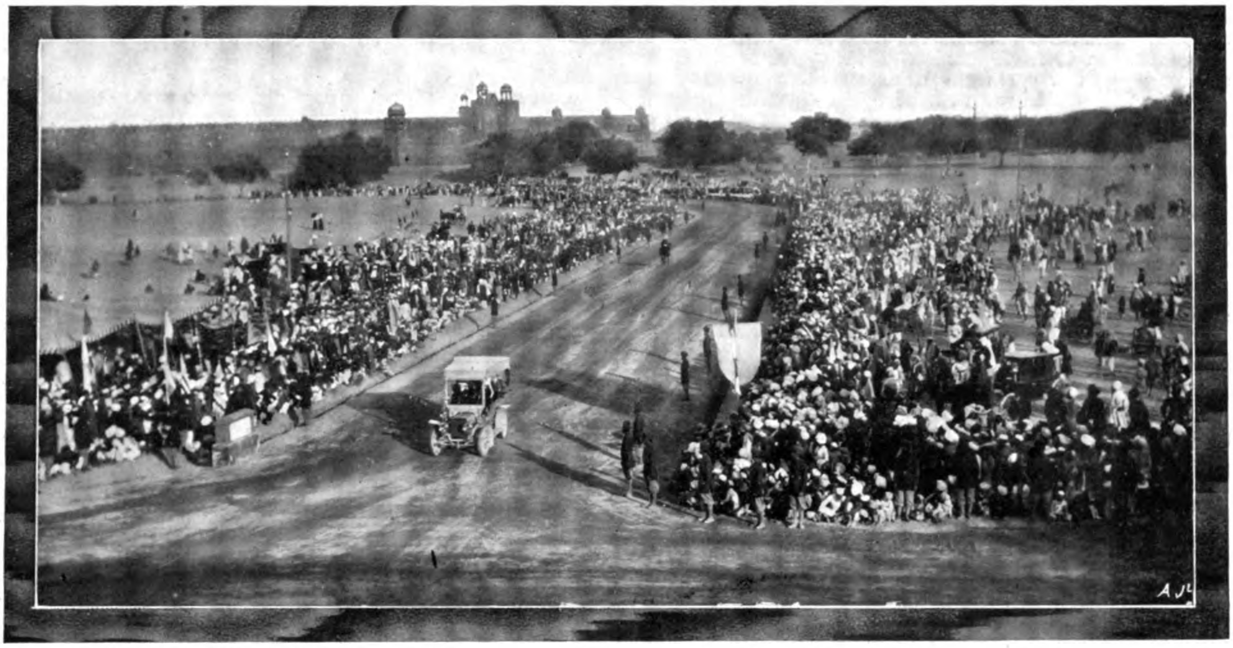
Motoring Parliamentary Candidates.

THE Scottish Automobile Club send us the following list of their members who are candidates for Scottish constituencies :—

Dumbartonshire	Col. Henry Brock.
Kincardineshire	Mr. S. J. Gammell.
Lanarkshire (Govan Division)...	Mr. Harry S. Murray.
Linlithgowshire...	Mr. Alex. Ure, K.C.
Renfrewshire	Sir Thomas Glen Coats, Bart.
Roxboroughshire	Sir R. J. Waldie Griffith, Bart.
Edinburgh, West	Sir Louis McIver, Bart.
Glasgow, Blackfriars	Mr. A. Bonar Law.
Kilmarnock Burghs	Mr. T. W. Macintyre.

New Peer's Title.

BARON NORTHCLIFFE, of the Isle of Thanet, in the county of Kent, is the new title selected by Sir Alfred Charles William Harmsworth, Baronet, upon his elevation to the Peerage.



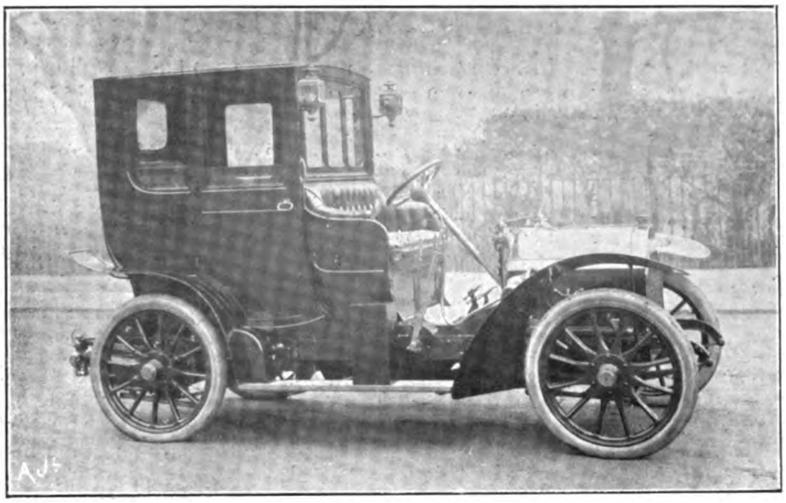
THE ROYAL VISIT TO INDIA.—Motor cars are being very largely used by the Prince and Princess of Wales and their accompanying suite during their triumphal procession through our Indian Empire. In the picture the Prince and Princess are arriving in one of their cars at the Mosque of Jumma Masjid. Their Royal Highnesses were staying at the house built for the Delhi Durbar and in the afternoon motored out and visited the Fort and the Mosque. The route between the Fort and the great Mosque, shown in our picture, was lined by thousands of school children carrying banners with mottoes.

A Generous Offer and its Result.

BY way of marking the advent of the New Year, Messrs. Charles Jarrott and Letts, Limited, determined to send gratis to any of our readers a very artistic little oxydised paper-knife which has been prepared and issued by Messrs. De Dietrich, of Luneville. We gave an illustration of this little present in our issue of December 30th last and mentioned the above facts. As a result, under date of January 8th, we have received the following communication from Messrs. Jarrott and Letts :—

> "Will you be good enough to just put a line in your paper to the effect that those readers who have applied for paper knives, but have not received them, may rest assured that their letters are not ignored, but the applications have been so numerous that the supply is for the moment exhausted. We are, therefore, awaiting a further quantity from Paris. It may interest you to know that we have received five hundred applications for these knives."

Any other readers wishing to secure one of these mementos should lose no time in "booking their order."



A new De Dietrich Brougham specially constructed for town use. It is the first of its kind built by the Luneville firm. The chassis is shorter than other De Dietrich models, giving greater flexibility in traffic and narrow streets. Apart from the driver, there is seating accommodation for four. It was, we learn, a car of this type which secured a Silver Medal in the recent Paris contest for carriages for town use.

To Make Motor Cars.

THE Birmingham Small Arms Company have decided to add the manufacture of motor cars as a "side line" to their business.

An Example to Follow.

NEXT to obtaining a good car is the necessity for securing a good driver, in order to reap the full benefits of automobilism. We are not at all surprised to find, therefore, that Mr. S. F. Edge has decided to deal with this matter, as far as the Napier cars are concerned, with his characteristic energy and thoroughness. In order to supply his clients with really reliable men, Mr. Edge has instituted a training department in which he has would-be drivers taught not only the rudiments, but the full details of their profession. Needless to say, the scheme has been started on a thoroughly sound basis and, while open to all, every precaution is taken to ensure that only desirable men enter upon the course of instruction, and none but the proficient leave it to take service elsewhere.

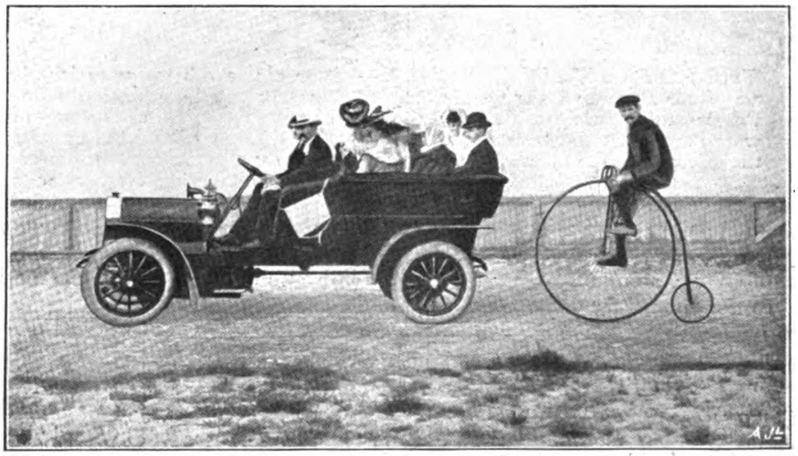
This is, of course, as it should be. For those who are anxious to follow the calling —and there must be many less varied existences—the scheme should be an unqualified boon, for not only are they put in the way of acquiring sound practical knowledge, but they receive a salary at the same time. It is a business proposition from first to last, and Mr. Edge realises only too well that the greater part of the "trouble" experienced with the modern car is due solely to the inefficiency of the driver. Now that the powerful car is becoming more and more a vehicle in which to make journeys as well as to tour, the owner will think twice before engaging a driver who is not an expert in his knowledge of the particular car he is required to drive. Such proficiency has either to be obtained at the owner's cost or the manufacturer's—which renders further comment on Mr. Edge's proposals superfluous.

Rushing the Pole.

THE schemes of M. (Ant)Arctowski for invading the Southern Continent, and if possible reaching the South Pole by motor car, have partially crystallised into a slightly more detailed form. He now proposes, at any rate, to land at the foot of Mount Terror, the spot where the "Discovery" wintered in the 78th degree of latitude. It is "only" (!) 780 miles from that point to the Pole. By utilising three motor cars M. (Ant)Arctowski *thinks* he will be able to reach the Pole. We wonder what some of Captain Scott's dogs, who lie at the bottom of chasms and fissures in the ice, would think about it if they could return to life.

6-h.p. De Dion Cars for 1906.

So justly popular has the 6-h.p. De Dion car become with those requiring a well-built and capable little car of low power, that many of our readers will learn with regret of the exclusion of this model from the regular programme of the manufacturers during the coming season. The arrangements made by the English Company will, however, enable them to still supply a limited number, fitted with three forward speeds and a reverse, to their customers, but it has now been definitely decided that no new model of this power will be introduced this year—in spite of the rumours which have floated about suggesting the appearance of a cheaper 6-h p. vehicle. During this year, therefore, the smallest standard car engaging the attention of this celebrated factory is the somewhat more powerful, single-cylinder 8-h.p. machine.



THE PAST AND THE PRESENT.—Occasionally in out-of-the-way country districts one is startled by the sight of a relic of the past in the form of an old "ordinary" bicycle. As in the case of deceased donkeys, it has always been more or less of a mystery what becomes of them. We are able to account for one of them anyway, in the above photograph, which was secured in Australia in November. H. Tipper, well-known in Sydney athletic circles, is the rider on the "ordinary," and the car is a 16-h.p. Argyll, driven by Mr. H. S. Cusack.

At the November Olympia Exhibition, one of the most striking features in the decorations of the many charmingly designed stands, was the pair of huge pictures which were suspended over the Ducros-Mercedes exhibit. At the Show, it was not easy to obtain satisfactory photographs of these, but we are now enabled, by the courtesy of the firm, to place them upon record in our pages. Above we reproduce the one—the second being given below.

COMMERCIAL POINTS.

United Motor Industries.

AT the recent annual general meeting, as also at an extraordinary general meeting, of United Motor Industries, Limited, a dividend for the year ending September 30th, 1905, was declared at the rate of 10 per cent. At the extraordinary general meeting it was decided, in consequence of the great increase of the business, and also for the purpose of carrying through certain further developments contemplated, to substantially increase the capital of the company. Mr. G. H. Smith has been appointed sole director of United Motor Industries, Limited.

The H. F. Process in France.

THERE appears to be a big trade coming forward in France with the H. F. Vulcanizers in the near future. Messrs. Brown Brothers have recently secured the sole rights for France, and their Paris branch, 31, Rue de la Folie Mericourt, has been enlarged, and special facilities for dealing with the new representation have been added. This department is to be carried out upon the same basis as that upon which Messrs. Harvey, Frost and Co., Ltd., have successfully conducted theirs for the past two years, and the policy of co-operation will be followed, and practically the French motoring public will be treated quite as liberally as they would were they dealing with Messrs. Harvey, Frost and Co., Ltd., in England.

THE Motor Exchange of Great Britain, of Boundary Road, Notting Hill, W., notify us that their sale, announced for the 17th inst., has been postponed, owing to the local parliamentary election occurring on the same day.

New Dunlop Depots.

THE Dunlop Pneumatic Tyre Company, Ltd., have recently opened a depôt in Newcastle-on-Tyne at 11, Big Market, and another at 35, Victoria Street, Bristol. Each of these depôts carries a large stock of cycle and motor tyres, as well as a full complement of the Dunlop Company's specialities, including their well-known rubber goods. The opening of these additional depôts has already proved of considerable convenience to the local and district trade in these centres.

THE British Automobile Commercial Syndicate, Ltd., are exhibiting at 97 and 98, Long Acre, prior to their exhibition at the Crystal Palace, one of the 12–16-h.p. ordinary, and one 20–28-h.p. dustless "Exhibition" Spyker chassis from the Paris Salon.

ON Wednesday of last week, the two younger sons of Mr. Harvey Ducros (Messrs. William and George) opened commodious premises, which are to serve as their Irish headquarters, at 17, South King Street, Dublin. These have a street frontage of about 48 feet, with a front to rear measurement of 123 feet, the cubical contents of the building attaining to over 128,000 feet. At the rear of the main showroom are stock rooms, offices, &c., and behind these again is the workshop, the latter being provided with a fine complement of tools, &c. An examination pit, with accommodation for the simultaneous handling of four or five cars, has been installed. Lathes, designed for English and French engine work, are included in the plant. All the accessories of a first-class workshop for dealing with motor repairs are present. A fireproof concrete pit for the safe storage of petrol is provided, and there are excellent facilities for washing cars, &c. Ranged in the showrooms are some of the latest examples of Panhard and Levassor, Mercedes, Swift, and Gladiator cars. The establishment will be in the hands of Mr. W. H. Kingsbury, as manager.

One of the clever paintings which helped to distinguish the Ducros-Mercedes stand at Olympia. The companion picture is given above.

The Pedrail.

Of the usefulness of the Pedrail—or "walking engine"—which we have so fully described in our pages, there can be little doubt, and we are therefore glad to learn that the first stages of experimenting and perfecting this ingenious machine have now resulted in a scheme for placing the inventions of Mr. Diplock upon a commercial footing. To this end, the public are now invited to subscribe capital to Diplock's Patent Traction Engine Haulage Syndicate, Limited, of 61, Marsham Street, Westminster, for £10,000 in ordinary shares. The machine has already been subjected to very drastic tests by the military authorities, and it has had the honour of having a special Local Government Board regulation promulgated entirely for itself. With the capital now asked for, a larger type of engine is to be constructed, suitable for both road transport and ploughing and other agricultural operations in this country. Public experiments, trials and demonstrations will be carried out, and one of the machines will be put into regular daily work on the road between Liverpool and Manchester, where in ordinary work practical evidence of its durability and earning powers will be afforded. The advantages claimed for the Pedrail are a saving in haulage power of 60 to 70 per cent., with a corresponding saving in fuel, a saving of 50 per cent. per annum in repairs, less depreciation, no damage to roads, no vibration or noise, power to cross soft land or lumpy roads with ease and smoothness, and exceptional hill-climbing powers. We wish the company every success in overcoming the many difficulties in dealing with transport upon a big scale. We have the strongest belief that the Pedrail has a very promising future before it.

NEW COMPANIES REGISTERED.

Bolton Mutual Garage Company (Limited).—Capital, £2,000 in £25 shares. First directors, B. P. Dobson, F. G. Hibbert, E. F. Musgrave, T. Scowcroft, F. W. Thompson, and H. Wood.

British Transport Syndicate (Limited), 55 and 56, Bishopsgate Street Within, E.C.—Capital £4,000 in £1 shares. Object, to carry on the business of motor car, omnibus, and cab proprietors, &c.

Chester and North Wales Motor and Garage Company (Limited).—Capital, £5,000 in £10 shares. First directors, Hon. Cecil T. Parker, E. O. W. Davies, and P. G. Wayne.

Commercial Vehicles Construction Company (Limited).—Capital, £10,000 in £1 shares. Object, to carry on the business of motor car, omnibus, and cab proprietors, &c.

De Veulle Variable Speed Gear Company (Limited), 30, Freer Road, Handsworth, Birmingham.—Capital, £500 in £1 shares. Object, to acquire patents relating to a variable speed gear (patent applied for No. 26,051 of 1905). First directors, F. H. de Veulle (managing director), B. G. Hodgson, and J. G. Accles.

East Lancashire and Manchester Carrying Company (Limited), 20, Prudential Buildings, Oldham.—Capital, £20,000 in £1 shares. Object, to carry manufactured goods from the various centres in and around Burnley to Manchester, by means of steam, motor, and horse wagons. First directors, H. Wolstencroft, J. S. Marland, L. Aspinall, J. J. C. Fletcher, and J. T. Dodd.

Motor and Electrical Engineering Company (Leeds), (Limited), North Street Garage, Sheepshanks Yard, North Street, Leeds.—Capital, £5,000 in £1 shares. Object, to acquire the business of a motor car manufacturer and dealer, &c., carried on at the Garage, Sheepshanks Yard, North Street, Leeds, by James Rebecca, as the Motor and Electrical Engineering Company, including the business of an electrical and general engineer recently carried on in Leeds by P. N. Hirst. First directors, James Rebecca, P. N. Hirst, and A. Matthews.

Motor Coach Syndicate (Limited), 62, London Wall, E.C.—Capital, £8,000 in £1 shares. Object, to carry on the business of mechanical engineers, manufacturers of motor cars and wagons, &c., and to adopt an agreement with G. H. Hayes.

Passey and Hall (Limited), Gloucester Road, Ross, Herefordshire.—Capital, £4,000 in £1 shares. Object, to acquire the business of Passey and Bennett, Gloucester Road, Ross, Herefordshire, manufacturers of and dealers in motor cars, cycles, &c. First directors, H. A. E. Passey, J. H. Hall, W. H. Smith.

L. Rene and Co. (Limited), 6, Snow Hill, E.C.—Capital, £8,000 in £1 shares. Object, to carry on the business of manufacturers, vendors, &c., of motors, motor accessories, &c. First directors, T. F. L. Rene, W. Osmond, S. Feast, and F. Best.

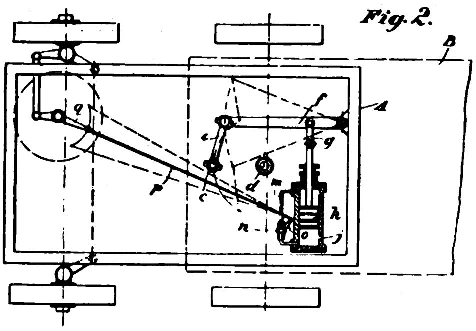
Rugby Motor, Cycle, and Engineering Company (Limited).—Capital, £2,000 in £1 shares. Object, to take over the business of C. P. Spencer, at 47, Park Road, Crouch End, N., carried on as the Rugby Cycle, Motor, and Engineering Works. First directors, C. P. Spencer, W. T. Tucker, and H. G. Alldis.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

19752. 30th September, 1905 Improvements in Road Vehicles. The British Thomson-Houston Company, Limited, 83, Cannon Street E.C. (A communication from the Allgemeine Elektricitäts-Gesellschaft, Schiffbauerdamm 22, Berlin.) This invention relates to vehicles which consist of a front wagon and a rear or trailer portion, coupled together in such a manner that each part may move independently about the coupling pin. In this class of vehicle the trailer has a tendency due to its kinetic energy to turn the front wagon round more than is desired when the vehicle is turning a corner at any speed or deviating from a straight course when descending a steep gradient. The object is to overcome this objection, and for this purpose a liquid pump is employed, and set in action when one portion of the vehicle moves about the coupling pin relatively to the other portion. This pump consists of a cylinder, fitted with a piston, and containing a liquid such as oil. There are two figures. Fig. 2 is a plan of the vehicle. A, is the frame of the front wagon, and B, that of the rear portion or trailer. *c*, is a pin secured to the front portion of the frame of the trailer and adapted to describe an arc of a circle, having the coupling pin, *d*, as a centre when the front wagon moves relatively to the trailer. A link, *e*, is coupled at the one end to the pin, *c*, while its other end is pivotly secured to the one end of a connecting-rod, *f*, which is suitably secured at its other end in the frame, A, of the front wagon. Intermediate the ends of this connecting-rod a link, *g*, is pivoted, the other end of which is connected to piston-rod of piston, *h*, of the liquid pump, *j*. When the piston, *h*, is reciprocated, the liquid contained in the cylinder on one side of the piston is forced through the pipe, *m*, into the cylinder on the other side of the piston. The pipe, *m*, may be made of small bore throughout its length, so as to provide a constant resistance to the flow of the liquid and so prevent a sudden movement of the piston, or it may be provided with an adjustable check-valve, *n*, operated either manually by the driver of the vehicle or by the movement of the vehicle itself through the rod, *p*. The rod, *p*, is connected at one end to the lever, *o*, and at the other end to the lever, *q*, which is directly connected to and operated by the steering gear of the vehicle, so that the area of the fluid passage may be varied according to the deviation o the front wheels of the vehicle.—December 20th, 1905.

Fig. 2.



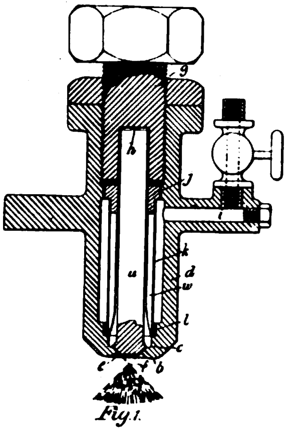


Fig. 1.

27618. 17th December, 1904. Improvements in and relating to Means for Atomising Liquid and Gaseous Fluids. Charles F. de Kierzkowski-Steuart, St. Stephen's Club, Westminster. The objects sought to be attained by the improved atomiser are to effect the atomising of a liquid or gaseous fluid to a greater degree of fineness than hitherto possible, and to mix the fluid with air by means of apparatus which is simple and inexpensive to make accurately, and which is readily taken to pieces for cleaning. In forming the very fine passages for oil, it is necessary that the greatest accuracy should be attained, so that the jets of fluid issuing from the passages may meet accurately and thus be properly broken up at the point of meeting. There are twelve figures. Fig. 1, is a sectional elevation. A coned plug, *a*, fits closely into a coned seat *b*, formed in the inner end, *c*, of a tube or chamber casing, *d*, into which the fluid is pumped under pressure through the passage, *i*, which may be controlled by any suitable valve or cock. The conical suface of the plug, *a*, has formed in it grooves or channels, *e*, preferably V-shaped in cross section, and corresponding in number and passage area to the quantity of fluid required to be passed. These grooves may in certain cases be enlarged gradually in the direction of discharge. The axes of these grooves are inclined to each other and intersect each other at a common point, *f*, in front of the apparatus. The fluid under pressure passing through these channels issues in fine jets, which all impinge at the common intersecting point, *f*, and break one another up into fine particles. The coned plug is held to its seat by a screwed cap, *g*, which may be screwed up so as to bear against the tail, *h*, of the plug, and hold the plug tightly to its seat, whereby no fluid can escape except through the grooves in the plugs. The cap is secured in place and leakage prevented by means of a lock-nut, packing being provided if necessary. A fine meshed wire gauze filter, *k*, fastened to top and bottom rings, *j* and *l*, which fit loosely in the casing, is placed around the stem of the plug. The gauze may be strengthened by the ribs, *w*, secured to it or to one or both of the rings.—December 20th, 1905.

THE PICTURESQUE SIDE OF MOTORING IN IRELAND.—A view at Glendalough; a charming scene in the Emerald Isle. This photograph is a remarkable one, as, beyond the point where the figure is seen standing, the whole of the foreground is really a lake, a fact which at first glance is in no way apparent. The reflections in the photograph are so perfect that until it is carefully studied it is a difficult matter to tell where the lake ends and the land begins. By carefully comparing houses, fences, &c., which are duplicated, the line defining the end of the land and the margin of the lake can be located.

PASSING EVENTS.

The Importance of Figures. We are glad to find that the statistics we published last week of automobile imports and exports of the last few years have attracted, amongst other contemporaries, the attention of the *Financial Times*, which devotes a lengthy and well-considered article to the figures which we then published, and to the conclusions which we drew from them. Our contemporary recognises the importance of these statistics as evidence of the *role* which the automobile industry is now playing in the national commerce, and recognises how fully the statistics have established the claim of the new industry to take rank as one of the most important business spheres with which the activities of the United Kingdom are now concerned. We are particularly pleased to see that a journal of the standing of the *Financial Times*, in the first paragraph of the article, joins with us in issuing a warning against the dangers of present prosperity and satisfactory prospects tending to reproduce a recrudescence of dangerous company promoting, such as nearly wrecked, and for a long time retarded, progress in the early days of the movement. Says the *Financial Times*, "We hope that the pace will not be forced, either as regards the number of miles run per hour or the financing of the manufacturing concerns."

◆ ◆ ◆

The Meaning of a Cold Douche. On one point the *Financial Times* misunderstands us. It quotes our words referring to the hope we expressed that should, in the coming Parliament, anti-motor cranks "make their customary attempts to cripple the growing industry by ill-advised and narrow-minded legislative restrictions, their ravings may receive a suitable cold douche of statistics," and raises the query as to what ravings at St. Stephen's have to do with imports and exports. We are glad to have an opportunity of providing the explanation. What we meant, and what we should have thought was obvious from our words is, that when the aforesaid cranks think fit to air their views in Parliament, the statistics now available, the statistics which we published, and the statistics which the *Financial Times* appreciatively quotes, would be used by those in the House of Commons, who are interested in the welfare of automobilism, to squelch reactionary attempts to injure or interfere with the industry. The way in which the automobilist Members of the House of Commons would employ them as a cold douche, would be simply to point out that an industry which can boast such figures, and claim such importance in the national economy, is not likely to allow itself to be "snuffed out" by legislation if it can help it, and that legislation designed to snuff it out, or seriously injure it, would be proved by the statistics to be absolutely opposed to the interests of the community. Such arguments, if advanced on the basis of the statistics to which we refer, should certainly prove an "anti-spasmodic" to the good people who in the past have been so prone to allow prejudice to outrun discretion where the question of automobilism has been concerned.

More Motor Road. Every week, in fact almost every day, the London to Brighton motor-road project comes up smiling. The persistency and imperviousness to logic and common-sense of the various writers who are advocating it in the Press is reminiscent of Goldsmith's "Village Schoolmaster." Motorists and all the great bodies representing the motor car interest have, with commendable perspicacity, held aloof from it. They have all seen more or less clearly, what the enemies of automobilism saw also from the first, that the proposal provides a splendid argument for those who, like the Rector of Crowhurst, maintain that "our highways were not constructed for motor traffic, and therefore separate motor roads appear a step in the right direction." It should give every automobilist pause that the bitterest enemies of the movement, the people who want to see the motor car improved off the face of our roads, and horse-drawn, donkey-drawn, and nursemaid-drawn vehicles regain their former undisputed sway, are the very people who, next to the promoters of the motor road, wish to see the proposal carried out. If the London to Brighton motor road materialises, and the company does not immediately go into liquidation, other roads will be constructed, and it does not require the eye of a prophet to foresee that when that day dawns the Highways Protection League and all its sympathisers will advocate the protection of the highways, and with some show of reason too, by the confinement of the motor traffic to the motor roads, and its interdiction or limitation to some preposterous rate of progression, such as 5 miles an hour on all the ordinary highways of the country.

◆ ◆ ◆

The Real Question at Issue. We do not propose to consider the points which we have discussed before, as to whether the project is commercially feasible, whether it can ever pay a dividend, or whether automobilists are ever likely to pay at all largely for using it unless their speed on ordinary roads is restricted to an absurdity. The fact is that, from the point of view of the interests of automobilism, it is the suggestion itself that is the thing to be deprecated. That it should, by puff preliminary, puff prospective, pushing, log-rolling, or any other methods of locomotion, be ultimately wheel-barrowed into the House of Commons, is what, in the interests of the movement, we most heartily dread to see. If the proposal ever goes that far, the enemies of automobilism, and the enemies of general road improvement too, will be provided with a two-edged weapon. "See," they will say, "the motorists themselves know that their atrocious vehicles are unfitted for the public roads, and are arranging, or supporting those who are arranging, to build special roads for them." That will be one edge of the weapon! The other edge of the weapon will be this. "Now that the motorists are building, or are preparing to build roads for themselves, let us force them on to them, and off the ordinary highways of the country by reducing the speed limit (on ordinary highways) to such an extent that they will prefer to motor round their back gardens rather than venture out on the highway. Then they will build more motor roads, and there will be still fewer motor cars left on *our* highroads. Then the innocent school-children will be able once more to play at every corner as in the happy days before 1896, the horses of the staid barouche will no more be flustered by the approach of modern locomotion, our main roads will return to their state of idyllic repose (and comparative uselessness to the community), and the only people who will be really sorry will be the police, in whose lives the sport of motor-trapping has recently provided so welcome a relief from monotony!"

◆ ◆ ◆

Monopoly v. Public Interest.

The question is a wider one than even its effect upon the future of the automobile industry, all-important as that undoubtedly is. There are considerations of jurisprudence and public policy, and they are specially suggested by the argument put forward in some quarters in favour of the motor road project, that the railway companies have in the past been allowed to do the same thing to the general benefit of the country and the public. Now the cases are not on all-fours in the slightest degree. It is true that the railway companies have been allowed to build special roads for themselves, and have been allowed to establish restricted monopolies upon them, and consequently to obtain substantial profits on their invested capital, but they have been allowed to do this not merely because they built roads, but because they also provided the rolling stock. To make the cases similar, the proposal should be for a company not merely to build a motor road from London or Croydon to Brighton but to provide motor cars that are specially designed to run on it, and to simply take passengers or produce at a fixed rate. In addition, it must be remembered that the great monopolies which have been permitted to the railway companies and the power to obtain the land required by compulsory purchase, were only granted for certain considerations. The public, as represented by the Board of Trade, has the power to control their affairs and control their tariffs. The State has, for instance, invariably exacted as a *quid pro quo* for the enormous concessions granted, that the companies should run certain services of "Parliamentary" trains at a fixed scale of charges, should supply in addition a certain number of "workmen's trains," and submit to a variety of regulations for the benefit of the public as devised from time to time by the Board of Trade. If a motor road is to be built, it is quite obvious that the company building it will have to be provided with powers of compulsory purchase. What will they have to offer as a consideration to the general public for this great concession — this tremendous inroad on the rights of the private individual? Unless they engage not merely in road building, but in catering for transport and so put themselves on a level with the railway companies, we do not see how they can offer anything at all. And should they do this they will, naturally and quite legitimately, be opposed by the railway companies, of whose *locus standi* in opposing the Bill there could then be no question whatever. In fact, we do not imagine that the proposers of the scheme for a moment grasp, at all fully, what a tremendous departure it would be in English legislation to allow private individuals or a private company to make a great road under compulsory purchase, for the use of privately-owned vehicles, and then to hold a complete monopoly of it. It would, at any rate, be a derogation on the part of the State and its constituent communities of one of its important primary duties. If roads require making because existing roads are inadequate, surely, considering that monopolists could give no real consideration to the public in return, that alone is sufficient to show that undertakings of the kind ought to be carried through by the State for the benefit of everyone.

Registered in Guernsey.

After all these observations on the question, it comes as something of an anti-climax that the company which proposes to build the road, irrespective both of the true interests of the automobile movement and of the general public, and in the teeth of what appears to us to be unanswerable arguments, should be "registered in Guernsey." Companies are usually registered in Guernsey because the comparatively stringent regulations as regards the formation of companies do not apply in that island. It has not been generally regarded as a recommendation in a new company's favour that its registration has taken place in Guernsey. We should certainly be surprised if it proved a recommendation in the eyes of the House of Commons, of any Committee that might be appointed to consider the question, or even of any prospective shareholder in this very questionable project.

◆ ◆ ◆

The Canal Experiment.

The first stage of the long-distance experiment with the suction-producer-gas motor barge, built by Messrs. Thornycroft, has brought to light some very instructive information. The barge is transporting a heavy load consisting of 11 tons of zinc and 4½ tons of coal, towing behind it a "butty" boat loaded with 23 tons of sugar, and reached Birmingham from London *viâ* the Uxbridge and Grand Junction Canals. As far as the reliability, economy, and adaptability to the circumstances of the motor barge was concerned, the experiment has been very successful, and as an example of economy in fuel consumption, it may be mentioned that the 135 miles traversed involved the consumption of only 18 cwt. of coal. Of course, improvements will be made in the future. This is the first attempt to apply a suction-gas motor to canal work in this country, and it has already been demonstrated that the outlook is encouraging. From particulars of the journey which we gather from the excellent account given in the *Standard* by Mr. Thomson, who is in charge of the expedition, probably equally good speed and considerably greater fuel economy would have been obtained under the circumstances with a smaller motor, while a great deal of trouble would have been saved had some other form of propeller—not one of the reversible type—been employed.

◆ ◆ ◆

Some of the Alterations Our Canals Need.

More important still, however, is the undoubted fact, forcibly demonstrated by the experiment, that our canals, as they exist at present, need a good deal of alteration if they are to become great means of transport upon which the advantages of the motor-propelled barge can be fully brought into play. The average speed was singularly slow, not greatly exceeding that of horse-propelled canal boats. It was slow for two reasons, partially because, owing to the shallowness of the canals, even the 24-h.p. motor with the load carried, and the resulting draught, could not get up a high speed, and partly owing to the great delays occasioned by inefficient construction, particularly at the locks. It took the Thornycroft boat no less than six and a half days to make this first part of its 1,000 miles' trip. Most of the existing locks, in fact, are not built for economic or rapid transport, as is evidenced by the fact that on one occasion the motor barge and its "butty" boat were unable to get satisfactorily inside a lock owing to such a ludicrously trivial occurrence as entanglement with a deceased cat. As our canals exist at present, the number of locks is much too great. No less than 159 had to be negotiated in the 135½ miles traversed between London and Birmingham. In most cases a great deal of improvement could be effected by adequate embankment and excavation, though that, of course, involves considerable expense, while if high speeds are to be attained on the straight stretches, that is, between lock and lock, the canals will not only have to be in some places widened but also in most cases considerably deepened. What is needed even more, however, is the more general introduction of up-to-date methods in building the canals, including, for instance, the employment of hydraulic lock-lifts, such as those on some of the great Continental canals, and like the Foxton lifts on the Grand Junction Canal in this country, by which a bunch of barges can be raised from one level to a much higher level at a single operation, and the number of locks in consequence enormously reduced. Canal transport, properly organised, ought to be a very valuable national asset. It is valuable even as it exists at present, for it enables immense quantities of goods, where the time incurred in transport is not a serious consideration, to be transported at very low cost, and it forms the best solution to the difficulty of conveying unusually bulky things from one place to another. But it is quite plain that if canals are to be brought up to modern requirements and to be capable of enabling motor propulsion to exercise its full benefits, large expenditure upon them is urgently required. As motor traction progresses, however, it will become more and more obvious that this expenditure will be ultimately worth incurring, and we may hope in consequence to see it undertaken at an early date on a large scale.

◆ ◆ ◆

The "Direct-Drive" Patent Claims.

It is asserted, on very good authority, that the proprietors of the Renault patent, which claims to confer, as we have already explained on more than one occasion, a monopoly for the use of "direct drive" on live-axle cars, have decided on making a fight of it in this country, and that before very long we shall see the preliminaries of a test action in full swing. A large number of manufacturers, needless to say, will be threatened, though so far we have not heard anything in the nature of threats against private users, such as were freely uttered by the proprietors of the quondam Maybach carburettor patent—a course which we commented on at the time as savouring of hitting below the belt, commercially speaking. But it is useless to deny that in the impending action a very serious menace to a large number of motor car builders is involved. Needless to say, it will be met by organisation of those likely to be affected, and the natural and proper organisation to take up the matter is, it is equally needless to remark, the Society of Motor Manufacturers and Traders. There are indications that the fight will be a thorough one. At any rate, we have reason to believe that the proprietors of the patent have the opinion of the present Lord Justice Moulton (given before his elevation to the Bench) in favour of the validity of the patent. This need not disquiet the threatened manufacturers unduly. In the first place, Lord Justice Moulton, through his long and celebrated career as a barrister, was almost invariably extremely optimistic in regard to the merits of any patent that appeared to him to constitute a genuine invention, and in the second place, as everybody of experience in such matters knows, the opinion of the ablest counsel in such cases is entirely limited by the material put before him. In other words, a search is made by patent agents or solicitors, or both, who are supposed to turn up all the anticipations which they can come across, and it is on these anticipations that the barrister gives his opinion. If the preliminary search has not been a thorough one, the opinion of the greatest patent counsel in the world would naturally be of little value. In this connection it is interesting to remember that the patent which did most to upset the validity of the Maybach carburettor was only unearthed at the last moment, after the results of the regular search had already been placed before counsel.

◆ ◆ ◆

Mainly a Matter of Funds.

All patent litigation, however, is exceedingly expensive, and if the owners of the patent are well provided with funds, and are willing to take matters finally up to the House of Lords, the funds which the united defendants should have at their back should not be far short of £10,000. A case of this magnitude usually costs, where the best barristers and experts are employed on both sides, from £1,000 to £2,000 in the Court of First Instance, from £500 to £600 in the Court of Appeal, and from £3,000 to £5,000 in the House of Lords, and the party that ultimately loses there, if the case is carried so far, has the privilege of paying the lot.

◆ ◆ ◆

Amendment of a Patent —and its Effect.

We also understand that the owners of the patent intend to amend it, in connection with which a point in patent law should prove of interest, viz., that the owner of an amended patent cannot recover either damages or an account of profits for infringement committed before the date on which he amended it. Thus, supposing the patentees were to go into Court now without amending their patent, and win there a test action, they would be able to obtain damages or an account of profits from all manufacturers who had infringed up to the present, while they would also be able to obtain royalties from all manufacturers in future. If, however, they now amend, they would not be able to recover anything for what has been done in the past, and could only enforce their claims from now on, or to be more correct, from the date when their amendment is allowed. Needless to say, all interested parties who have the right to oppose such amendment, are only likely to succeed in their opposition if the proposed amendment is such as would widen the scope of the invention.

⊗ ⊗ ⊗ ⊗

Motor Yeomanry.

THE notion of yeomanry mounted on bicycles will probably excite the scorn or hilarity of a good many old-fashioned officers. But it is a military reform which we are likely to see generally adopted in the near future. At the last reconnaissance held by the South Nottinghamshire Yeomanry, one of the men put in an appearance on a motor bicycle. He justified the indulgence extended to him, for during the manœuvres he proved himself more useful for conveying communications from point to point than a dozen of his horsed comrades. The result is, that instructions have been given that as many as three yeomen per squadron may in future attend mounted on motor bicycles.

THE 1906 SIX-CYLINDER NAPIER CARS.—PART II.

The 60-H.P. Chassis.

QUITE straight, though of tapering cross-section, are the long side-members of the pressed-steel frame, which are largely tied together by the engine and by the gear-box, since both these portions of the driving mechanism are secured rigidly to them at both sides. Otherwise the side-members are only cross-connected at the extreme rear, also just behind the gear-box, and finally by a curved member beneath the radiator through which member passes the starting handle. For lining up the engine and the gear-box true with the frame, metal packing-pieces are first fixed to the inner faces of the side-members, and these are machined up in place by being planed. The engine or the gear-box can thus be removed and replaced without difficulty at any time, and there is no tendency for the frame to be distorted when the bolts by which they are held in position are pulled up quite tightly. At both ends, the side-members are so shaped that they form projecting hangers for the springs.

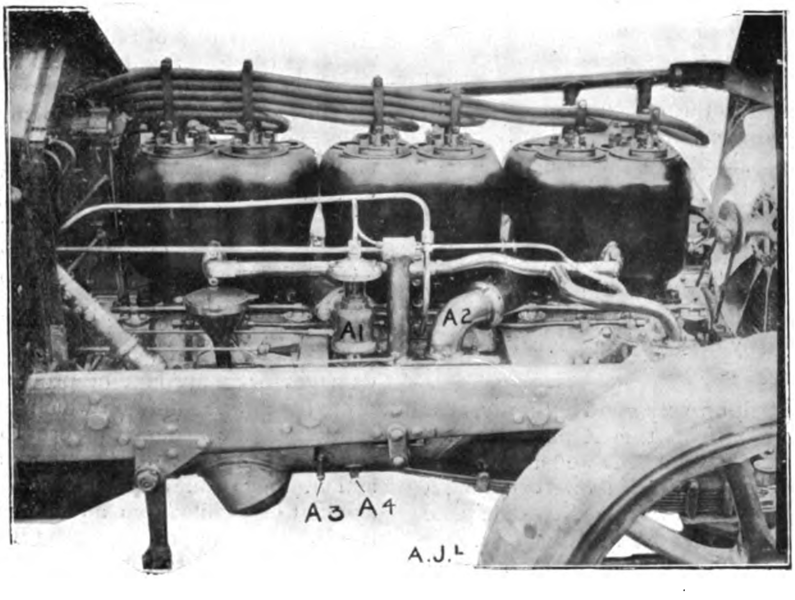

Fig. 1.—The 60-h.p. Napier Car.—View of the 6-cylinder Engine, fixed in place, from the "off" side.

The long semi-elliptic rear springs are fixed above the live-axle, and have shackles at each end, like those on most chain-driven cars; they lie, moreover, outside, instead of beneath, the frame. Radius-rods are also employed for tying the axle-casing to each of the side-members, but the spring-brackets to which they are coupled-up at their rear ends ride quite freely about the axle-tubes; very noticeable, indeed, is the fact that grease-cups are fitted to these spring-brackets, for this emphasises the importance which is attached to this point. Neither the springs nor the radius-rods take the "torque" of the axle-casing, and thus the duty of each is clearly defined; the springs merely take the weight of the body and are free to absorb road-shocks, while the sole function of the radius-rods is to transmit the "drive" from the axle-casing to the frame. The "torque" of the axle-casing is taken by the long tubular casing that surrounds the propeller-shaft and is rigid with the axle-casing.

In front, the semi elliptic springs are provided with shackles at their rear ends, as usual, and these springs lie beneath the side-members. The axle is a curved forging having an **I** cross-section, and the forked portion of each steering-head is formed solid with the short stub-axle that carries the road-wheel. Ball-bearings are used for the road-wheels. Particularly substantial in design is the steering-gear, this being of the screw-and-nut type with a rack-and-pinion between the nut and the rock-shaft. All back-lash between the screw and the nut can easily be taken up, since the nut is formed in two parts; provision is also made for preventing any end-play of the long shaft inside the steering-pillar, this being fitted with adjustable ball-thrust-bearings.

Other characteristic features of this chassis, which are, however, common to all three 6-cylinder models, are the solid aluminium dash-board, the metal sheathing that completely protects the engine, the clutch and the gear-box on the underside, and the large petrol tank which is fixed beneath the frame at the back; the fuel is fed from the tank by pressure, maintained by the exhaust-gases. The foot-brake is provided with a water-cooled drum, and on the 60-h.p. model the brake-band is normally held clear of the drum by a simple tie-bar that passes across from side to side of the frame.

The 60-h.p. Engine.

It is naturally around this large 6-cylinder engine that the chief interest centres, particularly as it differs in many important respects from those built by the Napier firm hitherto. Most marked perhaps is the impression of simplicity which is at once conveyed by it, for its neatness and compactness go a long way towards disguising its real size. And yet every part that is at all liable to require attention has been rendered quite easy of access, since there is no crowding at any one spot. The chief innovations of a radical character include (1) an absolutely automatic system of lubrication which eliminates the ordinary sight-feed fittings on the dashboard (2) a simplified mechanism for operating and timing the standard ignition apparatus, with its high-tension distributor that permits of using a single induction-coil, and (3) the optional provision of a high-tension magneto to afford an auxiliary and entirely distinct ignition system for those who desire it.

In Figs. 1 and 2, this 60-h.p. engine is shown fixed in place in the chassis, Fig. 1 being a view from the "off" side, and Fig. 2 being taken from the "near" side. The engine is, however, also illustrated alone in Fig. 3, which includes four distinct views—one from each side and one from each end. The engine from which Figs. 1 and 2 were taken is not fitted with a magneto, but that shown in Fig. 3 has this auxiliary high-tension system installed upon it.

Referring to these illustrations, it will be seen at a glance that the cylinders are cast in pairs, with all the valves on the same side, that the crank-chamber is formed by two large castings jointed together horizontally through the centre-line of the crank-shaft, that the upper of these two castings is provided with four projecting feet for fixing the engine to each side-member of the main frame, and that there is a large oil-well, A^6, at the bottom of the lower casting for collecting the oil as it flows down from the bearing-surfaces.

Cast solid with the cylinders are the heads, the jackets and the valve-chambers, and above each valve is a screw-threaded inspection-plug. Forming the top of each jacket, however, is a large circular cover plate to which the six-way, branched return-pipe for the cooling water is bolted, while immediately above the hollow, central bolt that holds the cover down in place is a relief cock through which paraffin can be introduced inside the cylinder. The valves are of large diameter, and are kept close up to the cylinder proper, while special care has been taken in the design to facilitate the flow of the gases through the inlet and exhaust passages, and to effectively jacket the valve-chambers. For each pair of cylinders, the two inlet-valves lie between the two exhaust-valves, and thus there is only one induction-pipe connection—but two exhaust pipes—to each casting.

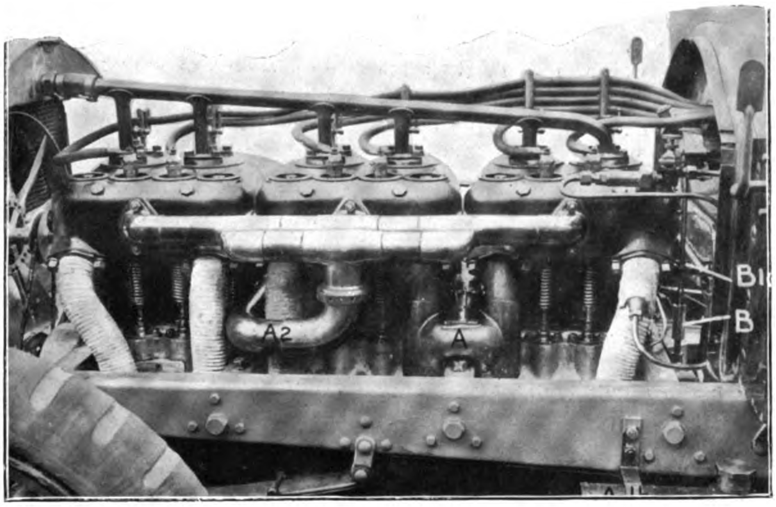

Fig. 2.—The 60-h.p. Napier Car.—The 6-cylinder Engine, as seen from the "near" side of the car.

As with all other parts that can affect the accuracy of synchronism between cylinder and cylinder, special precautions have been taken to ensure that each cylinder shall receive the same quantity of explosive mixture from the carburettor. To this end, the induction-pipe, A^2 — which passes across from the other side of the engine — is provided with double branches (as seen in Figs. 2 and 3) that render the effective distance of the carburettor identical from each inlet-valve. The carburettor draws its main air supply through the pipe, A, from the neighbourhood of two of the exhaust-pipes, the pipe, A, passing across behind the central cylinder-casting in just the same way that the induction-pipe, A^2, passes across in front of that casting. Thus it is that the carburettor is made to occupy a convenient position on the right side, and does not interfere with the accessibility of the valve-gear on the other side.

The cylinders themselves are not only bored out in the usual way, but are finished off dead true in a special grinding machine, which ensures absolute accuracy of their bearing-surfaces, and saves much of the tedious work of bedding in—by driving the engine round prior to complete erection—which has hitherto been a very lengthy process. Similarly also, the pistons, each of which is fitted with three rings, are ground true on an emery grinder, and are therefore rendered strictly interchangeable. The pistons themselves, like the connecting-rods, are remarkable examples of light but strong construction, and it is, of course, largely due to this fact that an engine with a 5-inch bore and 4-inch stroke can run so fast and so sweetly as does this engine. Their shell is very thin, of uniform thickness, and is stiffened up by internal webs, while the connecting-rods, which are circular in section, are bored out from end to end, so that they form tubes having quite a thin wall, and their big-end bearings (with their caps) are quite the lightest which we have yet seen on any such engine. These are, in fact, some of the parts which form the particularly noteworthy features of this engine—moving parts which are extremely costly to manufacture, but enable a considerable reduction of weight to be effected.

Right inside the crank-chamber, running the entire length, and almost immediately beneath the valves, is the cam-shaft, the two spur-wheels for driving it being also enclosed in the chamber. The cam-shaft, with its twelve cams, is made in one solid piece, and the cams are accurately shaped by an automatic machine tool that has been built for this particular purpose; there is thus no risk of a cam becoming loose, nor is there any band fitting that might cause a slight variation in the action of the valves. Beneath the cam-shaft, which (together with its brasses) slides into place from one end of the crank-chamber, a trough is formed in the upper casting of the chamber, this trough being kept full of oil by the overflow from the lubricating system.

The cam-shaft—like the crank-shaft—is supported by four bearings in all, there being two intermediate bearings in addition to those at each end of the crank - chamber. Both ends of the cam - shaft project through the main casing, that in front being fitted with a pulley for driving the fan, and that at the rear having an enclosed worm-gear by which it operates the "commutator" and distributor on the dashboard through the agency of the vertical shaft seen in our illustrations. This vertical shaft now provides a very simple "timing" gear for advancing and retarding the ignition, for inside the socket, B, is a spiral thread that produces a rotary motion between the upper and lower portions of the shaft when the sliding collar, B^1, is raised or lowered by the hand-operated fork that engages with it.

Above each cam is a push-rod with its guide, the guide sliding down into place and being held there by two set-screws. The push-rods are all provided with hardened-steel rollers and with adjustment screws for "setting" the valves. In Fig. 3, it will also be noticed that enclosed gearing is fitted to the crank-chamber, on the left side, in such a way that the cam-shaft is made to drive the lubricating pump, A^7, beneath; of the lubricating system, we shall, however, have more to say presently.

Very long are the four bearings that support the crank-shaft, and each of them is fed with oil from one of the branched pipes that lie alongside the cylinders on the right-hand side of the engine. The shaft itself is made of very special steel—chrome steel—and is not only ground true like most other parts of the engine, but has counterbalance weights to render the running even more steady than it would be without them; it seems curious at first sight that a crank-shaft of this character should benefit appreciably from any counterweights whatever, but the Napier Company are not the only firm who have found them to be a distinct improvement on even multi-cylinder engines. At its front end the shaft carries a sprocket-wheel for driving the water-pump and the centrifugal governor, A^8, and at its other end is a flange coupling to which is bolted the fly-wheel. In Fig. 3 the arrangement of the circulating-pump, the governor, A^8, and the automatically-controlled throttle-valve that forms a part of the carburettor is rendered self-evident, all three being seen to be in line with one another. Fig. 3 also indicates the position that is occupied by the magneto when that auxiliary ignition system is fitted. The magneto itself sits above the water-pump, and is driven by a chain from a second chain-wheel on the pump-spindle.

In any case, however—whether a magneto is employed or not—a safety clutch device is introduced between the pump and its chain-wheel, so that if any obstruction should find its way into the pump the clutch would come into operation and prevent any damage from being done; strictly speaking it is not a clutch that is used, although the effect is equivalent, for the drive is taken through easily renewable pins that would break directly any abnormal strains were imposed upon them.

The carburettor employed is of precisely the same design as that described by us on June 17th last, and it is, therefore, unnecessary to repeat what was then said about it. Its compensating, hand-controlled throttle-valve is coupled up to the smaller of the two hand-levers above the steering-wheel, and its quick-acting throttle-valve is operated solely by the governor. An accelerator-pedal, however, is interconnected with the governor mechanism, and the governor is normally so set that it comes into operation when the car speed is about 20 miles per hour on the top gear. For driving slowly in traffic, therefore, the hand-throttle is usually employed, and the governor is then ready to prevent "racing" under any circumstances that may arise when driving; the driver also knows that the car is not exceeding the legal limit so long as his foot is clear of the accelerator-pedal. In the country, of course, one can either control the speed by hand, keeping the pedal depressed, or can run entirely "on the governor." This double system of control is, as may be judged, particularly convenient and satisfactory.

Other provisions that are made in connection with the carburettor are visible either in Fig. 1 or in Fig. 3, or in both these illustrations. Between the main air supply pipe, A, and the carburettor is the hydraulic regulator, A^1, that is operated from the cooling-water system—by the pressure, and, therefore, in accordance with the speed of the engine—and above the mixing-chamber is an

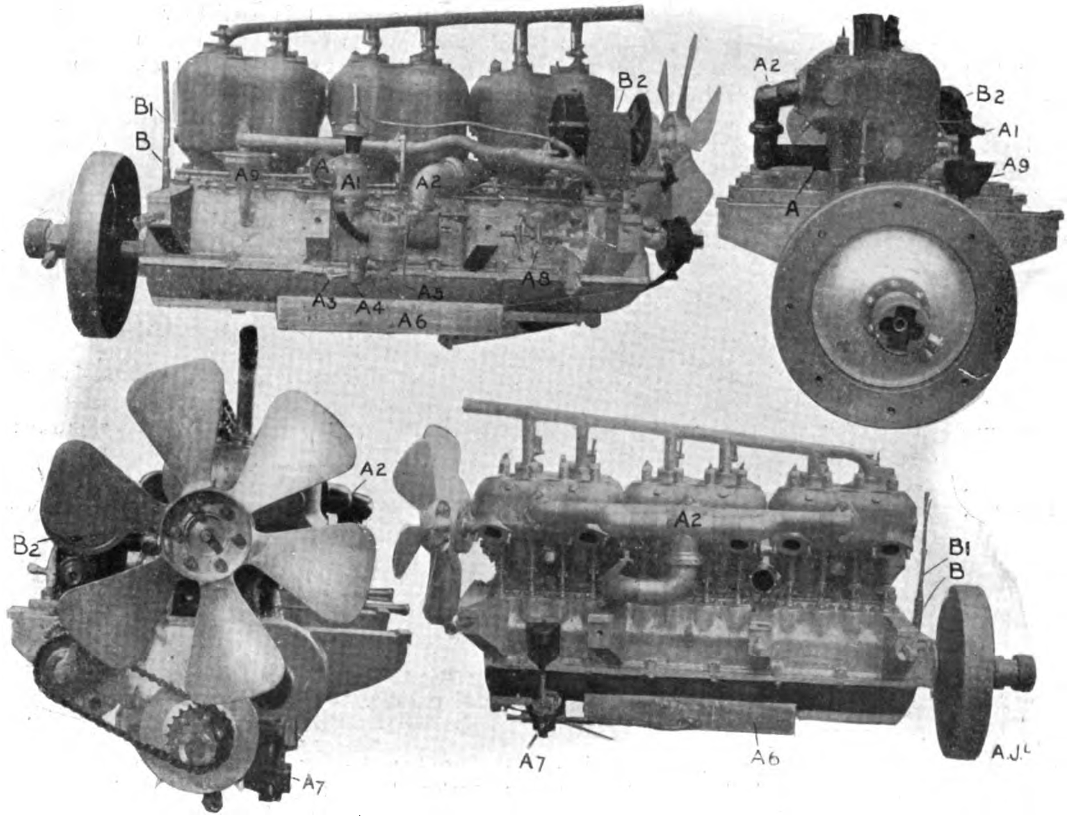

Fig. 3.—Four views of the 60-h.p., 6-cylinder Napier Engine, showing it from each side and from each end. A high-tension magneto, with separate plugs above the exhaust-valves, is fitted to this particular engine as an auxiliary ignition system. The plugs for the usual battery system are similarly placed over the inlet-valves.

auxiliary-air-valve, which can be opened to the required extent by a hand-lever on the dashboard. Very conveniently placed is the carburettor to enable the petrol-cock, A^3, the filter-plug, A^4, and the agitator spindle, A^5 (for "flooding" when necessary) to be got at quite easily, for all these three fittings project through the metal casing that lies beneath the entire mechanism, and can be operated without even raising the bonnet.

Coming now to the lubricating system, which has such a marked effect in saving the driver all trouble and any anxiety, it will be seen that a very large oil-well, A^6, is formed at the bottom of the crank-chamber, and that the pump, A^7, is connected by a short pipe with it. The well can be replenished, whenever necessary, from the large filler, A^9, on the right-hand side of the engine, and this filler is not only large enough to dispense with any additional funnel but has its own gauze-strainer inside it. From the pump, one of the large pipes seen in Fig. 1 leads the oil up into the bottom of a small gauge-glass on the dashboard, while another pipe allows it to pass out again (at the bottom) to the engine. The latter pipe is forked near the carburettor, one arm of the fork leading to a branched pipe that feeds the bearings of the crank-shaft, while the other arm is connected up to a six-way pipe for the cylinders. Each cylinder has a kind of annular trough held in place between it and the crank-chamber, and into this trough dips the piston at the completion of each down-stroke. From the trough, moreover, is a pipe projecting downwards, these pipes directing a stream of oil on to each of the big-end bearings of the connecting-rods, where there is a projecting lip to catch it and direct the oil upon the bearing-surfaces. In the first place, however, the oil is directed upwards by the feed-pipes through which it enters the cylinders, and is therefore injected upon the interior of the piston, and upon the gudgeon-pin. In this manner the oil is circulated continuously, and the driver can yet detect any failure of the pump immediately, if by any remote chance anything should interfere with its action. The gauge-glass on the dash is, of course, completely closed at the upper end, and there is no way in which oil can escape at any point.

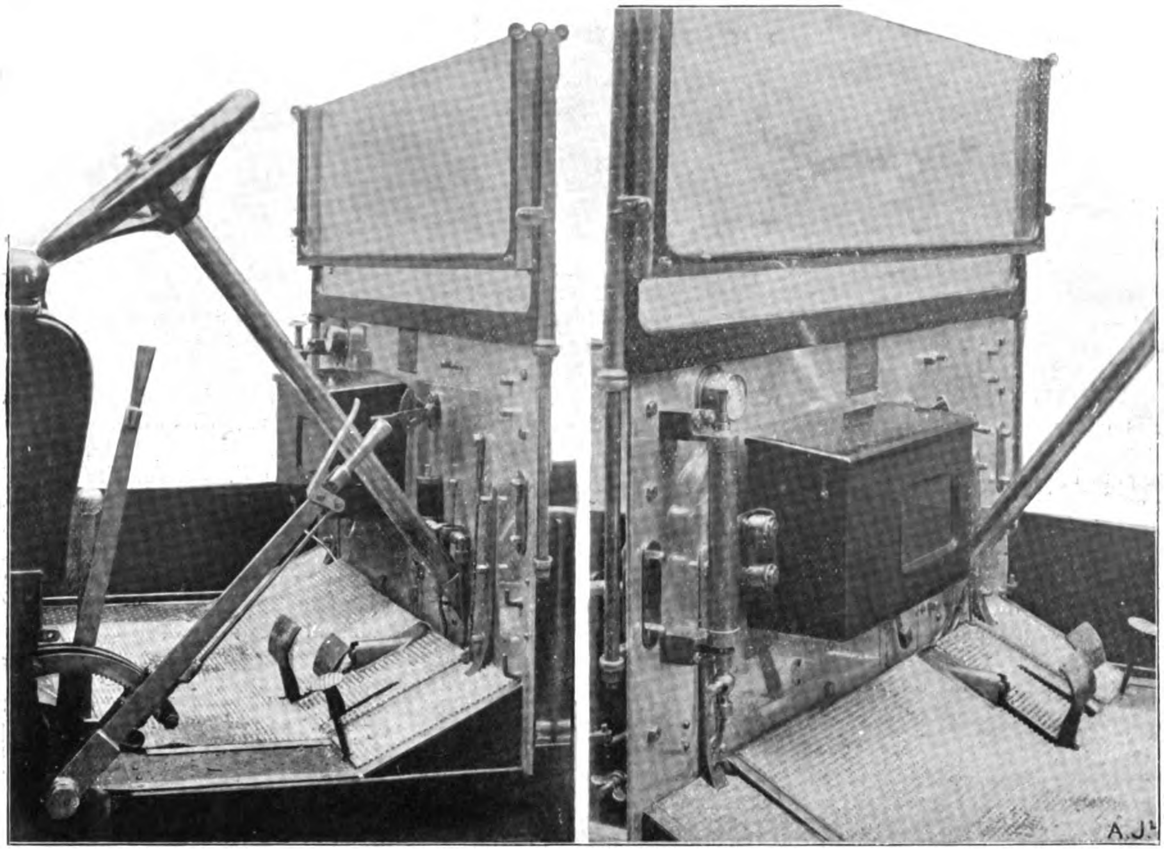

Fig. 3a.—The 60-h.p. Napier Car.—Two views of the dashboard, and of the regulating levers and pedals. On the extreme left is seen the short reversing lever, alongside the change-speed lever and the brake lever, while immediately in front of the driver's seat are the clutch pedal (with its stop), the brake pedal, and the circular accelerator pedal. Centrally placed on the aluminium dash, is the glass-fronted case containing the low-tension commutator, the high-tension distributor and the trembler coil, while to the right of this case are the auxiliary-air lever and the gauge-glass for the lubricating-oil. Beneath the case is the two-way battery-switch, and to the left are fixed the hand-pump for forcing air into the petrol-tank, and the pressure-gauge that is connected to the pressure-feed system. The main switch is fitted centrally above the steering-wheel, the throttle lever and the timing lever working over a quadrant on the wheel.

In Fig. 3A—in the left-hand photograph—this gauge-glass is seen fixed in place, as also are all the other fittings on the dashboard. Above the gauge-glass is the small hand-lever for adjusting the auxiliary-air supply to suit variations of climate or different grades of petrol, and in the right-hand view is seen the hand-pump and pressure-gauge for the fuel-feed system.

(*To be continued.*)

THE G.P.S. PETROL GAUGE.

It is always annoying to have to investigate the contents of a petrol tank by unscrewing the cap and plumbing its depths with a stick in order to ascertain whether there is enough fuel for the projected trip. And yet very few cars are provided with any automatic indication of the petrol level, and remarkably few attempts have been made to introduce any generally adaptable form of gauge. One such—the G.P.S.—has recently come before our notice, however, and this seems to be a *bonâ fide* attempt to supply a useful and reliable commodity. It is extremely simple, as our illustrations show, for it merely consists of a hinged float operating upon a light pointer which moves over a calibrated dial let into the top of the tank. The dial, A, is marked as "full," "½," "¼," and "empty," but the scale could of course be figured in gallons for any particular tank. Projecting down into the tank is a tube, A^1—which is attached to the air-tight case containing the dial—and this holds the spindle, C^1, which carries the pointer, C, at its upper end and the spur-pinion, C^2, at its lower end. Meshing with the pinion, C^2, is the small wheel, B^2, which is connected, as shown, to the rod, C^1, on the end of which is the cork-float, B. As the float rises, it causes the wheel, B^2, to rotate, and this in turn operates, through the pinion, C^2, upon the pointer, thus indicating the level of the petrol on the dial.

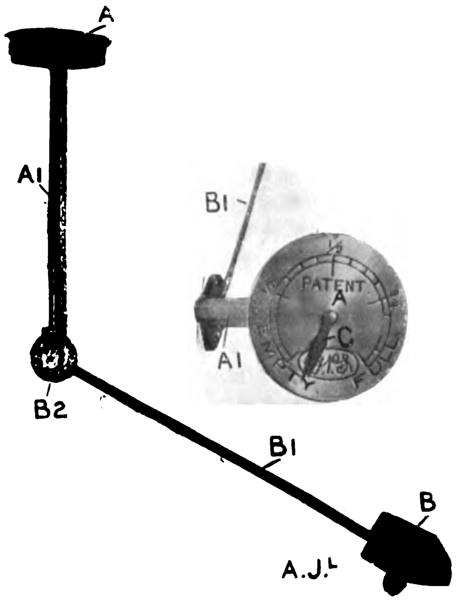

Fig. 1.—The G.P.S. Petrol Gauge. View of the gauge complete, showing the cork float, B. On the right is a view showing the dial, A, with its pointer, C.

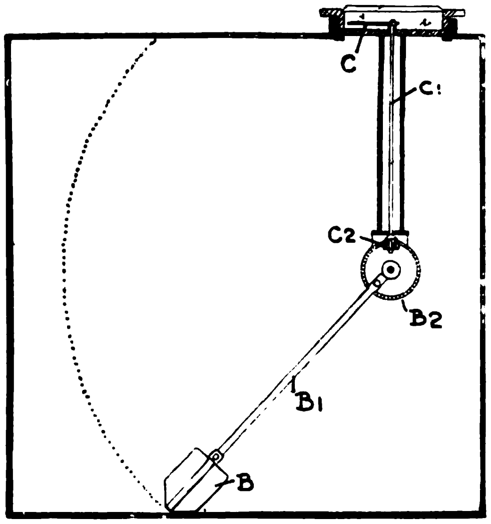

Fig. 2.—The G.P.S. Petrol Gauge. Drawing showing the arrangement of the device in a petrol tank. The dotted line indicates the positions assumed by the float between "empty" and "full."

Except for tanks of a certain shape, the dial should, of course, be specially calibrated, because any given rise of the float does not necessarily represent an equivalent quantity of petrol at all levels in all tanks.

* * * *

Laying the Dust not an Unmixed Blessing.

We referred, not long ago, to the deplorable condition, during the wet weather, of the road at Byfleet, where experiments were made last summer with tar as a dust-preventive. We also pointed out that the piece of road at Cobham, which was similarly treated, was also frequently a cause of considerable trouble to the vehicles negotiating it, though, as a matter of fact, it was not nearly so bad as the Byfleet stretch. Other experiments, it will be remembered, of a similar kind were made near Walton-on-Thames, and there things seem to be now rather worse than either at Cobham or Byfleet, for motor cars traversing the mixture of tar, slime, and mud which indicates the portion of road in the Walton district where the tar was employed, seem to be, in consequence of the greasy surface, but very imperfectly under control indeed. A case was recently heard before the Kingston Bench against Mr. J. Ernest Hutton, for exceeding the speed limit on this stretch of road, the summons being ultimately dismissed, presumably on the ground that it was impossible to attain anything like the alleged speed through the shocking "Slough of Despond" which the tar has there produced. But the Chairman of the Bench, who has hitherto certainly been far from favourable to motor cars, made some very drastic remarks on the danger that was now being caused by stretches of road of this kind. He observed that only a short time ago he had seen a motor car skidding owing to the condition of the road surface (the driver being apparently in no way to blame) in such a manner as to very seriously endanger "a nurse and children in a perambulator." Had the car skidded a little farther, the nurse and the children would in all probability have been killed. Mr. Cockburn added that a serious accident would be certain to take place on these pieces of road before long, unless the whole of the material laid down were taken up. It is very unfortunate that the tar, which was so nice during the hot summer months, has proved such a dismal failure during the wet weather.

THE HOFFMANN BALL-BEARINGS FOR MOTOR CARS.—PART II.

Hubs for Live-axle Cars.

FOR cars of the "live-axle" type, one form of hub is made by which the weight of the vehicle is entirely relieved from the revolving shafts that pass through the stationary axle-casing, and another type is also made for vehicles in which the road wheels are fixed rigidly to the ends of the projecting "live" shafts, and these shafts have to take the "load" as well as the "torque." The former pattern is illustrated in Fig. 4, and the latter in Fig. 5.

Referring to Fig. 4, it will be seen that the tubular stationary portion, F, of the axle projects almost through the hub, and that the inner cone portion, B, of the compound ball bearing is fixed securely round it. The portion, B, is internally tapered near one end to fit up against a conical face on the tube, and a split conical sleeve is forced up against a corresponding face inside the other end, by a screwed and locked nut, as seen. The housing, A, that contains the ball-race-members, D, is formed by the hub itself, and these race-members are, as before, secured in place by the threaded collar, A^3, that is locked by the screw, A^5.

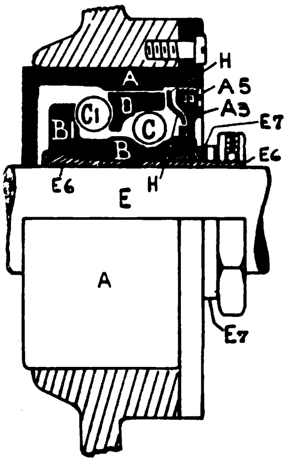

FIG. 6.—Sectional drawing showing the Hoffmann, Single-Compound type of Ball-Bearing.

It will thus be noticed that the ball-bearing is similar to the stationary-axle type, already described, and that it lies in practically the same position in every way. The wheel, however, is driven by the internal "live" shaft, E, by means of an intermediate flexible-coupling-member, E^5, which is held in place over a squared portion, E^2, on the ends of the shaft, by the nut, E^1, and engages, jaw-clutch-fashion, with the hub-casting, A. It will further be noticed that, in this design, the brake-drum, A^6, is made in one piece with the *loose* hub-flange, A^2, and that the entire arrangement is very compact.

Referring to Fig. 5, which is a sectional drawing of the other live-axle type of hub, the upper part is a true cross-section through its centre, and the lower part shows the external portions only in section. In this design, the end of the live-axle, E, passes through the hub, and the external stationary tube, F, that encloses it, terminates in the external shell, F^1, which forms a spherical seating for the ball-bearing. Fixed to the portion, F^1, is also seen the semi-elliptic spring, G, while, beneath it, is the lug, F^4, that receives the usual radius-rod. Similar letters have been used for parts that correspond with those in the other types of hub, although some of these parts differ somewhat in detail. The drawing, taken in conjunction with Figs. 1, 2, and 4, however, clearly demonstrates the precise construction employed.

It will be noticed, in this case, that the bearing is introduced between the revolving axle, E—to which the road wheel is rigidly fixed—and the casing, F^1—that forms a part of the stationary portion of the axle. It will be noticed, too, that the cone, B, of the ball-bearing proper is forced up against a conical shoulder, E^8, on the shaft, E, at the same time that the hub, A^1, of the wheel is locked in place by the nut, E^1. The hub, A^1, itself fits over a square part, E^2, of the axle, but, between it and the cone, B, there is a freely-fitted, split cone, E^4, that has conical faces at each end, and forms a double wedge; in conjunction with the conical shoulder, E^3, the split cone E^4, effectively locks the central portion, B, of the ball-bearing true with the shaft.

In this bearing, the shells, D, fit into a separate housing. A—instead of inside the hub proper—and the collar. A^3, with its locking screw, A^5, are on the outside, instead of the inner side, of it. The casing, A, is moreover mounted so as to be self-aligning inside the other casing, F^1, for there is a spherical socket formed between them, of which the ring, F^2, constitutes the detachable part. The spokes are, of course, bolted, as before, between the fixed flange, A^1—that is formed in conjunction with the brake-drum, A^6—and the loose flange, A^2, into which the dust-proof cap, A^4, is screwed.

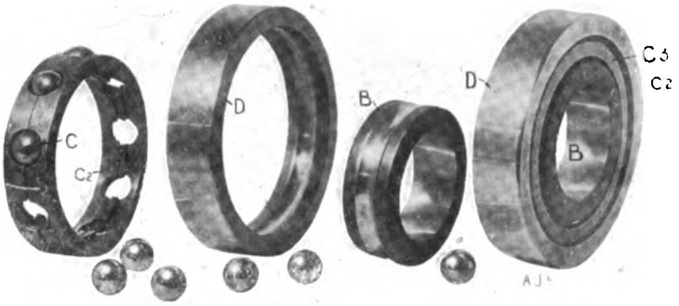

FIG. 7.—Views showing one of the Hoffmann, Single-row, Journal Bearings, complete and in parts.

Other Types of Automobile Bearings.

In certain cases, where two bearings are required on the same shaft, and where the shaft is, moreover, subject to end-thrusts, a type of bearing that has *one* "load-carrying" row of balls and *one* "thrust-taking" row is particularly suitable, and for this purpose the "single-compound" pattern, illustrated in Fig. 6, is manufactured by the Hoffmann Company. The illustration is, for the most part, self-explanatory, in view of our previous descriptions, but special attention should be called to the spring-washer, H, that is introduced between the threaded collar, A^3, and the external race-member, D, that it holds up in place against the balls, C^1, This washer is necessary in order to allow for any expansion or contraction that may take place in the shaft, between the two bearings, and it also compensates for any slight inaccuracy that there may be in fixing the central cone portions of the two bearings the correct distance apart on the shaft.

For use in cases where *no* end-thrust is imposed upon the bearing, a much simpler journal type—having one set of balls only—is employed; the construction of this type is well illustrated in Figs. 7, 8, and 9.

The balls are held apart by a cage, as in the other forms of Hoffmann bearing, and the bearing is made in such a way that the balls can be got into place between the inner and the outer race-members without any kind of "trap-door" arrangement in either race-member, and in spite of both members being solid rings, with their races formed by grooves.

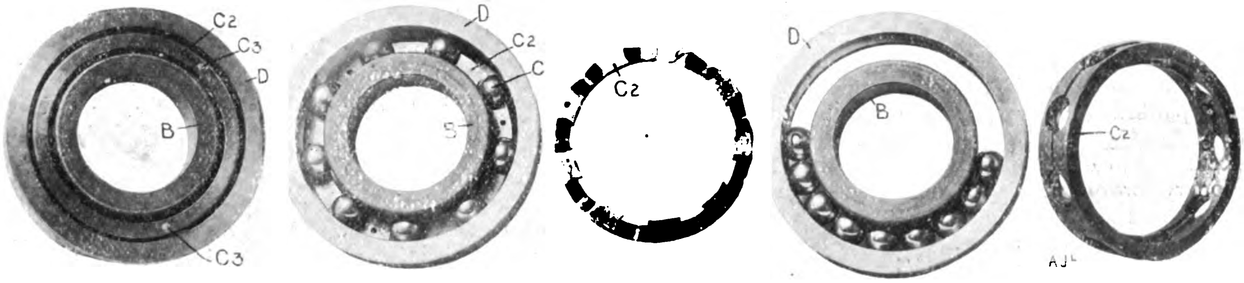

FIG. 8.—Another view of the Hoffmann, Single-row, Journal Bearing, complete and in parts.

In Fig. 7, one of these bearings is seen complete on the extreme right, while to the left of it, successively, are :— the inner race-member, the outer race-member, and the cage. The cage, which is made in two parts, is here seen held together, temporarily, by string passing through the rivet holes, and three of the balls are lying in place in the tapered holes, while the remainder are loose alongside. In Fig. 8 the complete bearing is seen on the left, and the successive views, to the right of it, show it with one half of the cage taken away, show this half-cage separately, show the bearing with the cage entirely removed, and show the cage itself separately, respectively. Fig. 9 is a cross-section, which clearly indicates the shape of the races, and the way in which the balls fit between them. From these illustrations, it will be noticed that although no provision whatever is made for adjustment, the nine balls, C, can be introduced between the inner member, B, and the outer member, D, since they only occupy about a semi-circle, when touching one another, and that the cage —being formed in two pieces—can easily be fitted in place after the balls have been spaced at equal distances apart. The actual faces on the inner and outer race-members are formed by grooves of the shape seen in Fig. 9, so that although the bearing is not intended to withstand any end thrusts, yet it is impossible for any considerable lateral movement to take place between any of the parts. The two halves of the cage, C^2, are subsequently fixed together by the three rivets, C^3, and the cage itself is—as in the other types of Hoffmann bearing, entirely supported and centred by the balls.

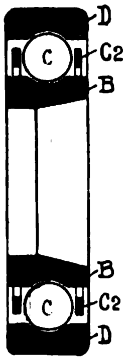

FIG. 9.—Cross Section through the Hoffmann, Single-row, Journal Bearing.

Of the Hoffmann thrust-bearings, comparatively little need be said, since they have been on the market for a considerable period, and also because their construction is in general respects the same as those employed inside the hub-bearings. One of them, however, is shown taken to pieces in Fig. 10, and here it will be noticed that the balls are fitted into the self centring cage, J. The cage is formed by a flat ring, and the retaining holes for the balls are drilled taper, alternately, from the one side and the other. There is a ridge, J^1, on each side of the cage, and this is riveted over sufficiently to prevent the balls from falling out on the side through which they have been subsequently introduced, so that the entire cage with the balls can at any time be removed, and there is no risk of a ball dropping out. The hardened steel thrust collars, J^2— between which the balls run—have the races, J^3, formed by grooves as seen in our illustration, these grooves having a slightly larger curvature than the balls—as in all the other types of bearings.

For fixing the inner race members of any of the "load-carrying" bearings to the shaft, whether it is convenient to machine the shaft specially or not, a variety of forms of construction have been developed by the Company to suit all and every requirement. Where the end of the shaft can be turned with a gradual taper, as in Fig. 3, it is only necessary to tighten the inner cone member, B, up in place by the end nut, E^1, and the bearing is bound to be true. In other cases, a taper is formed partly through the inner member, as seen in Fig. 9, and the bearing can then be fitted over a corresponding taper on the shaft, or a loose, split cone can be forced up between the plain part of the shaft and the bearing, as indicated in Fig. 6; in Fig. 6 there are two loose, split cones, E^6 and E^7, but for some bearings the second one is not needed. In Figs. 4 and 5, other equivalent arrangements are illustrated, the former having a loose, split cone, F^4, forced up by its nut, and the latter having the double-faced conical sleeve, E^4, which is also split, and tightened up by the nut, E^1.

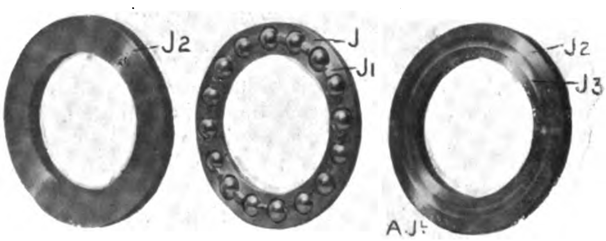

FIG. 10.—View of the Hoffmann Ball-Thrust-Bearing, showing the two Collars that form the Races, and the cage that carries the balls.

Some idea of the various parts of an orthodox petrol car, to which the standard bearings made by the Com-

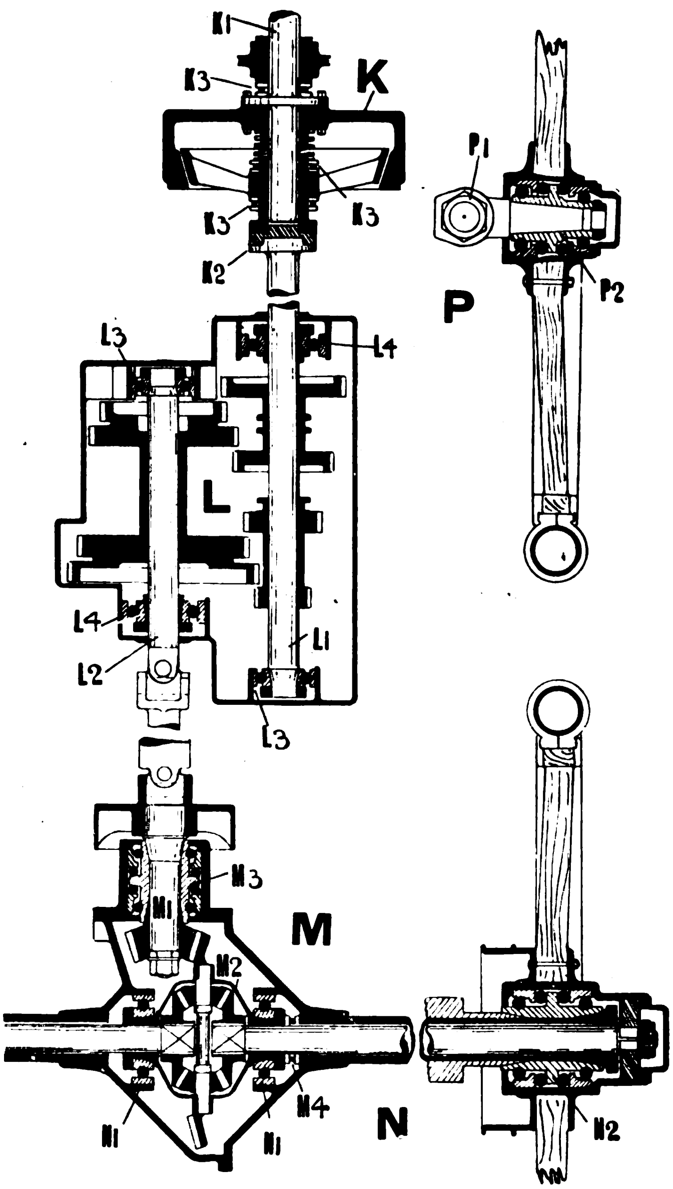

FIG. 11.—Diagrammatic drawing indicating the various types of Ball-Bearing, and the different parts for which they are required, on an ordinary Petrol Car.

pany are applicable, is given in Fig. 11, in which the main clutch, K, the gear-box, L, the bevel-gear, M, the live-rear-axle, N, and one of the front wheels, P, are diagrammatically indicated. For the clutch, K, three thrust-bearings, K^{3}—of the kind illustrated in Fig. 10—are shown, one behind the fly-wheel on the crank-shaft, K^{1}, and the other two on either side of the internal member of the clutch. In this arrangement, a flexible coupling, K^{2}, is supposed to be introduced between the clutch and the first-motion-shaft, L^{1}. The gear-box illustrated is of the type having a first-motion-shaft, L^{1}, and a second-motion-shaft, L^{2}, and it will be seen that both these shafts are fitted with journal bearings of the type illustrated in Figs. 7, 8, and 9; those of the pattern seen in Fig. 6 could, of course, be, to advantage, substituted if required.

The bearing, M^{3}, for the short-shaft, M^{1}—that carries the bevel-pinion driving the differential-gear, M^{2}—is one of the compound bearings, similar to those in the hubs, and the live-rear-axle has load-carrying bearings, N^{1}, of the single-row, journal type on each side of the differential casing, in addition to a thrust-bearing, M^{4}, for taking the end thrust of the bevel-wheel. The bearing, N^{2}, for the driving-wheel is of the type shown in Fig. 4, and the bearing, P^{2}, of the front wheel is of the same pattern as that illustrated in Figs. 1, 2, and 3, this wheel being carried by the stub-axle, P^{2}, that projects from the steering-head, P^{1}.

Some General Considerations.

Although it has been demonstrated beyond all question that they are eminently well suited for motor car construction, there are quite a number of points in connection with the design, manufacture, and use of ball bearings which are of very great importance to ensure their successful employment, particularly when they either have to run at a high rate of speed, or are subjected to heavy loads. First and foremost, special attention may be drawn to the fact that, in the Hoffmann bearings, the load is taken by each ball race at right angles to the axis of rotation of the balls, and that no spinning, or other imperfect rolling action, can therefore take place.

At one time it was the usual practice to design ball bearings in such a way that more than two points of contact were obtained against each ball, and it was also considered necessary that means should be provided for adjusting the inner and the outer races relatively to one another. Experience has shown, however, that it is practically impossible to make the balls run properly (without spinning or skidding) if there are more than two points of contact, and that heating, at high speed and under load, is likely to occur with them. By considering a simple case of a thrust bearing of the four-point ball type, such as that shown diagrammatically in Fig. 12, some of the reasons why four-point ball bearings of all kinds are unsatisfactory can perhaps be most easily explained. In this illustration—which is a section of only one half the bearing—*a*, *b*, indicates the axis of the shaft, and *c* is the central point on that axis from which the lines drawn to *d* and *e* ought, as shown, to pass through the four contact points of the races with the balls. Theoretically, such a bearing as this should work satisfactorily. As a matter of fact, however, it is found in practice that very rapid wear takes place, the reasons apparently being that the "give" in the balls, when in use, causes their track on the race to become a strip of perceptible width, instead of only being a mathematical line, and that apart from this it is practically impossible to grind the races so exactly true as to ensure the four contact points falling precisely on the lines *c*, *d* and *c*, *e*. Another very serious objection—which is also applicable to load carrying, as well as to "thrust," bearings of this character—is that the balls are subjected to compound strains internally, which they are

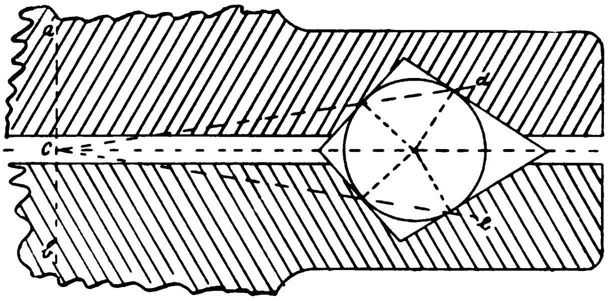

FIG. 12.—Diagram of an old-fashioned Ball-Thrust-Bearing of the Four-Point-Contact Type.

apparently unsuited to withstand. It will be noticed, for instance, in Fig 12, that each race has a wedge action tending to crush the balls, in addition to the other pressure exerted upon them, between race and race.

Although a simple "load-carrying" bearing of the two-point type may be capable of withstanding a certain amount of end-thrust on the shaft, and—from the nature of those made by the Hoffmann Co.—they are capable of doing so, yet it is obviously a questionable practice to utilise them in this way, since the points of contact may then cease to be precisely opposite one another on radial lines from the shaft, and compound strains are also set up (by the wedging action) in the balls. It is for these reasons that the Hoffmann compound bearings have been introduced, and it is, moreover, particularly noticeable in them that the inner rows and the outer rows of balls tend to keep each other true in their respective races, so that there is no undue wear imposed upon the balls by rubbing or chafing against the sides of their tracks.

Of the advantages obtained by the use of proper cages there appears to be but little question, since otherwise the wear and tear caused by the balls rubbing against one another is very perceptible, and it may almost be taken as an axiom that ball-bearings are useless if any wear takes place at all. The cages not only separate the balls in this way, but they also compel all the balls to follow the same track, whether they are actually taking the load at the time or not, apart from the convenience that it is to be able to dismantle a bearing without risk of the balls falling out. The cages themselves do not appear to be subject to any material wear, if properly made, and when designed as they are by the Hoffmann Co., they are automatically rendered self-centring by the balls.

As a result of considerable experience, the Hoffmann Co. recommend the use of a very thick oil in the bearings, but they regard it as a protection from moisture and rust rather than as a lubricant, pure and simple. The cones and shells, which are made of a steel that is specially prepared for the purpose, are annealed and hardened in such a way that the surface is rendered dead hard, but that the interior still remains extremely tough. Needless to state, the success of these bearings is to a great extent due to the accuracy attained by the Company in the manufacture of the balls themselves, since even the best designed bearing would soon be ruined if one single ball were slightly untrue, or were of a different size to the rest; an inaccurate ball would have to take the whole weight, unaided by the others, would damage the races, and, if too large, would render impossible any proper initial adjustment of the bearing.

The 20-h.p. Van.

The 12-16-h.p. Van.

A pair of Milnes-Daimler Royal Mail Vans, which have accomplished respectively 23,000 miles (20-h.p. van), and 30,000 miles (12-16-h.p. van), both of these distances being completed on October 31st, 1905. The former van will complete two years' regular running in April next, and the latter three years in March. The service has been carried out by Mr. G. H. Hayes, of Plumstead, who, as contractor, is running these vehicles for the General Post Office. As will be remembered, we gave particulars in May 1903, upon the occasion of the May Day gathering on the Thames Embankment, of Mr. Hayes's official work for the Post Office. Mr. Hayes informs us that during the entire time these vehicles have been running, the only repair has been one connecting-rod bearing.

THE 4 AND 6-CYLINDER QUESTION.

THAT which is most sought after by engineers whose business it is to construct engines, is—apart altogether from considerations of mechanical detail—the acquisition of even torque. It is this steadiness of turning moment which chiefly characterises the electric motor, and the turbine; and it is this same merit that is being aimed at by those designers who are adopting six, and even eight cylinders, instead of a lesser number, for petrol engines. There is no more satisfactory method of comparing the theoretical advantages, in the matter of torque, between various engines than by graphic diagrams, and those which we have received from Mr. S. F. Edge—that keenest of keen champions of 6-cylinder construction—afford an interesting comparison between single, 4 and 6-cylinder engines.

For the purpose of forming a basis, indicator diagrams were taken from a standard 40-h.p. 6-cylinder Napier engine, and the typical diagram shown in Fig. 1 has been derived from them. The curves show the variations in pressure which take place during the cycle (four

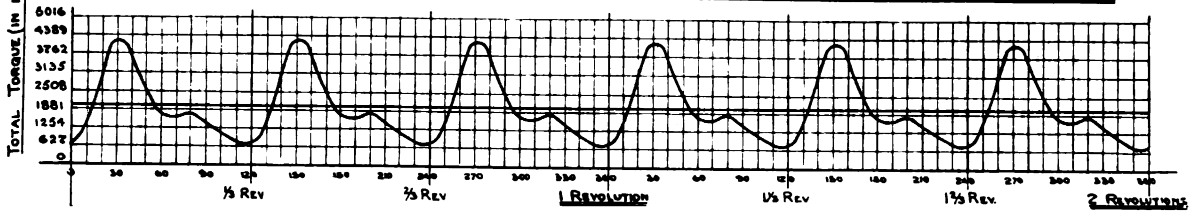

FIG. 4. SIX CYLINDER ENGINE.

Diagrams analysing the relative evenness and intensity of turning moment between 1, 4, and 6-cylinder engines. Fig. 1 is an ordinary indicator diagram which acts as a basis for the torque diagrams in Figs. 2, 3, and 4. Fig. 5 is a summary expressing, in an easily understood graphic form, the results shown in detail in the other figures.

successive strokes) of one cylinder. The suction-stroke is represented by the line, A, slightly below the atmospheric line (14·7 lbs. per sq. in.), it is followed by the compression line, B, which would normally continue to B^2, if ignition—occurring at B^1—did not cause the pressure to rise just before the end of the stroke. Slightly after the piston has passed its dead-centre, the explosion reaches its maximum force of 450 lbs. per sq. in. (absolute), which, on a piston of 4-in. diameter (12·56 sq. ins. area) is approximately equivalent to a blow of nearly 2½ tons. After this the gas expands as the piston travels outward on its working stroke, C, and the burnt gases are finally discharged to atmosphere during the exhaust stroke, D. It has been mentioned that a pressure of nearly 2½ tons is applied to the piston of a 6-cylinder Napier engine when developing 40-h.p., but in a 4-cylinder engine of the same cylinder capacity and stroke this blow would be proportionately greater (nearly 3¾ tons), and in a single-cylinder engine it would reach the enormous value of about 14 tons.

Even when applied to a single-cylinder engine, an ordinary indicator diagram does not convey, except to those who have made a special study of the subject, any lucid idea of the variation of *torque* in the crank-shaft, although it shows the fluctuations of *pressure* behind the piston. This is chiefly due to the fact that the reciprocating parts (chiefly the pistons) are travelling at constantly varying velocities. The result is that they alone require a considerable amount of power to overcome their inertia during the first half of each stroke, and that they similarly transfer an equal amount of power to the crank-shaft, owing to their momentum, during the second half of the stroke. It is, therefore, only at each dead centre, and at approximately midway points between, that the net torque on the crank-shaft is unaffected by them. Their effect has consequently to be added to, or deducted from, that of the varying pressure behind the piston, and this fact entirely alters the comparative aspects of an indicator diagram and a torque curve ; this will be shown more fully presently. It will, of course, be understood that, in practice, the fly-wheel tends to equalise the strains on the transmission shafts on a car, and that it is the fly-wheel which maintains an equal angular velocity of the crank-shaft.

For a single-cylinder engine these changes are graphically illustrated in Fig. 2. All the forces tending to twist the shaft in the "positive" direction are plotted above the zero line, all those which are negative (*i.e.*, which tend to stop the engine) are plotted below the line. These changes take place successively throughout the cycle, and in Fig. 2 they are drawn out in sequence over one long base line, portions of which are marked off to represent equal intervals in the cycle. Similar curves have been drawn, with Fig. 2 as a basis, in Figs. 3 and 4 to represent the torque variations in a 4 and 6-cylinder engine respectively. In Fig. 3 the dotted line represents a 4-cylinder engine having cylinders of the same size as the 6-cylinder shown in Fig. 4, but the full line gives the real comparison since it has been drawn to represent a 4-cylinder engine of the same power.

It is not difficult to understand how these diagrams have been constructed from Fig. 2 as a basis, for the torque of a 4 or a 6-cylinder engine is merely that of an equivalent number of single-cylinder engines superimposed at the correct intervals on the same crank-shaft. Thus the curves in Figs. 3 and 4 have been obtained by superimposing the curve in Fig. 2 upon itself in such a way as to correctly represent the relative firing positions of the individual cylinders in each of those engines. These curves are then "added" together, and only the resultant curves are actually shown in Figs. 3 and 4.

These resultant curves show evenness of torque, but in order to summarise them in a more graphic manner for the benefit of those of our readers who are not interested in the "mathematics" of the subject, we have prepared the simple rectangular diagrams shown in Fig. 5. From these rectangles—which have been constructed entirely from the curves compiled by Mr. Edge—the relative theoretical merits in the matter of torque (between engines of similar power) can be compared, from three distinct points of view, at a glance. The height, E, of each rectangle denotes the relative *un*evenness of the twisting moment in the crank-shaft, and the widths, F, of each rectangle represent the relative time interval elapsing between each periodic impulse. It will be noticed that the rectangle representing the 6-cylinder engine is smaller in both these dimensions, which indicates that the magnitude of the change in torque is less, and that the frequency with which that change takes place is greater—both of which contribute to steady running.

More important, in proportion, than either of these dimensions, however, is the distance, G(+), of the 6-cylinder rectangle above the zero line, because this indicates that the torque is always positive, that there is no dead centre and no need, theoretically, for any fly-wheel in order to keep the engine running. In the case of the 4-cylinder engine it will be noticed that it touches the line, and the theoretical fly-wheel need, therefore, only be infinitely small to enable the engine to run at all, whereas with the single-cylinder engine there is a considerable portion of the diagram, G (–), below the line, which indicates the absolute necessity for a comparatively large fly-wheel.

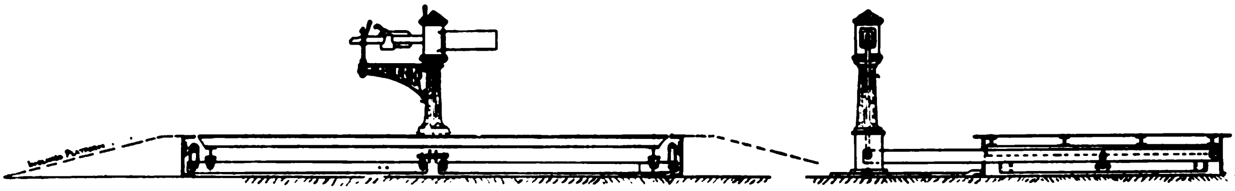
All these points are, of course, discernible in detail in Figs. 2, 3, and 4, but, as we have remarked above, they may not be obvious to the lay mind. One of the most interesting points to be noted is the positive increase in torque which occurs in a 4-cylinder engine during the second third of each stroke. After an explosion the torque naturally falls off rapidly, and owing to the effect of the other pistons it becomes nearly zero after the crank has passed through 60 degrees of revolution. At this point, however, the torque is suddenly increased again — this time by negative work alone — and actually attains a large proportion of its maximum value. This is not due, it must be remembered, to another explosion — which only occurs at the beginning of each stroke — but to the curious effect of the other pistons. It is better understood by considering one or two other interesting points which are very marked in Fig. 2. Thus, instead of the torque remaining reactionary throughout the exhaust stroke, it actually changes over to a forward direction merely because of the momentum of the retarded piston. Similarly with the suction-stroke, which is shown in the first half of the second revolution, the curve crosses the line for the same reason, while even the compression-stroke—which, it would be imagined, should finish with a large reactionary turning effort—hardly indicates any negative torque at all, the momentum of the pistons almost overcoming the compression.

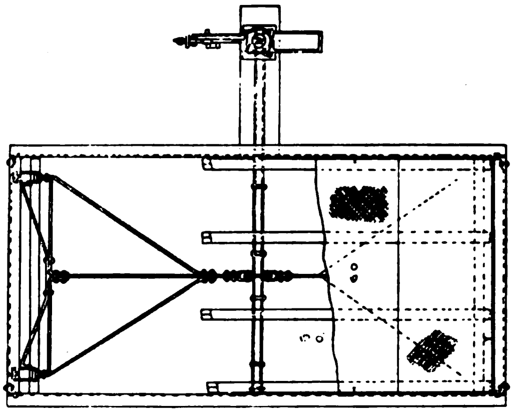
It is the interaction of these effects which produce the interesting—and at first sight surprising—leading feature of the curve in Fig. 3, with its eight apparent impulses, and it is these eight rises of the positive torque that largely explains the known virtues of the 4-cylinder engine.

A SPECIAL WEIGHBRIDGE FOR MOTOR CARS.

Two particularly useful features have been secured in a new weighbridge that the well-known Birmingham firm of weighing machine specialists—Messrs. W. and T. Avery—have recently introduced. It is self-contained, in the sense that it needs no expensive foundations, and can be simply laid down in place anywhere on level ground, and it is so constructed that it is practically portable—can be easily taken to pieces and re-erected by any ordinary workman.

No individual part exceeds 500 lbs. in weight, and yet the steel platform is 12 ft. long by 6 ft. wide, while the machine has a capacity of 5,000 lbs. The working parts are, moreover, completely enclosed, and every part is of ample strength to withstand the maximum strains to which it is likely to be exposed.





Our illustrations give a good general idea of the appearance and construction of this very useful machine, and it will there be noticed that, when erected, the only additional work involved, before it is ready for actual use, is that of building wooden inclined approaches to enable the car to mount the platform; the platform, which is made in five sections, is but 12 inches above the ground, and therefore this is but a very simple matter.

The pedestal is securely fixed to the girder framework and is provided with a self-registering steelyard, which not only enables the weight to be read off by the operator but also prints a permanent record on a ticket at the moment of weighing. Needless to say, this machine is exceptionally well made in every respect, with hardened steel knife-edges and ample bearing-surfaces, and it is almost equally superfluous to add that each weighbridge is most carefully calibrated, and is tested to its full capacity, before leaving the works.

For use in connection with automobile contests of all kinds, such a machine is unquestionably a great improvement over many of the rough-and-ready devices that have been resorted to on certain occasions of this nature in the past, and we have no doubt that there are many other instances in which motorists will find such a machine invaluable.

* * * *

AERONAUTICS.

Deutsch-Archdeacon Competition.

THE rules for the Deutsch-Archdeacon "Heavier-than-Air" Competition, to which we referred on October 8th, 1904, when the Prize was first offered, comprise the following stipulations :—

1. Any type or size of apparatus may compete, provided it does not rely for its suspension on any gas which is lighter than air, nor have any material connection with the ground during its flight.
2. Those desiring to make a trial must notify the Aero Club de France.
3. Each entrant must send a fee of fifty francs before he makes his trial. The entry fee is not returnable ; it covers all trials made by the entrant during one day only.
4. Notification of a trial must be made in time for the Aero Club officials to be advised on the previous evening at latest. Should the trial ground be far distant from Paris the notification must be sent in earlier than this.
5. Trials will be only recorded between sunrise and sunset.
6. The committee reserve the right of refusing to officially observe a trial if the *bona fides* submitted to them are not considered to give sufficient evidence of extensive private experiments. On this point their decision is final.
7. Only one entrant may make trials during one day. If there are more entries, the others must compete on successive days, following the first.
8. Entrants must specify the starting and turning points, which must be separated by at least 500 metres.
9. Trials must be held in France, and if conducted outside a radius of 40 kiloms. of Paris the competitor must bear the expenses of the official observers.
10. Trials may only take place in the presence of the club officials. The "start" will be considered to occur when the machine ceases to touch the ground. If the experimenter does not wish to alight on returning, he must drop some object on the ground within a radius of 25 metres of his starting point.
11. The club officials may take any steps for the general safety, but are, nevertheless, not responsible for accidents.
12. The Prize may be competed for within 5 years from 1st October, 1904.

A Letter from the Wright Brothers.

THE rumour to which we referred last week, that a French syndicate, represented in the United States by Mr. Arnold Fordyce, had concluded an agreement with the Wright Brothers for the purchase of their invention and their first machine, appears to be well founded. The negotiations have apparently been concluded, and both Wilbur and Orville Wright have written to M. F. S. Lahm, of the Aero Club de France, the following letter :—

"We have received your last letters, for which we thank you. We have just signed a contract with Mr. Arnold Fordyce, representing various personages in Paris, to give the option to purchase our first machine for the French Army. We have received a letter from the management of the 'National Society of Commerce' of another European country, which, having heard of our offer to sell to the French Government for a million, is anxious to acquire an option, on the apparatus, being anxious to present the apparatus to its Emperor on the occasion of a National *fête* at an early date. Our French contract prevents us from giving an exclusive option at once.

"Our motor is very satisfactory as regards regularity and power, but weighs considerably more than the French motors of the same output. Still we shall be able to double the weight of our motor without experiencing any difficulty in flight. We have never made any particular attempt to attain extreme lightness, neither as regards the motor or to the other fittings, but we have directed our efforts towards obtaining solidity and the highest possible 'efficiency.' It is proved that we have been able to alight over and over again without the slightest injury to our apparatus. We think our motor is fairly efficient, as it consumes less than a pound of gasolene per horse-power hour. We have not as yet formed any views regarding its commercial exploitation, because we hope to be sufficiently remunerated without doing so."

Thus it would seem that the French Army is to reap the first benefits of the Wrights' ingenuity and pluck. It will not be altogether creditable to the United States if this proves to be so, but perhaps the historian will look upon it as a return for favours bestowed in the past. America largely owed its independence to Lafayette, and the Irish regiments in the French service. That it is returning past benefits by thus placing its most recent discovery at the military service of France, will, after all, only be a *quid pro quo.*

Santos Dumont Adopts the Aeroplanes.

AMONG the secondary results of the revelations which have been extorted from the Wright Brothers, may be counted the decision M. Santos Dumont has embraced with some suddenness of, if not abandoning the navigable balloon type of airship, betaking himself to experiments with machines of the aeroplane type. We understand that he is already having a machine built to compete for the Deutsch-Archdeacon Prize, which, however, is not at all like that used by the Wright Brothers, as it is understood to be furnished with two vertically-acting propellers on the top, which perform the lifting functions, while a horizontal propeller in front is to produce motion in the forward direction, the gyrations of the machine being regulated by a suitable tail. So far, we do not gather that any actual experiment with a machine of this type has been made, and opinions, to say the least, differ as to the value of the vertical propellers as soon as forward motion has commenced. However, we shall see what we shall see, and in the meantime the suggestion, together with the proposal for the Polar expedition, effectively keeps M. Santos Dumont before the public of Paris and the world generally.

Are His Proposals justified by Experience?

THIS announcement of the determination of M. Santos Dumont to accomplish the conquest of the air *and* the Deutsch-Archdeacon Prize at one swoop by means of a "helicopterous" flying machine, has excited considerable attention among several French aeronauts, by some of whom it has apparently been taken quite seriously. An example is provided by M. Archdeacon, who expresses himself as very sorry to learn that M. Santos Dumont seriously proposes to adopt the helicopterous arrangement rather than the aeroplane which, in M. Archdeacon's opinion, provides much the best chances of success. The term *helicoptere* has been employed to designate a type of flying machine appearing in the patent records of most European countries, in which reliance is placed on vertical-lifting propellers revolving in a horizontal plane to provide the ascensional force. M. Archdeacon points out that the efficiency of propellers arranged in this way as regards lifting — though lifting can be apparently effected by their means if sufficient power is put into them—is extremely bad, and that the stability of a machine when proceeding to move through the air fitted in this way is more than problematic. In addition, the extra motive power, the provision of extra propellers that are necessary on the helicopterous principle, and the transmission mechanism to them, all involve great increases of weight as compared with the motor-driven simple aeroplane. M. Archdeacon has gone through a number of calculations as to the minimum safe weight for all these appliances, and he differs a good deal in his results from M. Santos Dumont. While the maximum weight which M. Santos Dumont calculates his machine, including the aeronaut, will amount to is 160 kilogs., M. Archdeacon reckons 212 kilogs. as the minimum possible if the machine is to hold together. As the calculated ascensional force which the arrangement of propellers and motor of M. Santos Dumont is proposing amounts altogether to 180 kilogs., if M. Archdeacon's calculations are correct the machine will fail to rise in the air owing to an excess of its weight over its lifting power of some 32 kilogs. Upon the whole we are inclined to agree with M. Archdeacon. We do not say that M. Santos Dumont will not effect something. What he will effect the future alone can show. But we simply do not believe in the lifting propeller principle, one among our many reasons being that forcibly advanced by M. Archdeacon, that the stability of such an arrangement is highly questionable, no means for restoring equilibrium, if it is once upset, being apparent. In addition to this, no one knows in the least what effect advancing forward through the atmosphere will have upon the lifting power, torque, and other characteristics of the lifting propellers. It seems at any rate quite certain that the surface they cover cannot be looked upon in the same way as an equivalent surface of aeroplane. M. Archdeacon points out, and it is a tremendously trenchant observation, that there is a substantial agreement in design between all the machines that have really raised themselves from the ground and flown any distance, either with or without an aeronaut. They have all relied upon surfaces to sustain them in the air, propellers merely to push them forward, and on the vertical component produced by the action of the air encountered by the aeroplane, for vertical lift in the air; mechanically, at any rate, this would seem to be far the most efficient method to adopt. We make these observations simply because we believe that where the experience obtained by experimenters working quite independently of one another all converges towards the same conclusion, it is a conclusion which at any rate is entitled to the highest respect. Of course, nobody can really foresee what genius and determination will effect, and none will be more ready than ourselves to congratulate M. Santos-Dumont should he succeed in proving that the methods adopted hitherto of tackling the problem are not the only ones which can lead to success; at present, however, all the indications seem to point in the opposite direction. That the aeroplane has the power to lift itself, and, according to its size, one or more operators as well, has been proved to the hilt. It is controlling and managing it that present the difficulty, and constitute the appeal which it makes to the element of skill. It is impossible to avoid the misgiving that those who pin their faith on the lifting propeller do so rather because they feel that there is something that will hold them up no matter what happens. Vertical propellers, in fact, represent to them the gas-bag of the navigable balloon. . . . But, where is the security if the motor should stop suddenly?

A Holland Idea.

M. SANTOS DUMONT'S change of attitude is not the only strange result which the publication of the Wright Brothers' performances has produced. It is reported by a London morning paper that Mr. J. P. Holland, known as an inventor of submarine boats, who has previously declared his interest in aeronautical problems, has undertaken to fly from his office in New York to his residence in New Jersey in March next. The details furnished in regard to the machine he proposes to use are calculated to excite the hilarity of those who have studied the subject even superficially. Mr. Holland proposes, it is stated, to employ four silken wings 20 inches long and 18 inches wide at the tip. They are to be worked by foot pedals like an ordinary bicycle, presumably by a chain drive. If wings of these dimensions are capable of raising Mr. Holland in the atmosphere, he must be a more than usually ethereally constructed inventor. Needless to say such a machine would be absolutely inadequate as a Pegasus for even the flimsiest poet of the Postlethwaite school. We are reluctantly forced to the conclusion either that Mr. Holland has been having some fun with the reporters, or that the reporters have been having some fun with him.

An Aerial "Bicycle."

AMONG the many alleged inventors of new flying machines, "there is another Richmond in the field," with an arrangement which appears to somewhat resemble that of Mr. Submarine-boat Holland. The motive power is to be provided in much the same way by treadles worked by the aeronaut (not necessarily the inventor). Of course, bamboo, aluminium, and silk are the main substances employed, and the machine is ridden down an inclined road till it attains the necessary impetus to soar up into the air. A clutch, we are then informed, comes into play. Whether this means that the aeronaut clutches for the ground to steady himself, or not, is not explained, and the machine, we are told, is driven with about the same amount of exertion as is involved in riding an ordinary bicycle, an amount which, as most people will be willing to admit, varies considerably. No data, disputed or otherwise, are to hand as to what this inventor has actually accomplished.

More Encouragement for Aeronauts.

BY way of inspiring further efforts on the part of aeronautical inventors, M. Deutsch de la Meurthe has announced a new competition, under the auspices of the Aero Club of France, endowed with valuable prizes. The following are the conditions of his offer:—

1. The prize may be competed for with machines either heavier or lighter than air.
2. The circuit will be a minimum of 200 kiloms., with a turning point, designated in advance, distant 100 kiloms from the start.
3. The prize itself will be a trophy valued at 10,000 francs. The winning club will be holder.
4. In addition, a money prize of 20,000 francs will be given to each of the three first competitors who win the Cup; for which the trials will be annual.
5. The detailed rules will be drawn up later by the Aero Club de France in consultation with M. Deutsch de la Meurthe.

A Military "Flyer."

CAPTAIN FERBER, of the French Army, is likely to be a competitor for the Deutsch-Archdeacon Prize for heavier than air machines.

* * * *

CLUBS AND ASSOCIATIONS.

A.C.G.B.I.

THE annual general meeting of the Automobile Club takes place on March 8th at the Club House, 119, Piccadilly.

Marine Motor Association.

AT a Council meeting, held on the 11th inst., Mr. J. I. Thornycroft's proposal that a fixed piston speed be assumed, instead of revolutions, in motor power calculations, was further discussed. Mr. F. R. S. Bircham submitted figures obtained from measurements taken last year, and owing to the variations in these, it was felt that it would be impossible to assume a fixed piston speed which would be fair to all motor builders.

Mr. Linton Hope's resignation of the honorary secretaryship was accepted with regret, and he was elected to a vacancy on the Council.

Motor Yacht Club.

THIS organisation has published a somewhat lengthy *resumé* of its year's work. Over one-third of the whole article is a verbatim extract from the judges' report on the Reliability Trials, which we published at the time of its issue, and the remainder enumerates in somewhat less detail the other events of the season.

Yorkshire A.C.

THE annual meeting of the club takes place on January 26th at 8 p.m., in the G.N. Hotel, Leeds, the club headquarters. A special general meeting, convened for the purpose of dealing with the affiliation question, will precede the annual gathering at 7 p.m.

Free Admission to Exhibitions for Motor Union Members.

MEMBERS of the Motor Union will be admitted free of charge, on production of their Motor Union tickets of membership for 1906, to the following Motor Car Exhibitions:—

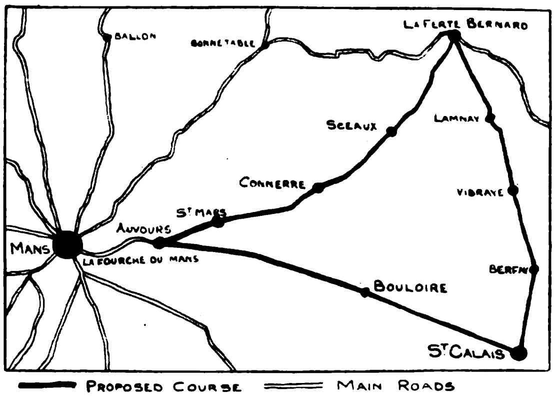
Birmingham (Bingley Hall), January 19th to 23rd.
Newcastle (new Exhibition Hall), February 9th to 17th.
Manchester (St. James's Hall), February 23rd to March 3rd.
Glasgow (Exhibition Hall), March 9th to 17th.

The Motor Union ticket of membership is, in effect, a season ticket for these important provincial Exhibitions, and may be utilised as frequently as the holder thereof may desire to visit them.

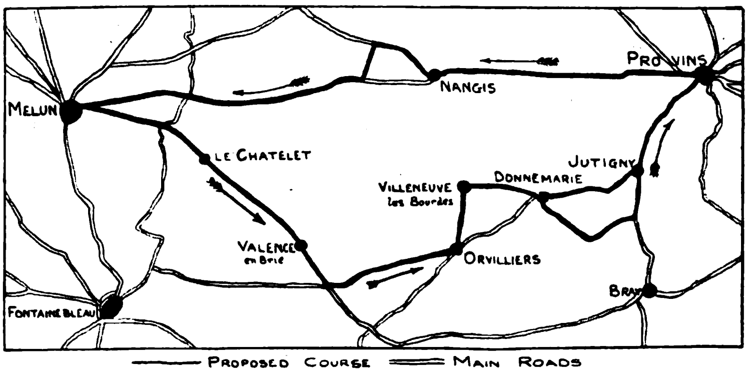
Radiators for Petrol Cars.

IN a very comprehensive paper on the subject of radiators for motor cars, read before the Institution of Mechanical Engineers (Graduates' Association) on Monday of last week, Mr. F. E. Bennett gave some interesting figures. Speaking of radiators of the finned tube type, he stated that 3 sq ft. of cooling surface per h.p. was about the usual allowance on petrol cars to-day when a fan is used in connection with them, or about twice that surface with no fan. The surface of the fins should, he thought, be at least four times, but not more than six times, that of the tubes themselves. Speaking of the reduction of temperature effected in an ordinary radiator, he had found that the temperature of the water was lowered by about 30 degrees to 50 degrees F., and on the subject of the quantity of water passed through the system per h.p. developed, he mentioned 10 to 15 galls. per hour as being the customary limits. As regards the quantity of heat taken up by the jacket from the cylinders, he fixed from 25 to 35 per cent. of the total heat available as being approximately the usual figure. The greater portion of the paper was occupied in reviewing the various types and systems in use, and in a consideration of many of the constructional points connected with their manufacture.

RACES, RECORDS, AND TRIALS.



The Sarthe Circuit.—The Selected Course.



The Brie Circuit.—The Second Favourite.

"GRAND PRIX" RACE OF THE A.C. DE FRANCE.

The 1906 Scottish Reliability Trial.

THE Scottish Reliability Trial, organised by the Western Section of the Scottish Automobile Club, has now been definitely fixed to take place on 13th, 14th, 15th, and 16th June next. There will be some variation on last year's route, which it is thought will extend the interest and value of the Trial. It is proposed that a portion of the south of Scotland will be included, and that the classification on this occasion shall be by price.

The Grand Prix Course.

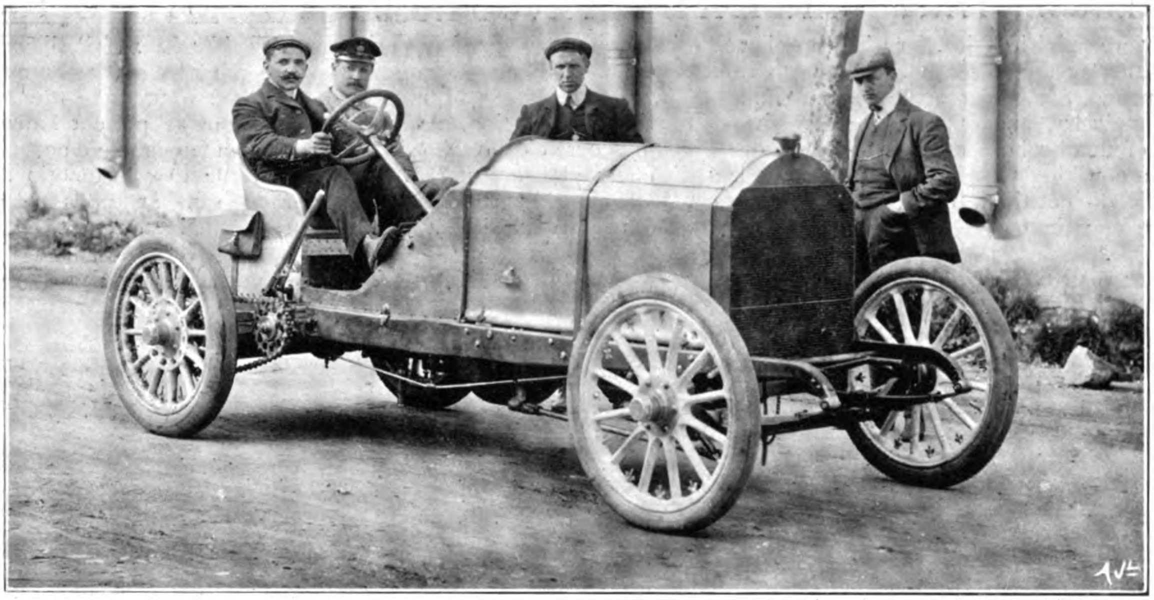
ONE by one the numerous courses suggested for the big French race have been voted unsuitable by the A.C. de France Sporting Commission. The only two left in the balance last week were the Sarthe and the Brie Circuits given above. The former is near Le Mans and is about 100 kiloms. in length. It forms an almost perfect equilateral triangle between the points La Ferté-Bernard, Auvours and Saint-Calais. The latter is triangular in character, but is somewhat irregular on two of its sides. Last week we gave the extreme points of this, starting from Melun. The variations suggested were to branch off to the left, short of Montereau, to Orvilliers, and then go north to Villeneuve and on to Donnemarie, Jutigny, and Provins, *viâ* Longueville, thence, as before, back to Melun.

The final decision was taken on Tuesday, when the Sarthe Circuit was the one selected. Many points in its favour have turned the balance. It is within three hours of Paris, and very convenient for railway service at several points. There is only one level crossing, viz., at St. Calais, and of the 100 kiloms. 80 are practically straight roads. Finally, the town of Mans is contributing 100,000 francs to the organising fund. The lengths of the three sides of the triangle are:—La Fourche—St. Calais, 34 kiloms.; St. Calais—Ferté Bernard, 31½ kiloms.; Ferté Bernard—La Fourche, 34½ kiloms. One of the suggested points for the start is at La Fourche, another near Ferté Bernard.

An important innovation is recommended by the Sporting Commission, in accordance with our statement last week, viz., *that the race shall extend over two days*—probably about 600 kiloms. per day—with the right to change conductors on the second day. This recommendation is mainly in view of the nature of the circuit, which will give exceptional opportunities for high speed, and by reason of the new rule permitting only the driver and mechanician to change and repair tyres. Three only were against the two days' proposition, viz., MM. Loysel de Turckheim and Brasier. Of course, the final decision rests with the A.C. de France Committee, where no doubt the matter will be again thrashed out strenuously.

Ormond-Daytona Beach Meeting.

COMMENCING on Monday next, this annual Florida race meeting will be continued during the whole of the week. A splendid programme of events has been arranged, and we anticipate further sweeping successes from Clifford Earp and his 6-cylinder racing Napier, the only British racing car taking part in the races. Wonderful stories are flying around in regard to a new machine which has been secretly constructed in America for Mr. A. G. Vanderbilt. The h.p. of this monster is given variously at 125 to about 500-h.p., and such "gentle" speeds as 150 miles per hour are confidently mentioned. As we announced months ago, Sartori, the clever Italian driver, has been selected to drive this machine. Many of the leading crack Continental cars, which have all manner of "records" to their credit, are amongst the entrants, and we may therefore expect to have some startling speed announcements cabled during the coming week. Hemery, whose marvellous achievement on the Ostend road on a 200-h.p. 8-cylinder Darracq racer we recently recorded, will be present to uphold his world's record. In addition to the 8-cylinder car, three other racers have been shipped for the Florida Meeting, including the 80-h.p. Darracq which successfully carried Hemery to victory in the Circuit des Ardennes and Vanderbilt Cup races, the Darracq Voiture Légère and the Voiturette. The Darracq Company will therefore be competing in the three classes—heavy weight, middle weight, and light weight, as they are termed in America. It was at first thought, we are informed, that these cars would be unable to compete at the Florida Meeting owing to the North German Lloyd Steamship Company, after almost promising to take the cars by their ss. "Kaiser Wilhelm II.," cabling at the last moment that they were unable to accept them. The Darracq Company, it appears, had offered this line a big sum if they would allow the "Kaiser" to open her hatches and pick up the cars at Cherbourg or Southampton, these ports being reserved for passengers only



An interesting picture of the three well-known racing drivers, Messrs. Gabriel, Duray, and Rougier, who have all been "annexed" for this year's racing by Baron de Turckheim, head of the De Dietrich firm. The De Dietrich Company are taking a prominent part in the big events of 1906, including the A.C. de France "Grand Prix," the Targa Florio, the Brescia and Ardennes Circuits, and the Vanderbilt Cup. The car in our photograph is a 120-h.p. De Dietrich racer; Gabriel is at the wheel, Duray is in the background, and Rougier is by the front wheel.

on this line. However, by cabling to America and securing a special express train for the cars and men from New York to Florida—a trip that takes two and a half days, and will cost £400—it was found possible to bring the cars through England and ship by the ss. "Majestic" from Liverpool. This will enable the racers, it is hoped, to arrive at Florida the day before the meeting commences. As the Darracq Company say, this does not leave much time to tune up their cars, which will have been at the mercy of the wind and waves of the stormy Atlantic for six days.

An Illustrated Racing Calendar.

It is proposed by the A.C. de France to issue annually an illustrated calendar of sporting events, which is to be sold at two francs a copy. Each notification of a meeting to the A.C. de France, must be, it is suggested, accompanied by a deposit of, for the first event, 500 francs, for the second, by the same organisers, 300 francs, and 100 francs per meeting for any further events. These deposits will remain as a charge against the sale receipts for the books when published.

* * * *

MOTOR BOATING.

The Blue Ensign.

The Motor Yacht Club has been granted the privilege by the Admiralty of flying the Blue Ensign of His Majesty's fleet on all registered vessels belonging to members of the club.

Naval Motor Boats.

At the suggestion of the A.C. de France, the French Minister of Marine is organising a competition for motor-driven boats suitable for use in the French Navy and general coast service. Such boats are to have engines of about 165 to 200-h.p., which must be either of the flash-steam type or oil engines using heavy oil, and must also be capable of starting from cold and developing half their full power within 10 minutes. Separate prizes are offered for the best engines (10,000, 8,000 and 6,000 francs), and for the best hulls (3,000, 2,000, and 1,000 francs), and the motor manufacturers have no choice in the matter as to which of the hulls (submitted by boat-builders) their engines shall be fitted into. Fuel power is to be developed by the engines at a speed of 500 to 600 r.p.m. The hulls are to be of wood, of between 17 and 20 metres in length, and a speed of at least 12 knots is to be maintained.

MOTOR CYCLING.

Land's End to John o' Groat's.

Interest is growing in this important trial, which the Auto-Cycle Club propose holding in the interests of the motor cycling industry during the coming season. It is thought that 300 miles per day for three consecutive days will prove too severe a strain for the drivers, and the suggestions which find favour are that the trial should extend over four or six days, with a day's rest in between the long distance rides. This would serve two purposes, by giving the riders a little breathing time, and enabling the competing machines to be on exhibition to the public at some important towns where the halt for the night would be made.

International Cup Race.

The course for this race, fixed to take place on June 29th, has been selected in South Bohemia. British support in enabling the Auto-Cycle Club to be adequately represented at the event is urgently needed. It is to be hoped that manufacturers, assisted by patriotic amateurs, will enter a goodly number of machines to compete for the honour of upholding British interests in the Eliminating Trials in the Isle of Man next May.

"Multi-Cylinder Engines for Motor Cycles."

Under the above title, Mr. B. Chatterton will read a paper before the members of the Auto-Cycle Club, probably next month. Mr. Chatterton, who is a member of the committee, has had considerable practical experience with a motor bicycle fitted with a 4-cylinder engine.

Quarterly Trials, January 20th.

For this 100 miles trial on the Oxford Road there are 19 entries.

PARLIAMENTARY CANDIDATES FAVOURABLE TO AUTOMOBILISM.

BELOW we publish a list, for which we have to thank the courtesy of our contemporary, *The Car*, of Parliamentary candidates at the present election who have frankly expressed views favourable to the progress of the automobile movement. Altogether some 400 intending M.P.'s are in favour of measures calculated to promote the benefit of the industry, and opposed to repressive or restrictive legislation. Of course we do not at present know how many of those whose names appear on our list will secure election, but in any case it is a favourable omen that so many are willing to adopt, and more or less distinctly pledge themselves, to favour the new locomotion. We certainly do not think that anything like 400 candidates would have been willing to do the same at the last election, and we may therefore hope that automobilism will receive fair, if not generous, treatment in the next House of Commons.

Our readers will, of course, understand that most of the candidates will have either been elected or put out ot the running by the time the present number of THE AUTOMOTOR JOURNAL is in their hands. The list will, however, prove valuable for future reference when automobile legislation is before the House of Commons.

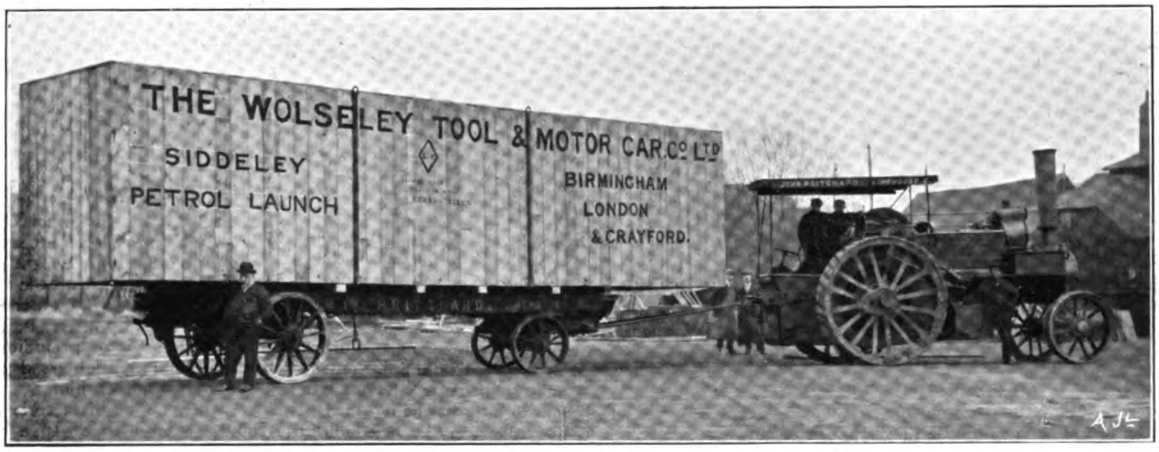
Wigtonshire—Lord Dalrymple.

⁂



Most of our readers who visited the Olympia Exhibition will no doubt remember the very fine 30-ft. motor cruiser which was exhibited at the Wolseley Company's stand in the Boat Section. Viewed under ordinary conditions, it is difficult to realise the imposing "presence" of craft of this class. The photograph which we give above of this boat, "crated" for shipment to Buenos Ayres, is therefore interesting as giving an idea of the size and importance of a boat of this character. The height can be well gauged from the men who are standing by.

Mr. Harvey du Cros, M.P.

ALL motorists will be glad of the return to Parliament of Mr. Harvey du Cros, whose interests are so closely bound up with, and who has been so prominent a force in the development of the automobile movement. In the new Member for Hastings we may confidently expect to find that the industry and pastime have secured a vigorous supporter in the coming Parliament.

CORRESPONDENCE.

⁂ The name and address of the writer (not necessarily for publication) MUST *in all cases accompany letters intended for insertion, or containing queries.*

THE FLYING PROBLEM.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Referring to the article in your last issue regarding aerial machines and the experiments of the Brothers Wright, it is known only to a few of the earliest pioneers of automobilism in this country that, in addition to having been the first to build an internal combustion engine motor car in this country and also the first to make a motor boat in this country, I have devoted much time and attention to the aerial machine problem.

In 1895, I made three experimental machines of small size, and based on these experiments, I took out a patent, No. 3,657, February 18th, 1896, with the intention of building a larger machine, propelled by a 4-cylinder petrol motor of 20-h.p., with the idea that this engine should be sufficiently powerful when fitted to the machine to lift the weight of one man. It was nearly two years later, however, in 1898, before I was able to commence the working drawings of the machine, owing to the demands on my time involved by the continuous changes and improvements in cars necessitated by the rapid growth of the new automobile industry. But when I had practically completed the working drawings for this machine, an entirely new principle of construction of these machines occurred to me, by which the effect of a bird's wings is obtained without any flapping action in the machine and without an aeroplane, or, to put it in another way, the reverse action of the parachute, that is to say, active instead of passive action.

There is no prior record of this principle, as far as I am aware—certainly not in Chanute, or any publication I have met with. I am convinced that it is on this principle that the aerial machine will come when it comes, as being so much more likely to be completely controllable and dirigible than the aeroplane.

I made a small model only a little over 2 feet in diameter, which was completely successful, in that it would rise to a greater height, and lift a greater weight, than the previous models having the same area. I sent the model up a number of times on Wimbledon Common, and later from the garden of my house on the river bank at Putney, with the tail and surfaces so set that I felt sure of its travelling in the desired direction. But on one occasion it encountered a wind current travelling lower than usual, and at quite 90° with the wind below. This took it down the river, into which it dropped, about 400 yards east of the iron bridge, and I was not able to recover it. I sent this up a considerable number of times on Wimbledon Common, and incidentally acquired a store of experience in connection with these small machines that rendered me quite confident of constructing successfully a machine propelled by a petrol motor to carry one man.

My first set of working drawings for a larger machine was, therefore, cancelled, and, owing to the pressure of other matters, I have been unable hitherto to proceed with a new set.

I am now about to commence the working drawings of the new motor-propelled machine fitted with a petrol motor of 28-h.p., and I shall be glad to send to THE AUTOMOTOR JOURNAL the results of further experiments when the machine is completed.

I shall also be pleased to communicate with anyone interested in the solution of this great problem.

Yours faithfully,
J. D. ROOTS.

Jan. 10th.

THE "GREAT UNPAID" AND THEIR LITTLE WAYS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—There has been considerable interest lately taken in the great discrepancy of the decisions given by the various Benches of magistrates in the country, and I think that the following great discrepancy of the judgment given by the now notorious Kingston Bench should be made public.

The last week in November, 1905, a police constable arrived at a gentleman's house in Surrey with a stereotyped notice that his car had been timed over a measured distance on the London Road, Esher, &c.

The constable was informed by the owner that he was not on his car on that day, and, unfortunately, in reply to the demand of the constable, gave the name and address of the gentleman who was driving his car.

The constable then journeyed to London and saw the driver of the car, and in his presence struck out the name and address of the owner of the car, and in pencil inserted the name and address of him, the driver. In due course a summons was issued, in which the name of the owner was struck out and that of the driver substituted in ink. The alleged offence was in the summons on "The Portsmouth Road, Esher."

I was instructed to defend, and the case duly came on on the 14th December. Superintendent Marks gave evidence that he was on duty on the Portsmouth Road, Esher, and timed car No. —, which passed him, and covered the measured distance at the rate, by his stop-watch, of 33 miles per hour.

The next witness was a sergeant who was on duty on the Portsmouth Road, also with Superintendent Marks, and he said he estimated the pace at 33 miles an hour, but had no stop-watch.

The superintendent and sergeant admitted that there was no danger to anybody, and no traffic on the road, that the car was not stopped at the end of the measured distance, and the sergeant could not in any way identify the car, and admitted that he would not swear whether it was a yellow, black, or any other colour car. This was the whole of the evidence as to pace.

I pointed out to the magistrates that under the Act the notice was incomplete, as it stated "the London Road, Esher" and that the only evidence and summons was of an offence on "the Portsmouth Road, Esher."

After consultation, the magistrates said they had decided to give leave to amend the summons, and this was done, altering the offence to "the London Road, Esher."

They offered to adjourn the hearing to permit of my bringing evidence as to speed, well knowing that it was absolutely impossible for any evidence to be obtained, and the case was consequently then decided.

The magistrates then intimated that they should fine my client £5 and 11*s.* 6*d.* costs. I objected to this, saying that no evidence whatever had been called that my client was on the "London Road, Esher," at all, but the chairman replied that everybody knew "the London Road" and "the Portsmouth Road" were one and the same. This I pointed out could not possibly be, as "the London Road, Esher," must be between Esher and London, and "the Portsmouth Road" between Esher and Portsmouth, and that it was absolutely unfair to decide that a notice and evidence given in this way was sufficient to comply with the Act. Notwithstanding this they convicted my client and inflicted the penalty.

I notice in the papers that the same Bench last week dismissed a case, because the notice only stated "Portsmouth Road, Cobham," on the grounds that it did not give the motorist sufficient indication of the exact position of the measured distance to enable him to prepare his defence.

That these two cases can be consistent, I think everyone will agree is utterly impossible. I explained to my client that in my opinion he would undoubtedly be successful on an appeal, but that, at the same time, costs of an appeal were scarcely ever allowed, and consequently although he would have conviction removed, he would have to pay about £30 to £40, and as this was his first offence (although he has been driving a car continually for four years) it was not worth while paying for such a luxury.

Yours obediently,
LEX.

Jan. 12th, 1906.

BRITISH *versus* FOREIGN CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—To your correspondent Mr. Sangster I would specially commend the reading of that old fable of Æsop, in reference to the serpent stinging its benefactor. Unfortunately Mr. Sangster is a politician, and to this alone I attribute his ungenerous attack upon foreign constructors, to whom he has always owed so much in the design and construction of his cars. Apart from politics, I am sure Mr. Sangster would admit this. He accuses me of prejudice, and in reply I would point out that I am particularly unbiassed in the matter, because I have a particular advantage over him by reason of my interests being in British as well as foreign factories, and, moreover, my knowledge of the subject extends back to a period years before Mr. Sangster ever dreamed of making motor cars.

No, sir. It may be to the advantage of British manufacturers like your correspondent that they should sell their cars without competition of *any* sort, but merit will always tell, no matter where the vehicle is made, and the public will buy it regardless of every other consideration.

Assuming your correspondent is accurate, and only five hundred foreign cars are sold in America, how is it that not 2 per cent. are British? Americans at the moment import motor cars, and why is it that France, Germany and Italy get the business?

Yours faithfully,
CHAS. JARROTT.

January 15th.

6 CYLINDERS v. 4 CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I do not think that Mr. Edge is serious in contending that a 6-cylinder engine does not take up more space than a 4-cylinder engine of the same horse-power.

Mr. Edge gives some figures which I venture to suggest are entirely misleading. It is not a question of distance from dashboard to front axle. I have already pointed out that the great disadvantage on the 6-cylinder engine is that the whole weight of the engine is placed far forward over the front wheels, causing wear on the front tyres, making the steering harder, and rendering the car less controllable. This can easily be appreciated upon inspection of a 6-cylinder car. In order to prevent the wheel base from being abnormal the bonnet is carried right forward until it projects at least a foot in front of the front axle, and this with the results I have mentioned is not only bad design, but is a very serious disability in my opinion.

As Mr. Edge has been good enough to give some figures, I shall be glad if he will oblige us with some more figures.

I have carefully taken the dimensions of a 40-h.p. Mercedes, belonging to a friend of mine, the design of which is absolutely up to date, and in which I notice the designers and constructors make a point of seeing the bonnet and engine do not project over the front axle in the slightest degree. This is, of course, as it should be, in order that the weight should be properly distributed.

The following are the dimensions which I took from the 40-h.p. Mercedes:—Length from dashboard to front axle, 2 ft. 9½ in.; from dashboard to front of front cylinder, 2 ft. 1½ in.; length from dashboard to radiator, 2 ft. 6½ in.

Will Mr. Edge kindly oblige with the corresponding dimensions of the 6-cylinder Napier?

Yours faithfully,
H. GLADSTONE COLEBROOK.

Guildown, Coolhurst Road, Crouch End.
January 15th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Mr. Hutton is so pleased with his little joke about "the twenty-ninth valve" that he has sent it to every motor journal, and one or two daily papers as well, so that no one might miss it.

When one recalls to mind the unfortunate attempt Mr. Hutton at one time made to build his own car, one is surprised that he should talk of complication when criticising the products of a successful manufacturing firm.

The arguments Mr. Hutton puts forward against the 6-cylinder car are precisely what he used against the 4-cylinder car when he was selling 5 and 7-h.p. Panhards.

He has since found the 4-cylinder car no more liable to break down than the 2-cylinder, and although it is true there are more working parts in a 6-cylinder engine than a 4-cylinder (not 50 per cent. more as Mr. Hutton says), you have "two more strings to your bow," and should a cylinder not be working, you could continue running with proportionately less inconvenience; but if Mr. Hutton will give himself experience with a high-class and properly-designed 6-cylinder car, he will find, as scores of private users have found, that the 6-cylinder car in practice is no more liable to breakdown than a 4-cylinder, and I am pleased to say we have found the same apply to the new 8 cylinder Rolls-Royce landaulets, which have surpassed our most sanguine expectations in this respect. These cars are practically indistinguishable, as regards silence and smoothness of running, from the best electric broughams, and this result can only be obtained by our 8-cylinder system.

It would be interesting to know what make of 6-cylinder car it is that has been giving Mr. Hutton such unsatisfactory results as compared with 4-cylinder cars.

Yours faithfully,
CHAS. S. ROLLS.

Jan. 15th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In common with, I suppose, most other people interested in automobiles, I have heard a great deal of late about the merits of 6-cylinder cars. Whether this arises from a genuine interest on the part of the motoring public or from other causes, I have, of course, no means of ascertaining, though personally I have seen no signs of the former cause, despite the fact that I meet many people who might be supposed to be in touch with public opinion on such matters.

Though I am interested in 4-cylinder cars, I have an open mind, and am prepared to become enthusiastic on 6-cylinders should results justify it. Therefore, I suggest that a proper trial be made between the two, and I am prepared to lend my assistance to such trial.

If one of the 6-cylinder advocates will make a match for a race—I beg pardon, "eliminating trial"—over say 100 miles of give-and-take country, against a 4-cylinder car of exactly equal engine capacity, I will be prepared to find the 4-cylinder car, and take up the cudgels. Then, if the 6-cylinder proves to be the better type, I shall be saved from future error, and my consolation will be that I shall have rendered some service to that large body of automobilists who are at present supposed to be in doubt and tribulation on this subject.

Yours faithfully,
Jan. 12, 1906. H. H. P. DEASY

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I am afraid that many of your correspondents are allowing themselves to be so far carried away by the fascination of the 6-cylinder car as to forget that there is a commercial side to the question.

My company was one of the first to manufacture successful 6-cylinder cars, which were exhibited at the Crystal Palace in February, 1904, and competed in the Glasgow to London run of that year. We found, however, that while the 6-cylinder car has many advantages, the cost of production must inevitably be very much higher than that of a 4-cylinder car of equal power, and as the soundest commercial policy is to court the class of buyer who will furnish the largest volume of trade for the longest period, we decided that to make the 4-cylinder car of ample power was better.

What may become in the future of the 6-cylinder world I do not know, but at present, judging from the prices prevailing, the 6-cylinder car cannot be considered suitable for even the moderately wealthy man.

The 4-cylinder car can be made as silent as any 6-cylinder (if I am wrong I shall be corrected, but I think I can demonstrate the truth of my statement), and power for power can be made practically as flexible.

It will, I think, be conceded that from 15 to 25-h.p. is powerful enough for this country, and that such a car is economical in up-keep. I should, therefore, be willing to match my 16-20-h.p. Sunbeam car against any 6-cylinder car of equal piston displacement per minute over a distance of say 1,000 miles, the points to be adjudicated upon being:—Silence, hill-climbing on top gear, flexibility on top gear in traffic, freedom from side slip, wear on tyres, and general reliability.

Yours faithfully,
FREDERIC EASTEMEAD.

Sunbeam Motor Car Company, Limited,
Wolverhampton, Jan. 10th.

* * *

A.A. Annual Dinner.

AT the Automobile Association's Annual Dinner, which, as already announced, will take place at the Trocadero Restaurant on Thursday, January 25th, the musical entertainment promises to be of unusual excellence. Several prominent members of *the* profession, including Mr. Arthur Roberts, are serving upon the Concert Committee, under the direction of Mr. Walter Gibbons, so well known in variety theatre circles.

The Theft of the Coupe de Pyrenees.

THE police have at last arrested someone in connection with the disappearance of the Coupe de Pyrenees Trophy from the Olympia Exhibition. They first of all took into custody a man named Hall on the charge of "frequenting the Exhibition for the purpose of committing a felony" (an indictment which suggests that the police have added to their recent accomplishments of ju jitsu and other up-to-date acquirements, the power of thought-reading), and to him they have now added another alleged delinquent, to wit, one of the name of Burn, who it is alleged, together with the man Hall of the felonious intentions, arranged with a Camden Town carman to convey a parcel from Olympia on the morning of November 25th. This parcel is presumed to have been the trophy, and the two persons have been remanded, in order, as the magistrate says, that they may be "brought up together."

THE MOTOR IN AGRICULTURE.—From time to time we have shown the Ivel agricultural motor working in various forms. A new instance is shown in the above picture, which was taken in a field near Biggleswade, Beds. In this the Ivel is hauling no less than three mowing machines, the cut of each machine being 6 feet, the three mowers therefore cutting 18 feet of grass at a time. The same work would take at least six horses to accomplish. In addition to the work being so much more rapidly carried out, it is claimed that the cost is half that of animal traction. The field operated upon was 8 acres in extent, and the whole was cut down in 2 hours, the consumption of paraffin during the work being 4 gallons.

Brussels Salon.

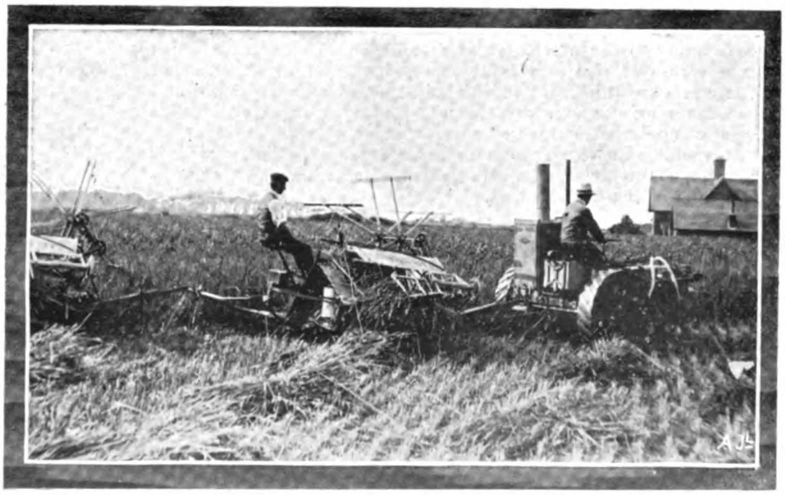
SATURDAY last was the opening day of this Exhibition at the Palais du Cinquantenaire, the 25th instant being appointed for the closing. Already the show has received strong patronage from the paying public, who are keenly interested in many of the fine chassis and car models which have already done duty at Olympia or Paris. With hardly an exception, all the leading Continental manufacturers are represented by their agents. British exhibits are not a feature of this Belgian annual fixture.

A Premium for Care.

THE excellent idea of giving bonuses to motor 'bus drivers for an absence of accident, has been adopted in the Ealing neighbourhood, and is said to have the effect of making the drivers extremely cautious and careful.

Follow the Light.

APROPOS of the proposal now being prominently brought forward to introduce a Bill to enforce compulsory lighting on all vehicles, the Guernsey authorities have just passed a measure compelling all vehicular traffic without distinction to carry a light at night. Hitherto only spring-hung vehicles were required to do so, but recently an accident occurred owing to the fact that a light van collided in the dark with an unlighted box-cart, one of the van's occupants being thrown out and fatally injured. The Guernsey authorities have not been slow to take the hint.



THE MOTOR IN AGRICULTURE.—Another picture of the Ivel motor hauling two reapers and binders and cutting a width of 10 feet at the same time. The work in this instance was carried out on Mr. Capon's farm of Hillside, near Biggleswade. The equivalent in animal power would have amounted to three horses to each binder.

4 and 6 Cylinders.

A LECTURE, illustrated by diagrams, upon this subject, was announced to be given by Mr. Donald G. Snodgrass, B.Eng., to the Automobile Class at the Northampton Institute, Clerkenwell, on Thursday of this week.

Tramways or Motor Omnibuses.

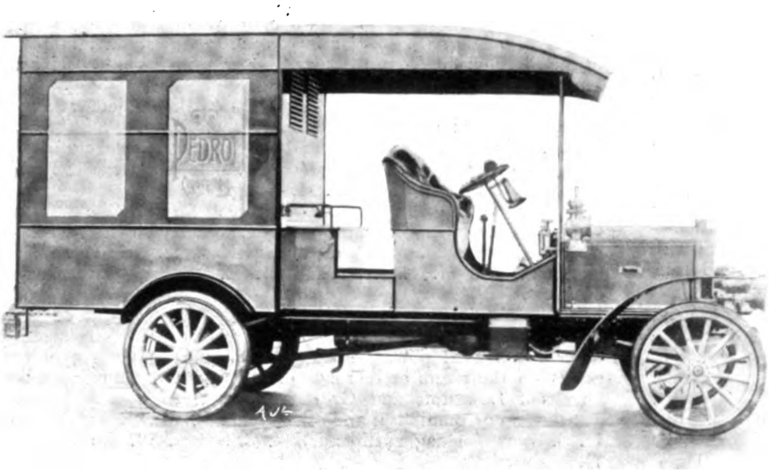
OXFORD ratepayers are up in arms at the proposal of the Town Council to electric-tramify the town at a cost of £180,000. At a recent meeting of the ratepayers, by an overwhelming majority, resolutions were passed in favour of a service of motor omnibuses instead. The question appears likely to result in a poll to arrive at a satisfactory solution.

"Omnia."

A NEW well-illustrated automobile weekly publication, under the above title, edited by M. Baudry de Saunier, at 20, Rue Duret, Paris, has made its appearance with the new year. The newcomer is to deal with all branches of the sport and industry, and the name of its editor is, needless to say, a guarantee of its general excellence.

Second Annual Birmingham Motor Car Show.

THIS Show, at Bingley Hall, opened at 3 p.m. on January 19th by the Right Hon. the Lord Mayor of Birmingham, will remain open until January 27th. The exhibits, which are more numerous than at the first Show, include models of leading British and Foreign manufacturers. The band of H.M.'s 1st Life Guards has been engaged to perform daily. Five per cent. of the gate receipts will be given to local charities, in like manner to last year.



A 24-h.p. Thornycroft Chassis fitted with a special body suited to the commercial requirements of the British American Tobacco Company. The van is intended for work in India, and behind the front bucket seats a second row is provided to seat coolies. Special attention has been given in its construction to the question of ventilation. The vehicle is now on its way to Bombay.

COMMERCIAL POINTS.

To Ring Up Argylls, London.

MESSRS. ARGYLLS, LONDON, LIMITED, advise us that in consequence of the delay occasioned their clients through the want of proper telephone connections, they have now two lines to their Newman Street premises. The new numbers are 2,641 and 2,642. Last week the builders commenced the demolishing of the old property leading to Rathbone Place, and in the course of two months or so, the commodious premises in Newman Street will be doubled, and accommodation for over 400 cars arranged for.

The Humber Works' Dispute Settled.

A SETTLEMENT of the dispute at the works of Humber, Limited, Beeston, has been satisfactorily settled, and work is now in full progress. About 90 society men recently handed in their notices, and left work on account of alleged preferential treatment, but the matters in dispute have now been cleared up. We understand that owing to the removal of certain society restrictions that were in force in the past, the output at the works is now considerably increased, while the men are actually earning more money.

New Cars for Old.

THE offer made a little time ago by the Gladiator Company to exchange an old car for a new 1906 Gladiator model, under certain conditions, expires, we are reminded, on the 31st of the present month.

MESSRS. R. AND J. PULLMANN received last week an order from the British Automobile Commercial Syndicate, Ltd., to re-tread two of the Pullmann non-skid covers. Accompanying the instructions, a gratifying testimonial was included in a letter, as follows:—"We are sending you two of your non-skid covers to-day, which have been running successfully now some 6,000 miles. These non-skids were supplied to the car (which is a 22-h.p. Spyker) in June last, and have been used by the owner for 3,000 miles. We have used the car for demonstrative purposes, and running about London for 2,000 miles. This mileage has been accounted for by a Smith's Speedometer."

MR. SIDNEY GIRLING, who was at the wheel of the Siddeley racer in the last Eliminating Trials for the Gordon Bennett Cup, ru in the Isle of Man, has, we learn, joined the staff of A. Darracq and Co., Ltd. Mr. Girling will be in attendance on the stands of the Darracq Company's agents at all important shows throughout the country, and will have for demonstrating purposes one of the Company's latest productions—the 20-32-h.p. Darracq.

MR. ERNEST H. ARNOTT, who had the management of the Minerva Car Department at Messrs. C. S. Rolls and Co., until they discontinued the agency, advises us that he has secured the sole selling rights in the United Kingdom for a new model Minerva car, which is to be produced for the 1907 season. He will begin to receive deliveries about September of this year. The new model is being built to Mr. Arnott's specified requirements. Although Mr. Arnott's agreement does not terminate with Messrs. C. S. Rolls and Co. until late in the year, they have consented to accept his resignation in order that he may keep unbroken his interest in and connection with Minerva cars. Negotiations are in progress for premises in the West End, and in the meantime communications should be addressed to Mr. Arnott, at Bolton Lodge, Teddington-on-Thames.

THE EARL OF ABERDEEN, the new Viceroy of Ireland, and His Grace the Duke of Sutherland have both just recently commissioned the Daimler Company to build them high-powered cars, each to have a 10 ft. wheel base chassis.

MR. GORDON USMAR, who has hitherto been associated with the Anglo-American Oil Company, has now joined Messrs. T. H. Harman and Company, Limited, of Regent Street, as a managing director. In his new capacity, Mr. Usmar will be connected with the sale of Vinot cars, for which his firm has the sole agency in this country. In his private capacity, however, he is already familiar with this make of vehicle, for both he and his car have for long been a popular figure at automobile meetings throughout the country.

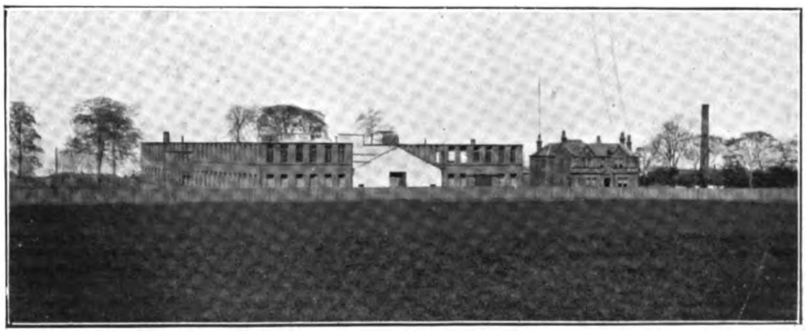
THE F. W. Peckham Motor Syndicate, Ltd., have sent us their advance Show catalogue of the Maxwell cars, which they are handling for this country. Full specifications appear in this. The syndicate at the same time inform us that they have adopted the instalment plan in introducing the Maxwell 2-cylinder 8-h.p. car, but without any addition to the listed price. Under their scheme the hire-purchase system is entirely eliminated, and the sale is made outright, the purchaser becoming the actual owner of the car upon receiving delivery.

AT the Birmingham Show the latest Clement car models will be exhibited at Stand No. 60, by Messrs. Neweys, of Birmingham.

WEST, LIMITED, manufacturers of the West Motor Cars, have appointed Mr. Robert Wight, Junior, of East Newington Place, Edinburgh, agent for Scotland for the "West" cars.

PRICE'S PATENT CANDLE COMPANY, LIMITED, advise us that they are making their motor specialities in oils, greases, clutch dressings, &c., a prominent feature at the many motor shows during the next three months, including those at Brighton, Birmingham, Crystal Palace, Edinburgh, Manchester, Glasgow, and Agricultural Hall.

MESSRS. HUMBER, LIMITED, have now on view at their show rooms, 32, Holborn Viaduct, Holborn Circus, E.C., a 4-cylinder 8-10-h.p. landaulette, which has been specially constructed for use in the London district. This car has been built with a short frame and special body for use in London, or wherever there is heavy traffic.



A view of the works of the Scottish United Engineering Company's works at Granton, Edinburgh, from which it is announced, a number of home-built cars will shortly issue.

NEW COMPANIES REGISTERED.

Bromley and District Motor 'Bus Company (Limited), 4 and 5, Sundridge Road, Bromley, Kent.—Capital, £5,000 in £1 shares. E. W. Sawyer, permanent managing director.

William E. Cary (Limited), 37, Adeline Street, Red Bank, Manchester.—Capital, £60,000 in £10 shares. Object, to acquire the business of a coach spring and axle manufacturer, &c., at Manchester and Birmingham. First directors, W. E. Cary, C. E. Cary.

Highways Transit (Limited), 59, City Road, E.C.—Capital, £100 in 1*s.* shares. Object, to adopt an agreement with Ed. Surcouf et Compagnie and Robert W. Blackwell and Co., Limited. First directors, R. W. Blackwell and E. Surcouf.

Metropolitan Fare Register Company (Limited), 3, East India Avenue, Leadenhall Street, E.C.—Capital £100,000, in £1 shares (20,000 founders'). Objects, to carry on the business of manufacturers of and dealers in taxameters, &c. First directors: L. Weiller, R. Millet, C. Mascart, F. Espir, and W. L. Matthews.

George Riddell and Co. (Limited), Falconer Street, Newcastle-on-Tyne.—Capital, £1,000 in £1 shares. Object, to acquire the business carried on at Falconer Street, Newcastle-on-Tyne, as George Riddel, motor van and trolley builders, engineers, &c.

Simplex Pneumatic Rotary Starter Company (Limited), 26, Birley Street, Blackpool.—Capital, £1,200 in £1 shares (600 deferred). Object, to acquire patents, &c., in respect of the Simplex Pneumatic Rotary Starter (provisional specification No 13,234 of 1905).

Slatter, Eastgate, and Co. (Limited).—Object, to acquire the businesses of coach builders carried on by J. T. Slatter and W. H. Eastgate respectively, and to carry on the same and the business of automobile and general vehicle builders, &c. First directors, J. T. Slatter and W. H. Eastgate.

H. E. Steel (Limited), 27, Regent Street, Cheltenham.—Capital, £10,000 in £1 shares. Object, to carry on the business of electrical, automobile, and general engineers, &c. H. Ripley, first chairman, and H. E. Steel and H. E. Ripley, first managing directors.

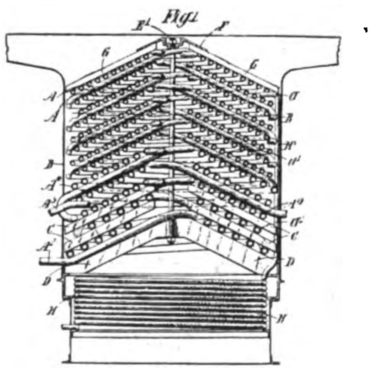
Sterry's River Trips (Limited).—Capital, £5,000 in £5 shares. Object, to build and work vessels propelled by steam or other mechanical power, for the conveyance of passengers and goods on the rivers and broads of Norfolk and Suffolk and the havens of Lowestoft and Great Yarmouth, to own and turn to account motor omnibuses and other vehicles, &c. First directors, H. S. Sterry (managing director), R. C. Sterry, W. Robbens, and H. Wainwright.

Traction Unification (Limited).—Capital, £10,000 in 1*s.* shares. Object, to undertake any business relating to the application of natural, animal, or mechanical power, or totraction, haulage, conveyance, or other similar operations.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

5347. 14th March, 1905. Improvements in or relating to Steam Generators. Thomas Clarkson, Moulsham Works, Chelmsford. This invention has for its object to construct a steam generator of the flash type, more particularly suitable for use on motor vehicles. There are two figures. Fig. 1 is a sectional elevation. The generator comprises a series of similar conical coils, A, having the apices or smaller parts of the coils directed upward. The water enters the coils at *a*, at the lowest convolution of the uppermost coil, and after circulating through this coil passes from the apex thereof downwardly by a pipe, A^1, to the lower convolution of the second coil, and after passing through this coil is led from the top thereof by a similar pipe, A^1, to the lower convolution of the third coil and so on until it reaches the lowermost convolution of the lower coil. The coils are all similarly connected, as shown, and the generator may be constructed of a single length of tubing. The diameter is increased towards the lower part of the generator, as shown at a^1, and still further down at the hottest part the thickness of the metal is also increased as shown at a^2. The coils being so arranged, and the fluid always entering at the lower part of a coil, and passing therefrom at the upper part by a tube which extends downward to the lower convolution of the next coil, the coils each serve in themselves to trap steam, and prevent it rising to the water inlet end of the generator, the result being obtained without the employment of any extra steam-trapping device. The pipes, A^1, serve also as distance pieces between the adjacent coils, and these pipes are arranged or staggered, so that one pipe, A^1, is approximately diametrically opposite to the next pipe, A^1. Between the coils and at the side opposite to that along which the pipes, A, extend, distance pieces, C, are introduced, the remaining distance pieces being omitted from the drawing for the sake of clearness. B is the surrounding casing. The water can be led to the upper end of the generator preferably by a heating coil, H, arranged in the lower part, and from this coil, H, it passes by a pipe, H^1, to the upper coil, A. The parts are kept in position by a four-armed support, D, and by plates, G, resting on the upper coil. These parts are bound together by a bolt, E^1, which extends through the support, D, and a cap, F. The steam is led to the regulator from the pipe, A^2, at the lowest end of the generator, and after passing through the regulator enters the generator proper by the pipe, A^3, whence it passes through the coil, A, and is led from the upper end of this coil to the throttle by the pipe, A^4. The coil, A, serves as a superheating coil.—December 27th, 1905.



28276. 23rd December, 1904. Improvements in Carburettors for Internal Combustion Engines. Charles H. Bryant, 12, the Embankment, Twickenham, and Arthur Watling, 9, Southampton Street, High Holborn, London, W.C. Although called a carburettor this is really a vaporiser, as it is not intended to be used with petrol or spirit. There are two figures. Fig. 1 is a sectional elevation of the apparatus. A single casing, *a*, is formed with a tube or tubes, *b*, so that the exhaust gases from the cylinder or cylinders of a motor may pass through and beneath the casing, *a*, before issuing to the atmosphere by a pipe, *c*, when the tube or tubes, *b*, is or are arranged for connection with a two-cylinder motor. Projecting from the base of the casing, *a*, is formed a convolute web, *d*, which upon the bolting of a suitable cover, *e*, to such casing, *a*, forms a spiral passage, *h*, leading from the central portion to the outer portion of the casing, *a*. The casing, *a*, has inlet and outlet openings, *i* and *j* respectively, the latter for connection with the combustion chamber of the motor and the former for the reception of the one end of a tube, *k*, having a delivery nozzle, *l*, the other end of which tube, *k*, communicates with a valve chamber, *m*. The passage, *n*, in tube, *k*, is formed with a series of restrictions of its bore, and communication with the valve chamber, *m*, is made by way of a stepped cone-shaped opening, *o*, which connects the passage with a glass casing, *p*. Fixed to the tube, *k*, is a second tube, *q*, which is formed into a plug and tapered externally at its lower end, and connected at its upper end with an oil supply tube, *r*, having a boss, *s*, and an extension, *t*, provided with a screw-valve, *u*. Upon the boss, *s*, is fixed an air supply tube, *v*, having a cap, *w*, fitted. The air admitted through tube, *v* is conducted by passages, *x*, formed in the boss, *s*, into the casing, *p*, surrounding the tube, *q*. In the passage of tube, *q*, is placed an oil supply valve, *y*, connected by pins, *z*, passing through slots, 1, in the tube to a sleeve, 2, mounted on the tube, *q*. The sleeve is provided with a circular diaphragm, 3, and a number of openings or slots, 4, adapted when the valve, *y*, is opened to allow a supply of oil to issue from openings, 5, formed in the vertical tube, *q*. The oil supply valve, *y*, is normally retained against its valve-seating, 6, by a spiral spring, 7, which bears against the diaphragm, 3, and at the other end against a collar, 8, formed on the tube, *q*. The closed end of the passage, 9, of the tube, *q*, has one or more holes, 10, to permit escape of air and any collection of oil. A pipe, 11, conveys the oil fed from the oil tank to tube, *r*, and passage, 9, of the tube, *q*. The suction created by the piston of the motor draws air through the air tube, *v*, and air passage, *x*, to the valve chamber, *m*, and causes a downward movement of the diaphragm, 3, and sleeve, 2. The valve, *y*, is opened, and a charge of oil supplied through the openings, 5, of the tube, *q*, and slots or openings, 4, of the sleeve, 2, into the valve chamber, *m*. The diaphragm, 3, being of less diameter than the casing, *p*, the air passes beneath the diaphragm. The charge of oil, together with the air, is drawn into the tube, *k*, and by the delivery nozzle, 1, is sprayed into the central portion of the casing, *a*, from whence it flows round the spiral passage, *h*, to be finally drawn into the cylinder, there to be mixed with a main supply of air to form an explosive mixture.—December 27th, 1905.

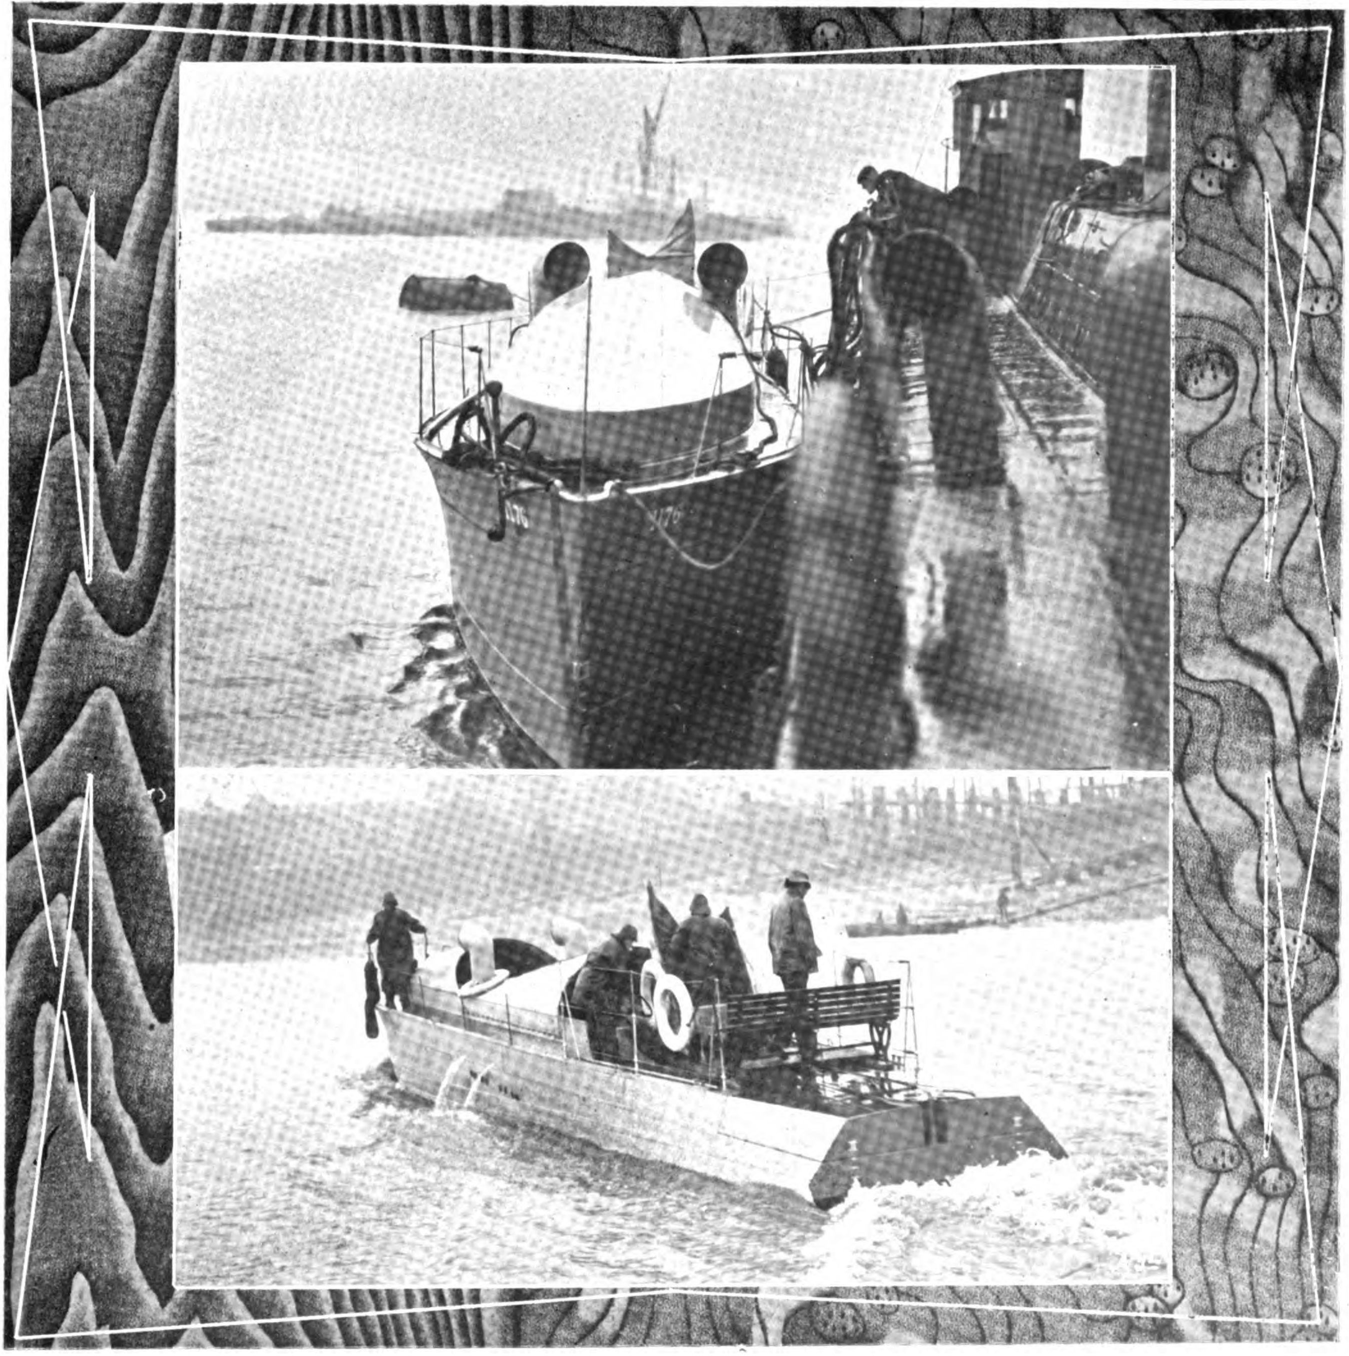
The AUTO MOTOR JOURNAL

(YELLOW COVER).

A Record and Review of Applied Automatic Locomotion.

No. 64 (No 4. Vol. XI.)] JANUARY 27TH, 1906. [Registered at the G.P.O. as a Newspaper.] Weekly, Price 3d. Post Free, 3½d



THE YARROW-NAPIER MOTOR TORPEDO BOAT.—Among the latest boats launched by the famous shipbuilding firm on the Isle of Dogs is a second-class motor torpedo boat, No. "1176." Her three engines have an aggregate of about 300-h.p., and in all there are twenty cylinders. Two coupled, 4-cylinder Yarrow-Napier marine engines drive each port and starboard propeller and a single, central, 4-cylinder engine is used for starting, manoeuvring, and going astern. As shown in these photographs, the boat is only in trial condition, but when fully equipped she would have a pivoted torpedo tube on the forward deck and a small quick-firing gun aft (see our article, page 103).

PASSING EVENTS.

A Tourist Trophy Resumé.

On another page we this week reproduce a paper, read by the technical editor of this journal before the Automobile Club, on the various aspects of the Tourist Trophy Race, which is to be held again this summer. Under ordinary circumstances we might perhaps be expected to reproduce the paper without comment. But the circumstances are *not* quite ordinary. Since the first proposals to hold a competition of this description were put forward, or at any rate since the moment when they began to assume practical shape, The Automotor Journal has been working in full sympathy with the Technical and Races Committees of the Automobile Club, for the purpose of rendering the rules governing the competition as suitable and comprehensive as possible, and the event itself as successful as could be. Our readers will remember the large amount of space we have devoted to the question, and the large number of tables and calculations we have prepared and published for the purpose of throwing light on various aspects of the competition. In spite of all that we have written, however, and in spite of the amount of attention that has been devoted to it by the two club committees referred to above, we are still aware that the principles involved in the Race that was actually run in the Isle of Man and will probably be held again and again—during subsequent years—in a more and more improved form, are still very largely a matter of mystery to the great bulk of automobilists. To put the matter shortly, there are still a good many people of intelligence who are interested in automobilism who cannot eliminate from their minds the idea that the main object of the Tourist Trophy is to test the fuel consumption of the ordinary makes of car. The opportunity provided by the club to the technical editor, of putting before the bulk of the club's members, and in consequence automobilists generally, the objects for which the Technical and Races Committees have been striving, was, in consequence, one not to be neglected, both with the view of rendering the problem more widely understood—of, in a certain sense, popularising the Tourist Trophy question—and at the same time of enabling automobilists generally to form an opinion upon the conclusions to which the Races and Technical Committees had come, and to realise the immense amount of work that had been involved. It is because the paper which we reproduce is specially designed for this purpose, and because comprehension of the situation by automobilists generally is so important with a view to future developments, that we not only reproduce the paper in full, but comment on it in this part of the journal.

◆ ◆ ◆

Satisfactory Recognition.

It is pleasing to find that in the discussion which followed the reading of the paper, recognition was accorded to the amount of work done by the staff of The Automotor Journal in connection with the Tourist Trophy Race, and to note that members of the club who have taken a leading part in the elaboration of the rules and the organisation and management of the race have accorded a full meed of recognition to the extent to which The Automotor Journal has been a contributor to the development and success of this important competition. This recognition is the more satisfactory to us, inasmuch as we believe we are correct in stating that The Automotor Journal is the only automobile publication which has done anything at all to place the various aspects of the Tourist Trophy problem intelligently before the public, and that in as far as automobilists generally—excepting, of course, those who have been in special touch with the preliminary discussions and arrangements at the club—adequately comprehend the situation, their comprehension is in a large measure due to the amount of time, trouble, and space which we have devoted to the subject.

◆ ◆ ◆

A Principle to be Encouraged.

Apropos of the discussion on the Tourist Trophy referred to above, the very well-considered remarks of Mr. Coleman, who took a leading part in it, raised a side issue of much general interest, and suggested a principle which it would be satisfactory from every point of view to see regarded either as one of the unwritten laws of the Automobile Club, or, better still, embodied in something of the nature of a "standing order." We refer to Mr. Coleman's suggestion that the committee of the club, in deciding all events of a competitive character, should be governed entirely by a "sporting spirit"—that is to say, that any member of the committee who may have a definite financial interest in any particular type of car which might be concerned by, and affected either beneficially or adversely by, a measure proposed, should refrain from exercising his vote on the committee. He should, of course, be permitted to discuss it fully, to express his opinion from every point of view, and do all he can to show the club in what way the interests of those concerned are likely to be affected. But there his concern with the matter should end, and when the question is put to the vote it should be decided by the votes of those who will look at it without any suggestion of interest affecting the manner in which they determine it. The proposal, as we observe, is one which, in the interests of any movement, has much to recommend it. We do not for a moment desire to cast the slightest reflection on past decisions of the Club Committees in such matters. But the great body of manufacturers and those pecuniarily interested in the trade would certainly feel satisfaction if they knew that the ultimate decision of all such questions were left in the hands of men who look at them from a disinterested point of view, and there is no doubt whatever but that motorists in general cordially welcome an authoritative recognition of this principle.

◆ ◆ ◆

A Further Triumph for the Petrol Engine.

More than once have we had occasion to remark that the success of the petrol engine as applied to boat propulsion has as yet been far less conspicuous and not nearly so fully developed, generally speaking, as its employment as the prime mover of cars and other vehicles. Possibly this is due, amongst a variety of other causes, to the motor-propelled boat making a less direct, or at any rate a less general appeal, to the utilitarianism of the community at large. Ever since the fine performances of the Napier boats, however, and the good service they have rendered in connection with military and naval manœuvres, we have insisted upon the importance which the petrol-driven boat must ultimately assume for the purpose of naval defence. It is therefore with great satisfaction that we draw the attention of our readers to the illustrated account, which we give on another page, of the petrol-driven torpedo boat, provided with Napier-Yarrow engines, which has been built by Messrs. Yarrow, and subjected to a course of successful trials recently on the Thames. The boat has been built throughout, engines and all, by Messrs. Yarrow, the engines, however, being made according to designs and drawings furnished by Mr. Napier. The occasion provides the first appearance of the petrol-engined boat of this type, and that is the first point of interest in regard to the trials to which we refer. The second is the very fine performance of the finished boat. It is only, as our readers will see from the account which we publish, sixty feet in length, and belongs therefore to the class known in the Navy as second-class torpedo boats. It has developed, however, the fine speed of 26¼ knots per hour—a speed which has hitherto only been accomplished by first-class torpedo boats, which are of considerably larger dimensions, and have considerably greater engine power. Among other advantageous features of the new boat must be mentioned the small amount of "bow" wave which it throws up in front of it, owing to its great buoyancy, as compared with a steam-propelled torpedo boat—a characteristic which, of course, has also assisted it in attaining its high speed. The absence of bow wave, and the small size and compactness of the little vessel, render it considerably less conspicuous than any of the ordinary types of torpedo boat at present in use. This, needless to say, is one of the greatest advantages which a torpedo boat can possess, as it is on its comparative invisibility that it depends for its immunity from annihilation. That the new boat should combine so many advantageous characteristics may indeed be regarded as a triumph for the application of the petrol engine to this particular purpose, and may lead us to hope that in the near future it may, at any rate for torpedo boat and possibly for scouting work, prove to be of the greatest service to the country.

◆ ◆ ◆

The French Grand Prix. One really does not know what to say about the French Grand Prix, except that it is now quite certain that it is going to take place, though how far the rules will modify the character of the event from what its original promoters contemplated is a question on which we must reserve judgment till the regulations which govern it have been settled. There is no doubt that it will prove a great, attractive, and exciting spectacle and, recognising this, we have throughout recorded minutely all news in regard to it as soon as they have been available. We have, as is our custom, kept in close touch with the arrangements of the French Club in the matter, and have generally provided all the information necessary to keep our readers fully conversant with the progress being made in its gradual materialisation. As a matter of fact, we were the first English journal to point out what the precise course would be, to indicate that it would very likely extend over two consecutive days, and to announce the important regulations that have been made in regard to tyre manipulation during the race. Last week we published a sketch map of the selected course—perhaps it would be more correct to say the battle-ground—and this week we are publishing a more detailed map, together with a number of photographs of the more interesting points of the course. No doubt, as we have already said, it will be a tremendous affair. There will be great enthusiasm, particularly among French automobilists, who will come from all corners of the Republic in vast numbers to witness it. The course is straight, and, in general, level, with no difficult corners, and the speeds registered, we may be quite confident, will be terrific, for it will not be like the Gordon-Bennett Race in the Auvergne, where the modern racing monster was prevented by an intricate and difficult course from developing its full whirlwind speed. What it will show, and what it will teach, either to the public or to engineers, is, however, another matter altogether. Frankly we do not anticipate that anything new or useful will be learned. Mere speed racing, without restrictions for eliminating pure "speed-machines," seems to us, and we believe to the vast majority of automobilists, to have had its day of usefulness. It has undoubtedly done good service in the past, but we should not have been over-grieved had the last Gordon-Bennett been the last race of the kind, and we believe manufacturers generally would have been glad also.

A Case Beyond Comment. Last July, Mr. F. W. Perkins was driving a motor car belonging to Mr. W. Dunn, of Lillystone Hall, Stock, Essex, up a hill near Margaretting. On this hill an accident occurred, in which a little girl collided with the car and broke her arm. The driver of the motor car was arraigned before the Chelmsford magistrates on the usual charge, and at the adjourned hearing Mr. Staplee Firth, who represented the defendant, informs us that he actually observed on the Clerk's table the conviction form already filled in, the Clerk having obviously concluded that, as it was a motor car case, conviction was a foregone conclusion. A very *ex parte* account of the occurrence had already appeared in the *Essex Weekly News*, in which Mr. G. W. Taylor, one of the magistrates who sat on the Bench and tried the case, is financially interested.

Under the circumstances the case was brought into the Divisional Court on Tuesday, and a *rule nisi* applied for; i.e., a *rule* to call upon the magistrates to show cause why the conviction should not be quashed on the ground of gross prejudice, &c., &c. The Divisional Court on the facts being cited at once granted the order. The case must accordingly be regarded as at present *sub judice*. What further remarks might be made on the subject must therefore be reserved till the matter has been finally settled. In the meantime we may point out that a previous conviction against Mr. Hassall by the same Bench was recently quashed by the Divisional Court, and may also mention that the hearing of an actual case usually follows a few weeks after a "rule" has been made.

⁂ ⁂ ⁂ ⁂

The Forgiveness of Queen Margherita.

THE foolish youths who attempted to endanger the life of the Dowager Queen of Italy, by erecting a barricade of stones on the road her automobile was expected to travel, were, as we have chronicled, committed to prison for their dastardly and senseless outrage. The Queen, however, with her proverbial kindliness, has obtained their release, and a short time back visited them in prison, and personally presented them with their pardons. We hope this will not have the effect of encouraging other hooligans to do likewise.

GRAND PRIX DE L'A.C. DE FRANCE

MAP OF THE SARTHE CIRCUIT

THE SARTHE CIRCUIT—the Course for the A.C. de France Grand Prix Race. The straight stretch of road between Connerre and La Fourche le Mans, one of the proposed spots where the start and finish is to take place. (1 on sketch map).

THE SARTHE CIRCUIT—the Course for the A.C. de France Grand Prix Race. A forked road at Yvry. (2 on map).

We were enabled last week not only to announce the selection by the Sporting Commission of the A.C. de France of the Sarthe Circuit for the big speed event of the A.C. de France this year, but we were also able to publish a confirmation of our previous statements that the race would possibly extend over two days, and that the manipulation, repairing, and changing of tyres would have to be entirely undertaken by the driver and mechanician of each respective car. These important departures on the part of the French Club are, unquestionably, steps in the right direction, and will tend to render the race somewhat more of a sporting event than this type of contest, with its armies of assistants, has hitherto been on the Continent. The feeling of the Sporting Commission was so pronounced in regard to the race being held over two days, only three votes being given against it, as stated by us last week, that the Committee of the A.C. de France had no hesitancy in accepting the recommendation of the Commission after the "opposition" had been afforded an opportunity of placing their views before the Committee. The broad principles of this important speed meeting have therefore now been definitely agreed to, and it only remains for the detailed regulations to be promulgated, based upon the principles laid down.

The chief points which remain in abeyance are those of the actual date for the race, in June or July, and the entrance fee per vehicle. Although officially the actual name of the event has not been announced by the French Club, there is little reason to doubt that it will

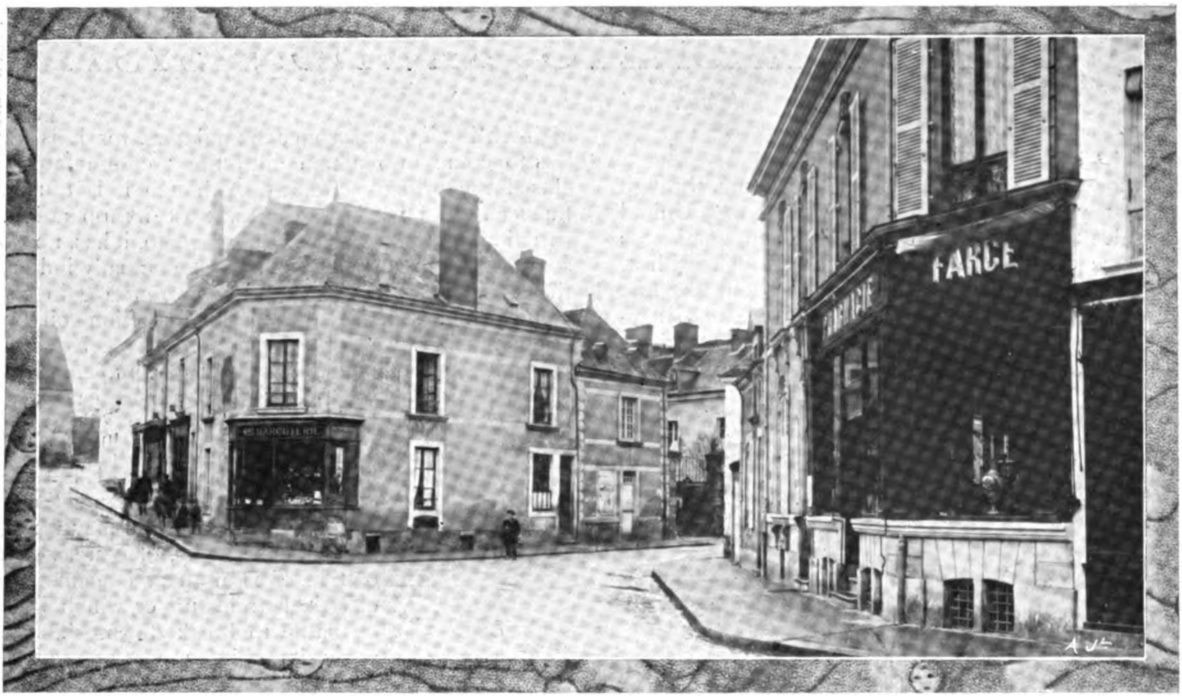
be, as hitherto, known by the title of the Grand Prix de l'Automobile Club de France.

Regarding the Sarthe Circuit, and its suitability for the race, as we stated last week, the extraordinary straightness of the majority of the roads forming the course selected will permit of the very highest speeds being maintained over very considerable distances, and reduce the event to a speed race pure and simple. In only a few cases would the road have to be "amended" to enable the cars to have still further opportunities to maintain their speed, these points being at Vibraye, St. Calais, Ardenay and La Fourche le Mans. In the latter case it is hoped that arrangements could be made for a good round sweep to be constructed through the Auvours Camp, which is situated in the angle formed by the forked roads leading from Mans to Ferté Bernard and St. Calais respectively.

At Vibraye, in addition, a detour is suggested through the Vibraye Forest. The distance over the whole course may roughly be taken at 104 kiloms.

The most suitable point for the start is considered to be on the straight stretch near St. Mars (4 kiloms. from Connerre and under 1 kilom. from Pont-de-Gennes railway station) shown in one of our photographs (No. 1), and indicated by a number, as also are the other views which we give of the course, on the detailed sketch map which we publish this week. The "straight" in the course comprises not less than 80 kiloms. of the whole, and might almost be said to approach nearer 90 kiloms. The roads are, generally speaking, in splendid condition, and there will be no difficulty, at a comparatively slight cost, in remedying any defects of the surface which at present may exist. As stated last week, there is only one level crossing, viz., at St. Calais (see photo No. 4), and it is hoped for the race days to arrange that a minimum of railway traffic shall pass over this point. At Vibraye the railway goes under the road, and at Connerre the railway crosses by a bridge. In regard to the course being served by railways, no better selection could be made, as the Paris-Brest line runs parallel with the whole length of the

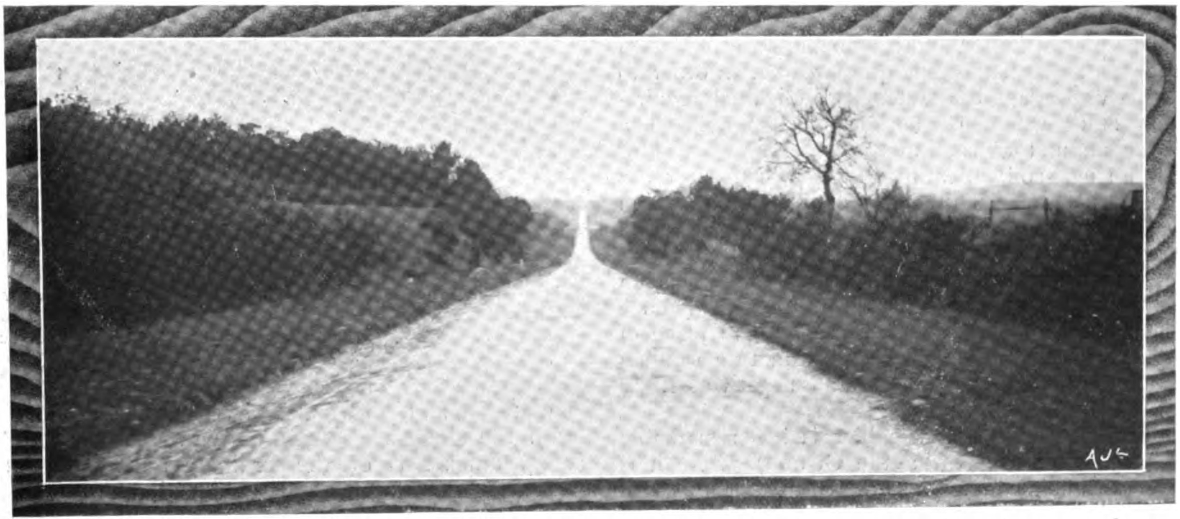
THE SARTHE CIRCUIT—the Course for the A.C. de France Grand Prix Race. The approach to Connerre Village. The course turns off sharply at the church seen in the distance. (8 on map).



THE SARTHE CIRCUIT—the Course for the A.C. de France Grand Prix Race. Sharp turn in the village of Connerre. (9 on map).

starting side of the course, from Le Mans to Ferté Bernard, with six stations within this distance. On the south side of the course, two stations, viz., at Bouloire and St. Calais serve, and on the east side Vibraye Station is situated exactly in the middle of that side of the course. In addition, visitors will, without difficulty, be enabled to get easily by rail from each side of the inside of the triangle to the other sides, as the lines crossing from different directions join the Paris-Brest line at Connerre. Intercirculation between points will also be specially easy, owing to the number of excellent urban roads which exist in every direction, and arrangements are to be made for bridging over at several points of the course to enable traffic to continue uninterruptedly during the racing. The station at Pont-de-Gennes, the suggested starting point, is within three hours of Paris and twenty minutes of Mans, whilst the ordinary fare from Paris is eight francs only, both very important factors likely to help enormously towards a huge crowd assembling. The actual distance to Le Mans from Paris is 209 kiloms.

Excellent telephonic and telegraphic installations are already at a number of the points on the course, and the local authorities, needless to say, are all enthusiastic in their desire to support the event locally, and to organise fêtes, &c., for the occasion. Le Mans is, moreover, a town of considerable importance, having about 70,000 inhabitants, and has historical automobile claims from the fact that it is the home and place of business of some of the earliest workers in the automobile industry, such as MM. Leon and Amédee Bollée, and such well-known champions in the automobile world as Henri and Achille Fournier, Hemery, Paul Jamin, &c. Finally, in addition to excellent hotel and other accommodation at Le Mans, both at St. Calais and Ferté Bernard considerable facilities will be found in the same direction.



THE SARTHE CIRCUIT—the Course for the A.C. de France Grand Prix Race. One of the long straight runs on the circuit. This road is between St. Mars and Connerre. (10 on map).

HIGH-TENSION MAGNETO IGNITION SYSTEMS.

(*Continued from page* 11.)

THE "CASTLE" SYSTEM.

So well-known has the name "Castle" become, through the popularity of the goods supplied by the United Motor Industries, that it is in itself sufficient guarantee of excellence among motorists who are familiar with it. When the Castle high-tension magneto system was first introduced, the magneto proper was of the real high-tension type, and contained within itself everything except the distributor. Since then, however, the system has been altered, and a low-tension magneto is now employed in conjunction with an external induction coil. Unlike most such systems, the induction coil is in this case of the "trembler" type, which consequently dispenses with any form of positive "contact-*breaker*," such as is usually fitted to the magneto itself. At the same time, an ordinary "commutator," or contact-maker, is nevertheless employed, but this also is an independent unit. So far as the magneto is concerned, therefore, absolute simplicity is the ruling factor. As a unit, it is a low-tension magneto pure and simple, and it carries no supplementary mechanism of any description. Some motorists still prefer to use a multiple-coil, rather than a single-coil with a high-tension distributor, and it is mainly for this reason that each part has been kept quite distinct in order to make it easy to adapt the system to individual requirements. Thus, when a multiple-coil is employed, a simple "commutator" is all that is required, whereas for use with a single-coil, a neat high-tension distributor has been constructed, which also embodies a low-tension contact-maker in the same casing.

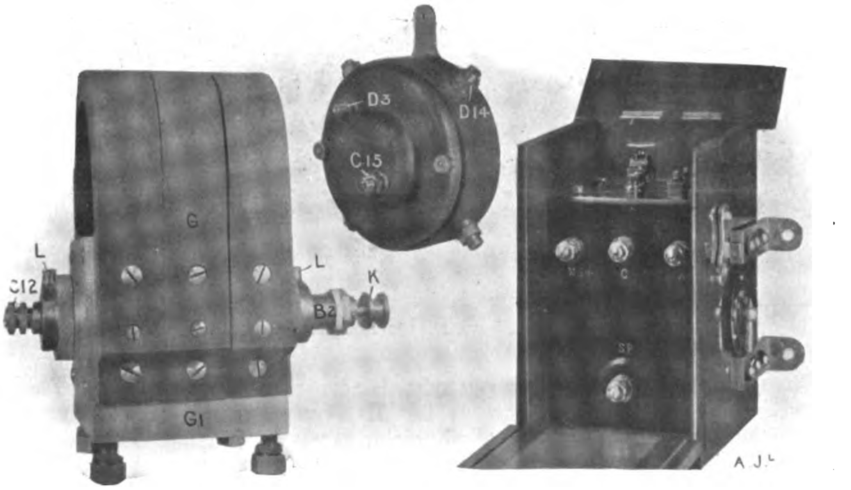


FIG. 1.—The Castle High-Tension Magneto System. View of the complete outfit consisting of magneto, single coil, and combined high-tension distributor, and low-tension commutator.

The net upshot, therefore, is that the Castle magneto *system* is virtually identical with ordinary high-tension systems using accumulators, for the only real difference is the substitution of a low-tension magneto in place of the battery, using the two ends of the armature winding as though they were the positive and negative battery terminals.

Electrically, the use of a trembler is less remarkable in this system than in one (like the Gianoli), where it is employed without a contact-maker. In the Castle system its position is exactly similar to what it is in any ordinary high-tension ignition from accumulators, for it is powerless to come into action until the "commutator" has closed the primary circuit. Although it is thus uninfluenced, as regards the instant of its operation, by variations in the voltage of the magneto, it has, no doubt, some regulating effect on the voltage actually induced in the coil. Rapidly as does the current regain its full value when switched on to the induction-coil by the contact-maker, yet for the moment it receives a check which it requires a certain period to overcome. With a well-balanced trembler, carefully adjusted to operate at a given current strength, there is therefore every possibility that this value will not be exceeded, no matter how much the actual voltage of the magneto may vary—the consequence being, of course, that the coil itself is protected against undue electrical strains under which it might be liable to break down. This issue gains its chief importance, however, from the fact that the same induction-coil (and same primary winding) is used for the alternative battery ignition which is specially provided for in this system. It has not generally been considered feasible to use one coil—or at any rate the same primary winding—for both magneto and battery ignition, and it is doing this that constitutes the real originality of the Castle system.

Orthodox general design has been followed in the mechanical construction of the magneto, and a very neat form of combined "commutator" and distributor has been made for use with the single-coil system. With multiple-coils the contact-maker is of the ordinary roller-contact type, already well known in connection with battery ignition.

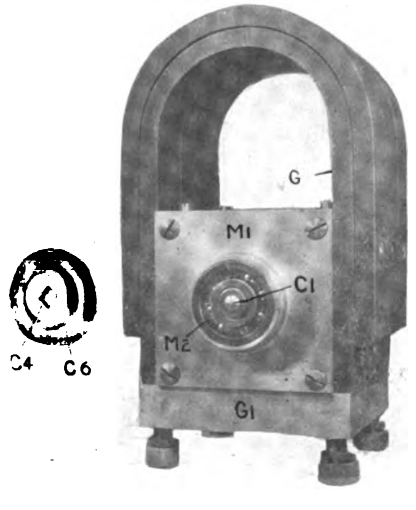

FIG. 2.—The Castle High-Tension Magneto System. View o the magneto showing the live end, C^1, of the Armature Coil, and the Collector Contact, C^4, which is carried in the detachable Screw Cap, C^6.

Our Illustrations.

Views of the magneto are given in Figs. 1, 2, and 3, and from these its simplicity will be obvious. A view of the single coil, with its distributor, is included in Fig. 1 in order to make that illustration represent a complete outfit, but the multiple coil and contact-maker, which are sometimes used instead, are shown separately in Figs. 5 and 6. In Fig. 4 the combined commutator and distributor is taken apart, while Figs. 7 and 8 show the usual diagrams of connections which accompany all these articles, and enable one system to be compared graphically with any other, besides facilitating, in the case of Fig. 8, the practical installation of the system on any ordinary vehicle.

The Magnets.

There is nothing about the horse-shoe magnets, G, to render them different from those usually employed. They are composed of six separate elements, arranged side by side in pairs, and are mounted on an aluminium base-plate, G^1, by means of screws, which are inserted from beneath and pass up into the solid cast-iron pole-pieces, G^2. Separate screws passing through the magnet limbs retain the pole-pieces in place, and the whole magneto is secured to the engine by four studs which project from the base-plate, G^1.

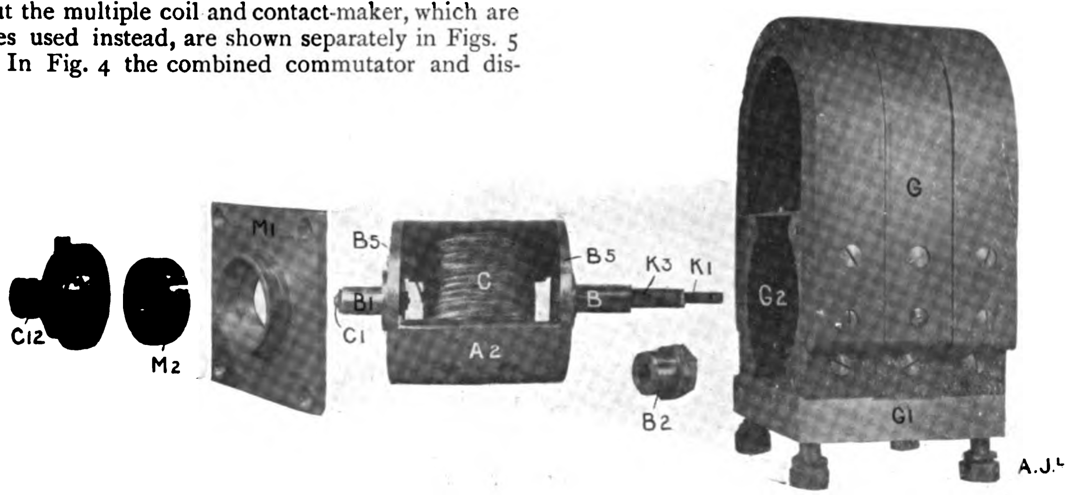

Fig. 3.—The Castle High-Tension Magneto System. View showing the component parts of the magneto in their relative positions. To dismantle the magneto into the state here represented it is only necessary to remove the Bearing Plate, M^1, by withdrawing four screws and to take the driving sleeve, B^2, off the other end of the armature shaft.

(*To be continued.*)

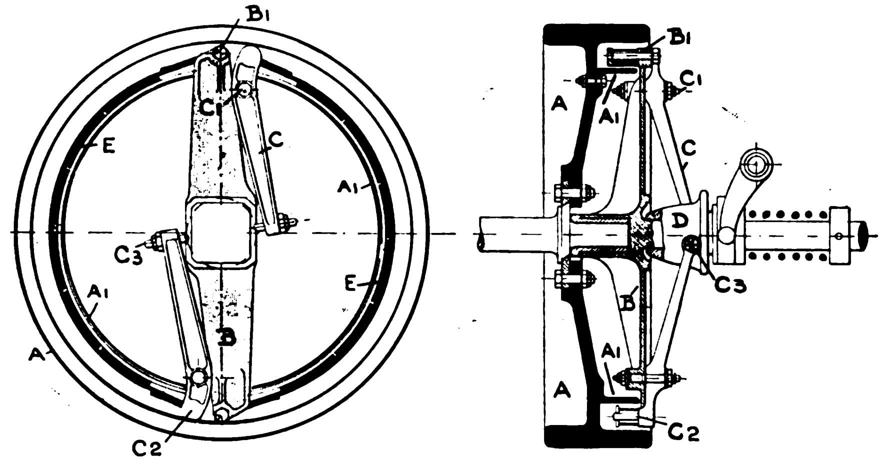
THE MORS CLUTCH.

On the new Mors chassis—exhibited for the first time at the recent Paris Salon—the main clutch is, it will be remembered from our Paris Show report, of a different type to anything which has hitherto been in general use. In principle it is merely a shoe-brake, although at first sight it resembles an ordinary band-brake in appearance. Our present illustration shows the details of its construction, but the clutch itself was also partly visible in a photograph which we published on page 1559 of our last volume. Bolted to the flywheel, A, is the drum, A^1, which is encircled by the halves of the brake, E. These thin brake-shoes are anchored, at B^1, to a two-armed spider, B, which forms part of the driven shaft, and, carried by the same member are the two operating levers, C. Each lever is attached to the free end of its brake-shoe at C^2, is fulcrumed at C^1 to the member, B, and rests its long end against the conical wedge, D. The wedge, D, is connected to the clutch-pedal, and is the means of tightening or loosening the brake-shoes about the drum. An adjustment, C^3, is provided on the end of each lever, but these, it will be noticed, require individual setting in order to make the two halves of the clutch grip equally.



THE MORS CLUTCH.—Elevation and transverse section showing the arrangement of the brake shoes, E, about the drum, A^1, and the method of operating them by means of the conical wedge, D, and the pivoted levers, C.

THE 1906 SIX-CYLINDER NAPIER CARS.—PART III.

The Transmission Gear.

CONCERNING the main-clutch it is hardly necessary to give any full particulars, because the clutch fitted to all these cars is of the same design as that of which we gave an illustrated description on February 4th of last year. Its compact form, and the comparatively small size of the fly-wheel that contains it, can, however, be seen in Fig. 3, and it will be remembered that it is somewhat like an ordinary internal cone-clutch having a self-contained spring, except that it runs in oil and has no leather facing. The metal face of the inner member is forced rearwardly against the outer metal member, squeezing the oil from between them, and there are pockets cut at intervals in the outer friction surface to allow the oil to escape or to return quickly as the case may be.

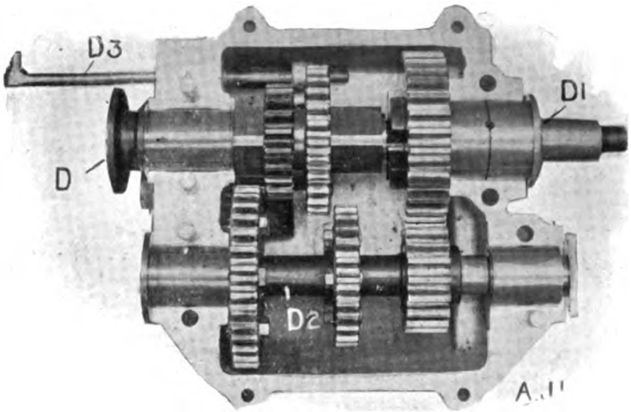


Fig. 4.—View, from above, of the Change-speed-gear employed on the live-axle Napier Cars. The upper portion of the Gear-box has been taken off, and the sliding Spur-wheels are shown in their neutral position.

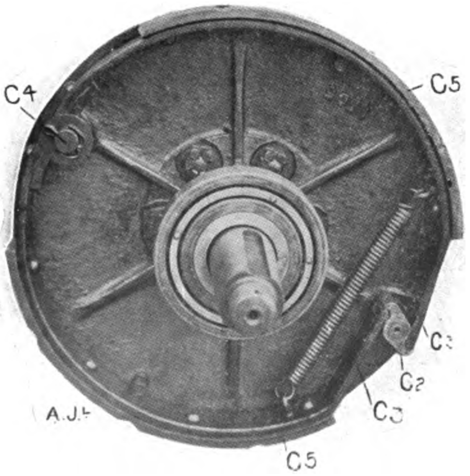

Fig. 6.—View showing one of the Hub-brakes on the 60-h.p. Napier Car. In this illustration the Road-wheel has been removed, and the Live-axle is seen from the end.

Fig. 4 is a view of the lower portion of the gear-box, with the spur-wheels in place inside it. The shaft, D, is that which is coupled up through a short propeller-shaft with the clutch, and the short shaft, D^1, is that to which the long propeller-shaft and the foot-brake are connected; a plain bearing carries the shaft, D, but the other three bearings in the gear-box are roller-bearings. It will be noticed that the shaft, D, is of very substantial proportions with a large square formed upon it for the two sliding spur-wheels that gives the first and second speeds. These wheels are controlled by a rod that is fitted into the upper half of the gear-box, for the rod, D^3, which is seen in Fig. 4, is merely connected to the "reverse" pinion—in the base of the lower casting. A direct drive is obtained on the third (top) speed in much the usual manner by clutching the second speed wheel direct to that upon the shaft, D^1, and the lay-shaft, D^2, is always in gear with that shaft. Simple, strong, and very compact is this entire mechanism, the three forward speeds in which are obtained by a single lever working over a plain quadrant, while a separate small lever is employed for introducing the "reverse." A neat inter-connecting device prevents the reversing lever from being moved except when the main lever is in its neutral notch. For the first speed, the lever has to be drawn rearwardly, while for the second and third speeds it is pushed forwards in two successive stages.

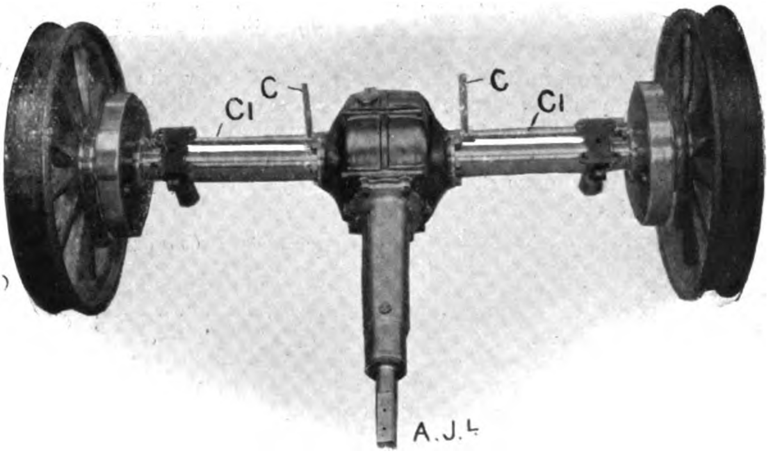

Fig. 5.—The Live-rear-axle of the 60-h.p. Napier Car, complete with its enclosed Propeller-shaft and Hub-brake mechanism.

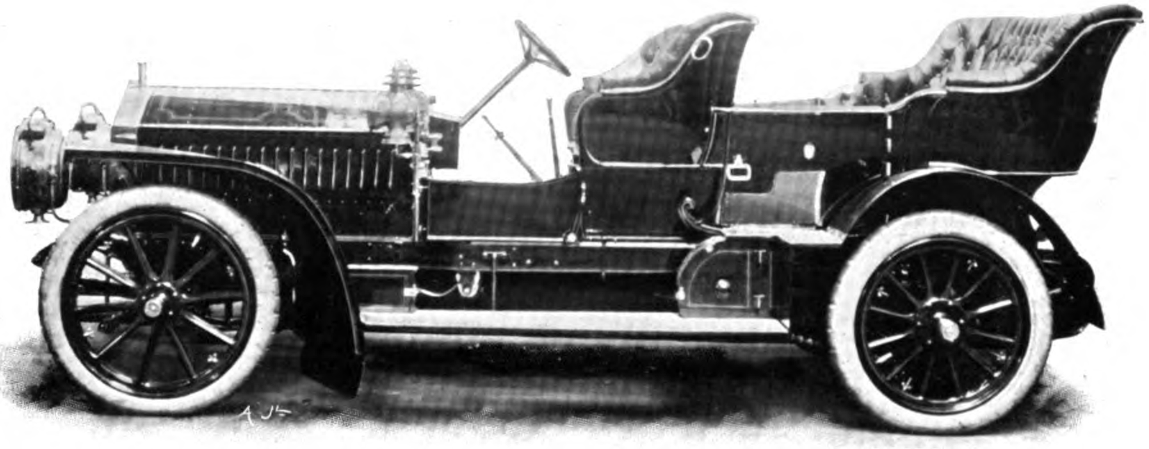
Usually the standard cars are geared to about 19½, 34½ and 52¼ m.p.h. at 1,600 revs. per min. for England, but can alternatively be geared to 27½, 48 and 72½ m.p.h. for the Continent.

The very neat appearance of the live-rear-axle, with its enclosed propeller-shaft and the brake mechanism for the hub-brakes is well seen in Fig. 5, while in Fig. 6—on a large scale—is an end view with the road-wheel removed to show the arrangement of the expanding brake-shoes, C^5. Inside the axle-tubes the live-shafts run in ball-bearings, but the wheels themselves take a bearing upon the outside of the axle-tubes, and also have ball-bearings.

For operating the hub-brakes, the compensating rods that pass rearwardly from just behind the gear-box are



Side view of the 40-h.p. chain-driven Napier Car.

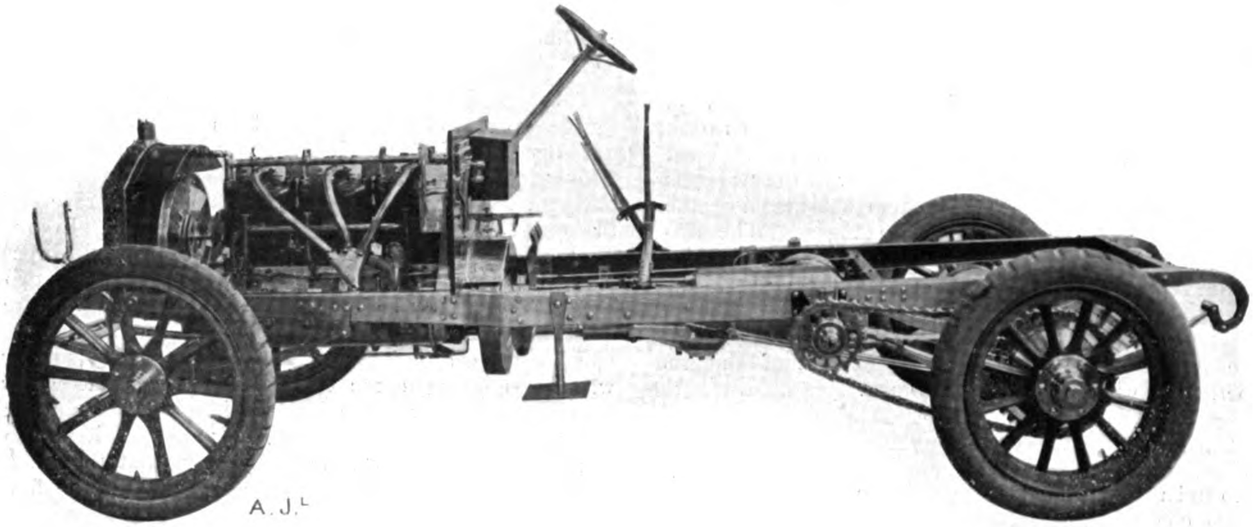


Fig. 7.—The chain-driven 40-h.p. Napier Chassis. Side view with the Bonnet removed, showing the 6-cylinder engine from carburettor side.

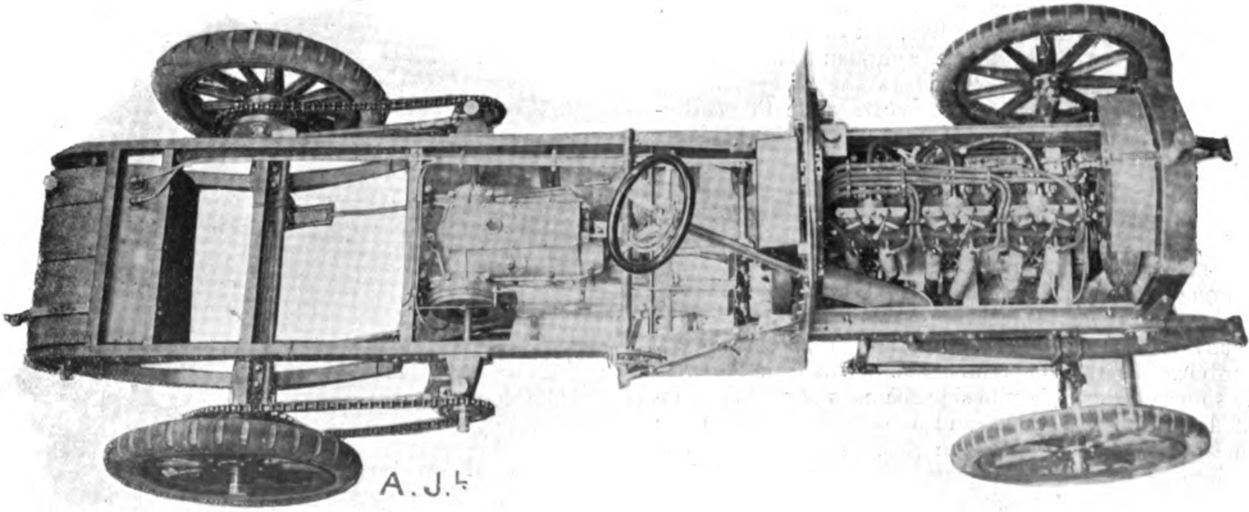

Fig, 8.—The 40-h.p. chain-driven Napier Chassis, as seen from above.

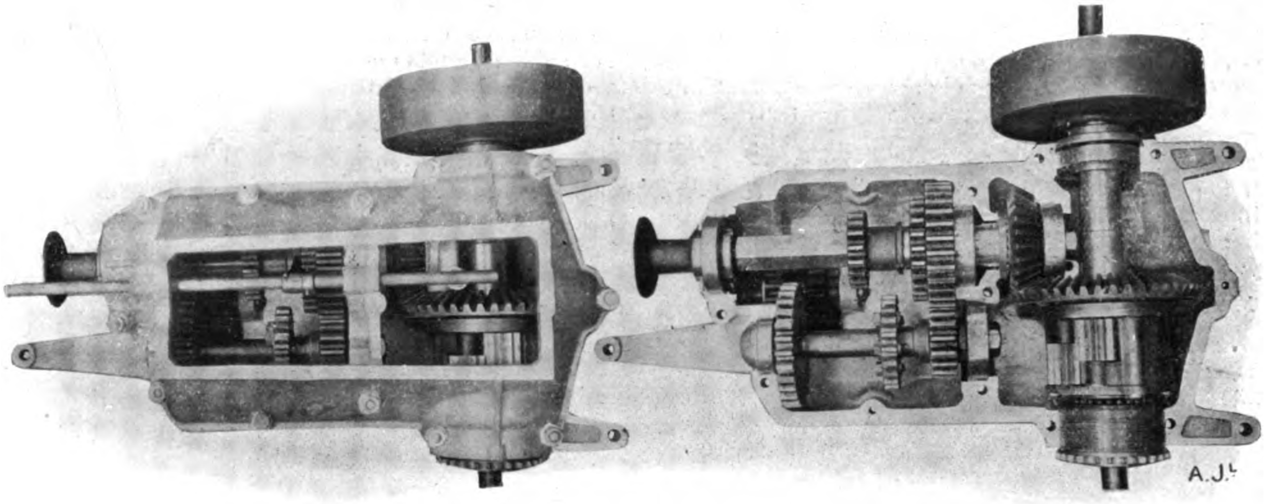

Fig. 9.—Two views of the Gear-box employed on the 40-h.p., chain-driven, 6-cylinder Napier Car.

connected up to the levers, C, and thus the shafts, C', are caused to rock when the brake-lever is drawn back by the driver. On the ends of these shafts are fixed specially shaped cams, C^2, that engage with the two ends of the brake-band, C^3, forcing them apart, against the action of the strong spring seen in Fig 6. The two halves of the brake-band are pivotted to the fixed pin, C^4, and renewable shoes form the friction surfaces. By this construction, a very powerful braking effect is obtained, but a very soft and gradually increasing action is ensured, in place of the fierce seizing that is experienced with some forms of brake.

The 40-h.p. Models.

So full a description was given by us last year of the 40-h.p. chain driven car, that comparatively little need be said about it now, although some minor improvements have been made since then. We, however, give two views showing one of the latest chassis—Fig. 7 being a side view and Fig. 8 a view from above—and we also reproduce in Figs. 9 and 10 photographs of the gear-box and of a hub-brake. The engine has, it will be remembered, mechanically-operated inlet-valves, but they are mounted above the exhaust-valves on the right-hand side, the six separate exhaust pipes that lead to the first silencing-chamber being on that side of the car, while the carburettor with its triple-branched induction pipe leading over the cylinder-heads is on the other side.

The gear-box has, as seen in Fig. 9—where it is shown both with the upper half in place and with that casting removed—a three-point support by which it is fixed to cross-members of the main frame, and both parts of the "through"-shaft, as well as the lay-shaft, run in ball-bearings. The spur-wheels are, in the main, arranged in exactly the same way that they are inside the 60-h.p. gear-box, but the differential countershaft that carries the sprocket-wheels for the side-chains is also accommodated (with ball-bearings and a ball-thrust) within the same box. Consequent upon this, the bevel-pinion is fixed to the short driven-shaft, and it will be realised from Fig. 9, that a second ball-bearing supports the extreme end of this shaft, behind the bevel-pinion. There is thus no overhang to set up any "dithering"; the end-thrust of the pinion is taken by a ball-thrust.

There is another constructional difference between this gear-box and that employed on the live-axle cars, for, instead of there being only one intermediate "reversing" pinion, there are two, and, instead of having a separate lever for introducing the "reverse," the one change-speed lever only is required. In our photographs, the gear is shown in its third speed (direct drive) position, but it will be understood that as the two sliding-wheels are moved forwards along their square shaft, the larger wheel first engages with the second speed wheel on the lay shaft, and then, after the smaller wheel has engaged the first speed wheel, that wheel comes into mesh with the foremost intermediate pinion; that pinion being shrouded on its front face, it is also caused to slide forward, the result being that the other intermediate pinion is brought into gear with the first

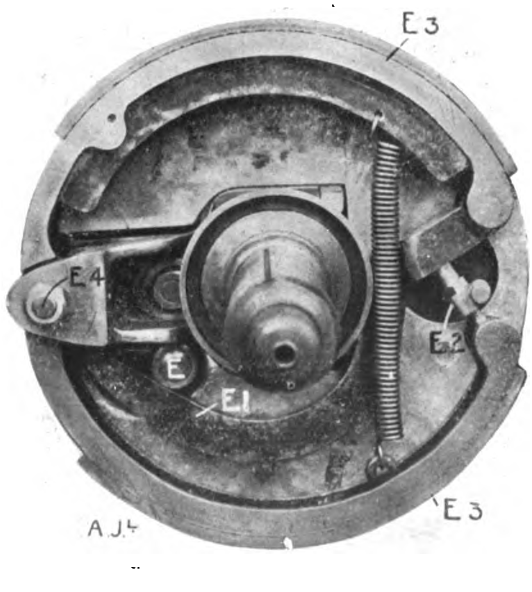

Fig. 10.—One of the internal expanding Hub-brakes, fitted to the chain-driven, 40-h.p. Napier Car. View looking at the end of the Rear-axle, with the Road-wheel removed.

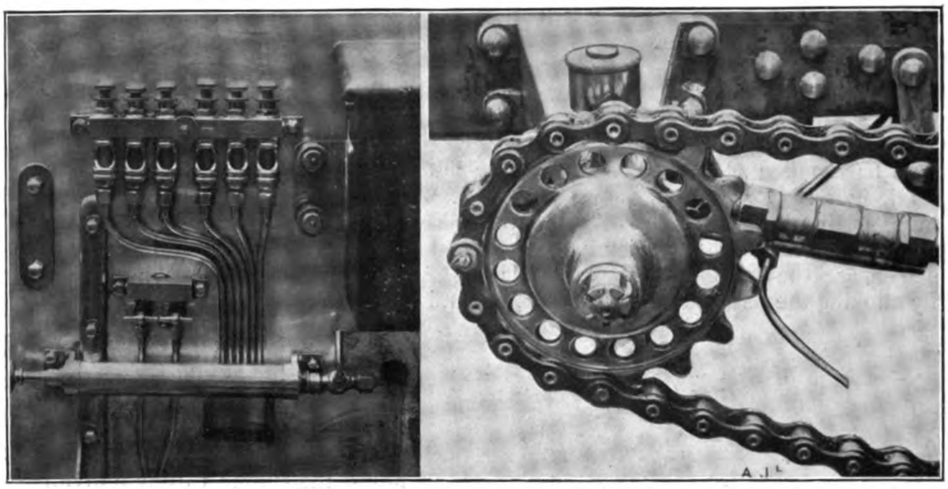

Figs. 11 and 12.—Two views showing the lubricating arrangements on the dashboard, and in the neighbourhood of the sprockets, respectively, for oiling the side chains on the latest 40-h.p. Napier Cars.

speed wheel on the lay-shaft. The differential-gear with its spur planet-wheels will be recognised in Fig. 9.

Referring to Fig. 10, the construction of the hub-brakes on this car can be easily followed. In this design it is the rock-shaft, E, that is actuated by the hand-lever, and the special cam on the end of this shaft that forces down the lever, E^1. This lever is pivoted to the upper brake-shoe, E^3, and there is an adjustable toggle-link, E^2, between it and the lower brake-shoe. In this way the lever, E^1, causes the brake-shoes to separate against the action of the spring, forcing the shoes outwardly against the surrounding brake-drum. Both shoes are pivoted about the fixed pin, E^4.

Quite recently, a new device has been adopted for lubricating the side-chains from the dashboard; this arrangement is well illustrated in Figs. 11 and 12. As will be seen in Fig. 11, there are two cocks fixed to the dashboard, just below the sight-feed lubricator, and from them pipes are led to the positions shown in Fig. 12. Oil can thus be fed on to the chains while they are running, and any tendency that they may have to become noisy can be instantly checked; the feed may either be continuous or intermittent, as desired.

For the live-axle 40-h.p. car, the same engine is used as for the chain-driven model, but the gear-box is identical with that on the 60-h.p. vehicle. It, however, is geared slightly higher than the chain-driven car (though considerably lower than the 60-h.p. machine), the gears normally giving about 17¾, 30, and 46 miles per hour as against 14¾, 27¾ and 44 m.p.h.

Conclusion.

Such then are the 6-cylinder Napier cars which have created so much stir in motoring circles during the past year or so, and particularly—in a more or less controversial form — quite recently. That they should have done so is by no means surprising when one considers the remarkable capabilities of *all* the modern vehicles that are now being turned out by the best known makers, and the extraordinary degree of perfection which has been reached so rapidly by the united efforts of those most interested in the motor industry.

So good are many of the 4-cylinder vehicles on the market that many people naturally deem it impossible to obtain anything better, and feel that the extra cost of a further couple of cylinders can hardly be justified in actual practice. Further than this, it could never have been a foregone conclusion that six cylinders could be made to run in such absolute unison with one another as to enable the engine to run as do those built by the Napier Company.

On the other hand, however, it is clear that for engines of the same power, those having six cylinders can be made with lighter pistons and need not have such heavy flywheels, it being fair to conclude, therefore that—so far as the weight of the reciprocating parts *per cylinder* are concerned —that the 6-cylinder engine ought to be able to run at a higher piston-speed, and that it ought to be able to vary its speed more quickly. There is, too, a further important point to be taken into consideration by those studying the question from a general point of view. At any load and at any speed, the force of each impulse (the maximum torque) is less than with four cylinders, and the torque required to overcome the negative work (compression) never reaches as high a value. Not only therefore can the engine run faster, but it can also run at slower speeds without the individual impulses being felt, while it also follows that the intensity of the driving strains in every part, from the crankshaft to the tyres, and the extent to which they fluctuate in a regular periodic manner, should be materially lessened. Less wear and tear should consequently take place throughout those portions of the car, while at the same time the life of the tyres should be prolonged appreciably. Apparently cost of production is the chief factor which can be urged against such cars, but obviously those who buy 6-cylinder cars require powerful vehicles, and do not object to the extra cost.

⊕ ⊕ ⊕ ⊕

"The Gentleman Chauffeur."

ATTENTION has often been drawn by this journal to the extent to which young men of good position are adopting the motor car profession, either as a livelihood or as a means of obtaining a wide outlook on life. An amusing instance in point is provided by the reported experiences of the present Bishop of Worcester, or perhaps it would be more correct to say of his lordship's wife Lady Barbara Yeatman-Biggs. The Bishop had engaged a gentlemanly and thoroughly capable young man as chauffeur, and Lady Barbara was making a number of calls in the episcopal car, when at one house included in her "visitation" she was surprised to see the hostess come out and shake hands with the chauffeur and invite him in to tea. This he declined, saying that at present he was only the chauffeur, but Lady Barbara, on making enquiries, found that he was a youth of excellent social position and an old friend of the family on whom she was calling.

362915

THE WINTON LUBRICATOR.

In our recent description of the new 25-h.p. Winton car, we referred to the Winton Precision Oiler with which it is fitted; we now give a description of this device, together with various photographs which we have taken of its component parts. This lubricator is designed to force oil under pressure direct to any number of bearings with which it may be connected, and its action is such that only one pipe is fed at a time—which ensures the clearing away of any obstruction temporarily choking the passage of the oil. In principle, the Winton lubricator is similar to the Albion lubricator, which we described in our issue of September 16th, 1905, but it differs from it in various details of operation. Inside the case, A, which acts as a reservoir for the oil, is a plate, A^1, carrying all the mechanism. Beneath this plate is the pump-casting, B, which has a conical face, B^1, in order to enable it to make an oil-tight joint with a corresponding seating on the bottom of the case, A. Oil is delivered, through a small hole in this facing, from the pump cylinder, B^2, immediately above it, and the plunger, C, itself is operated through the rock-lever, C^1, by the spring, C^2. There is only one pump, but there are, in this particular lubricator, eight feed pipes; in order to supply oil to each, therefore, the pump is rotated bodily, so that its delivery port comes opposite to each in turn. The lubricating motion can be effected from the engine by an eccentric rod mounted on a projecting end of a cam-shaft. The eccentric rod is coupled up to the crank, D^3, thus transmitting an oscillating motion to the bevel-wheel, D^2, which engages with the bevel-wheel, D^1, and this in turn imparts, through the agency of the free-wheel clutch, D^1, an intermittent rotary motion to the worm, D, and worm-wheel, B^3, the latter being directly connected to the pump-casting, B.

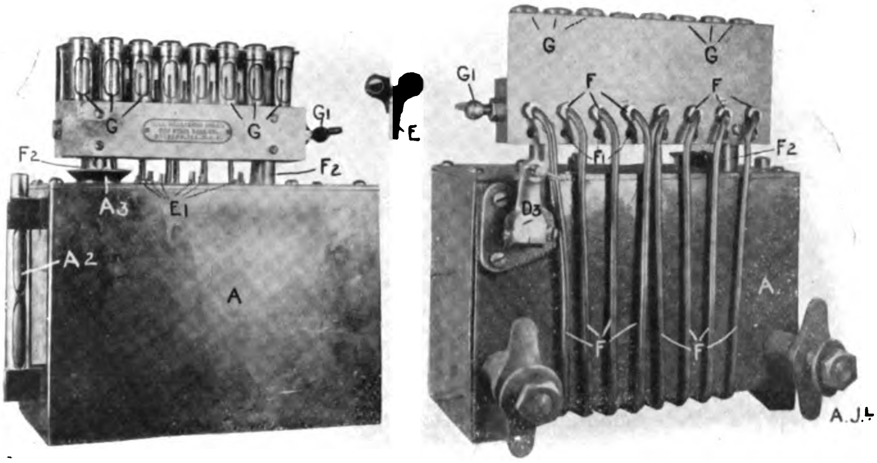

Fig. 1.—The Winton Lubricator.—Views from the front and back of the complete apparatus. Above the Reservoir, A, is the Sight-feed-fitting. Oil is delivered under pressure to each pipe separately, the mechanism being coupled up to the engine by a rod connected to the Crank, D^3. Between these views is seen the Key, E, by which the feed to each pipe can be adjusted.

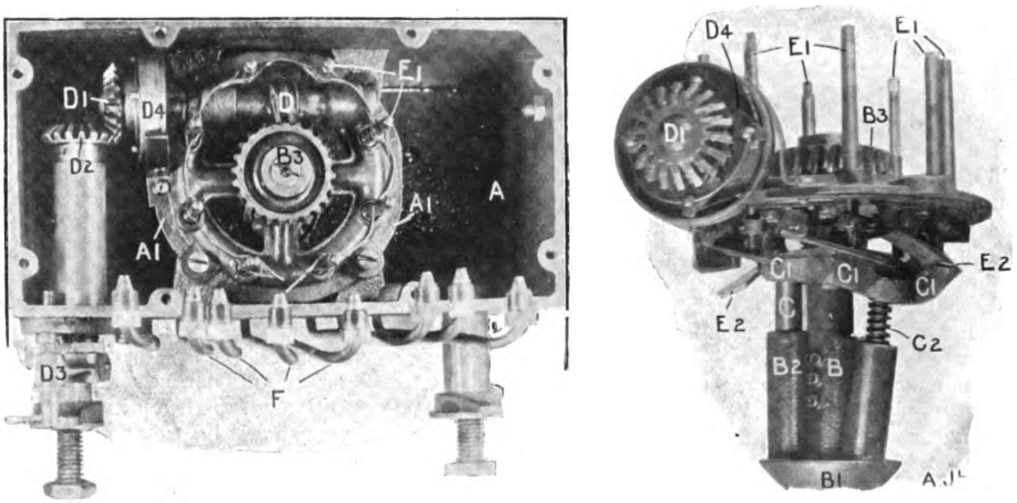

Fig. 2.—The Winton Lubricator.—View of the Interior, showing the mechanism in place; also another view (on the right), showing the mechanism separately.

As the pump-casting revolves, one end of the rock-lever, C^1, is caused to slide along the face of one of the inclined plates, E^2, in doing which it compresses the spring, C^2, and raises the plunger, C. Arrived at the end of the plate, it then suddenly slips off, and the spring, C^2, being thus released, forces down the plunger which delivers the oil under pressure to one of the feed pipes. By means of a small key, E, it is possible to instantly adjust the supply to any individual pipe, for by using the key to turn one of the spindles, E^1, which project through the case, A, the slope of the plate, E, connected to it can be altered, and the height to which the pump-plunger rises is varied accordingly.

From the bottom of the reservoir, the oil-pipes, F, pass up to a sight-feed fitting mounted above the case, A. Normally, however, no oil is visible in the sights, G, because there is a direct connection from the feed-pipes, F, to the delivery pipes, F^1, and it is only when the tap, G^1, is turned on that the oil-feed is visible. At such times, however, the oil does not go to the bearings at all, but only runs back to the reservoir through the drain-pipes, F^2, so that the tap, G^2, must not be left open longer than is necessary to ascertain that the pump itself is working properly.

AERONAUTICS.

Denmark Rivalling America.

If we can credit accounts which have appeared in the European Press of doings in Denmark, an aeronaut of the name of Ellehommer has built an aeroplane of which no particulars have been divulged, but one cannot help thinking that it is more or less on the Wright lines. The apparatus was provided with a motor and propellers, and was mounted by Herr Ellehommer, the motor was started, rose slowly in the air and advanced against the wind for a distance of 50 metres, when the intrepid experimenter stopped the motor and descended gently to the ground without damaging the apparatus in the slightest.

The Significance of the Experiment.

This experiment, if confirmed, is of very high interest indeed, and of very excellent promise of future accomplishment. Herr Ellehommer declares that he is so satisfied with the experiment that he hopes in a short time to be able to give a demonstration to which he will invite the Press of all countries. That he has accomplished a feat of the kind described we are the more prepared to believe, as it bears such a striking similarity to the first experiment made by the Wright Brothers with their motor-driven machine. In fact, it may be said that the position of the aeroplane at the present moment is rather like that of the motor bicycle when first introduced. It is certainly very advantageous for anyone who desires to ride a motor bicycle to have already been accustomed to riding an ordinary machine, but we are far from feeling sure that it is an *indispensable* preliminary condition. There is so much in knowing that the thing can be done. The experiment of Herr Ellehommer suggests that it may ultimately be found that preliminary practice in "gliding" is no more absolutely necessary than ability to ride an ordinary bicycle is indispensable for the man who aspires to the motor-driven machine. It is, in fact, quite possible, that to accomplish a successful glide from a hill top against a moderate breeze may be really more difficult than to learn to control a motor-driven aeroplane. The conditions, at any rate, under which the experiment can be successfully performed will be harder to attain. You must not only have the right aeroplane and the right kind of hill, but you must also have the right kind of breeze blowing against you. Where you have the motor on board, the latter requirement is, at any rate to a certain extent, eliminated. At any rate, we believe the success alleged to have been accomplished by Herr Ellehommer demonstrates what we previously maintained, viz., that half the difficulties of a new problem are eliminated when it has been proved that its solution is possible.

Experiments by Towing with a Motor Car.

To experiment with an aeroplane by having it towed by a cord from a motor car going at high speed is a form of tackling the problem which naturally appeals to a good many people, and we believe that we have ourselves on one occasion, at least, suggested it as worth trying. We are not now at all convinced that it is really a good method to adopt, because the towing cord, which represents the string of a kite, not only gives propulsive force, but also stability, and the problem, of course, is to accomplish stability while provided with propulsive force only. However, the experiment has been tried on the Ormond-Daytona beach, which is just the place one would select for trying it. Unfortunately, the aeroplane broke either itself or its rope—probably the rope—when raised to a height, by the motor car towing it, of 200 feet above the beach. It accordingly fell to the ground, but it is a remarkable evidence of the excellent nature of the Ormond-Daytona beach, and its suitability for experiment of this kind, that the experimenter did not suffer any worse injury than a severe shaking.

Recklessness not Necessary.

Of course, the experimenter had no business to go up 200 ft. What (if anything) he could have learned about the controllability of an aeroplane under such circumstances, would have been provided by keeping at a much lower altitude. If he was unable to do so it would have proved that his control was imperfect. He should have been able to keep his machine from going up so high; that is to say, if it was nearly as controllable as it ought to have been, instead of rising to a dangerous height like this he ought to have been able to maintain himself at from 20 ft. to 40 ft. in the air with a diminished pull on the motor car. The experimenter may think himself lucky in getting off so lightly. He says he intends to resume his experiments. We trust that if he does so he will be careful not to let his machine rise so high in the air, or if he is unable to prevent it from doing so, that he will arrange with the motor car to slacken speed as he rises.

Santos Dumont at Work.

M. Santos Dumont is getting on with his *helicoptere* and the machine is now actually being constructed in his workshops at Neuilly. It also appears that M. Santos Dumont has some intention of using an ordinary aeroplane, if we can speak of such novel machines as "ordinary." Should the experimenter give an equally favourable trial to both types of machine, we have little doubt as to which will emerge as the more successful. In the meantime the proposals which have been made to M. Santos Dumont to engage in an expedition to the North Pole with an airship of the navigable balloon type, if they ever materialise, will show whether that type of machine can accomplish what has hitherto proved an insoluble problem for all other methods of locomotion.

The South Pole not to be Neglected.

Proposals are now being put forward to attempt the conquest of the South Pole by somewhat similar means, and it is understood that the Count de la Vaulx is co-operating with Dr. Charcot, who has had considerable experience in Antarctic exploration, with a view to a combined attack on the Pole, in which airships, or more or less navigable balloons, will co-operate with sledges or other means of transport. The Count de la Vaulx, it will be remembered, has carried out a series of very instructive experiments, mostly on the Mediterranean, for the purpose of demonstrating how far ordinary balloons can be made navigable balloons by a triple system of floats travelling on the water, and also by means of motor propulsion. He is a thoroughly serious experimenter, about whom there is a conspicuous absence of "blague," and his participation in an Antarctic expedition is not likely to occur on anything but the most substantial and carefully considered lines.

Whether ultimately successful in its end or not, it will be almost certain to add considerably to our knowledge of the Antarctic problem. That a thoroughly serious and determined attempt will be made is shown by the fact that the Count de la Vaulx intends to spend some eighteen months in preliminary experiments and arrangements before actually commencing the real expedition, which he estimates will occupy some three to five years. Of this period some two years will be spent on the Antarctic Continent before the first attempt to reach the pole is made.

Count Zeppelin Again Unlucky.

COUNT ZEPPELIN took his navigable balloon out last week for the second time on Lake Constance, and passed over Ravensburg, Kisslegg, and Sommerstadt, ultimately descending at Allgau. A storm which got up during the experiments seriously damaged the machine, and it will be some months before it will be able to again take the air.

The Aero Club Wakes Up.

AMONG the results of increased general interest in aeronautics to which our efforts have, we hope, to some extent contributed, the Aero Club of the United Kingdom has appointed an influential council, consisting of the following members:—

Field-Marshal Earl Roberts, K.G., &c., Lord Suffield, Lord Howard de Walden, Lord Kinnaird, Lord Llangattock, Lord Montagu, Admiral Sir Charles Campbell, Bart., Sir David Salomons, Bart., Admiral Sir Edmund Fremantle, Admiral Sir E. Seymour, G.C.B., Gen. Sir R. Hart, V.C., Maj.-Gen. Sir Henry Colvile, Sir William Crookes, F.R.S., Prof. Sir Norman Lockyer, K.C.B., &c., Sir Hiram Maxim, Count de la Vaulx, Vice-President Aero Club de France, *Senhor* Santos Dumont (hon. member), in addition to the members of the committee, *ex officio*.

The club has further decided to hold dinners (at a moderate cost) once a month at the Florence Restaurant in Rupert Street, which will be open to members and their friends. The dinners will be held the first Tuesday in each month, after the committee meetings, and will be followed, we presume, by discussion on aeronautical matters.

Ill-advised Enthusiasm.

WE are as enthusiastic as any people can be as regards the solution of the aeronautical problem, and the conquest of the atmosphere. For that reason alone we desire to protest against the exuberant language of some people who allow imagination to outrun discretion. We refer particularly to the remarks attributed to Mr. Alexander Graham Bell, at a dinner of the Automobile Club of America, who predicted that the problem of aerial navigation would be solved soon, and that man would be able to dine in Halifax, Nova Scotia, and breakfast next morning in London. To do Mr. A. G. Bell justice, he refrained from saying precisely when this prophecy would be realised, but believed that the solution of the problem would come suddenly. It is possible, of course, that it may come more quickly than is generally expected, but probably those who contribute most markedly to its solution will not have their thoughts mainly concentrated upon dining in one place and breakfasting in another.

⊕ ⊕ ⊕ ⊕

Mr. Edge as Politician.

To his many other great gifts of organisation, motor car driving, and business management, Mr. Edge, as all who have heard him will be willing to admit, is a singularly able public speaker. He gave proof of his quality in this respect under distinctly disturbing circumstances at a recent political meeting at Reigate, where he spoke in favour of tariff reform, needless to say, as he understands it, *i.e.*, the imposition of tariffs imposed on finished manufactured products produced by foreign skilled labour. Without either agreeing or disagreeing with the views which Mr. Edge propounded, it is impossible to deny not only that he put them forward in his usual straightforward and convincing manner, but that he displayed a singular gift of dealing with a hostile or partially hostile audience. Received at first with interruptions so numerous that they threatened to render his speech abortive, he ultimately succeeded in getting the large and far from friendly audience almost completely on his side, and the closing portions of his speech were listened to with attention amounting almost to enthusiasm. This is not merely a personal triumph for Mr. Edge, but a marked example of his many-sidedness, which has been a source of admiration to all connected with the automobile movement and to many outside it.

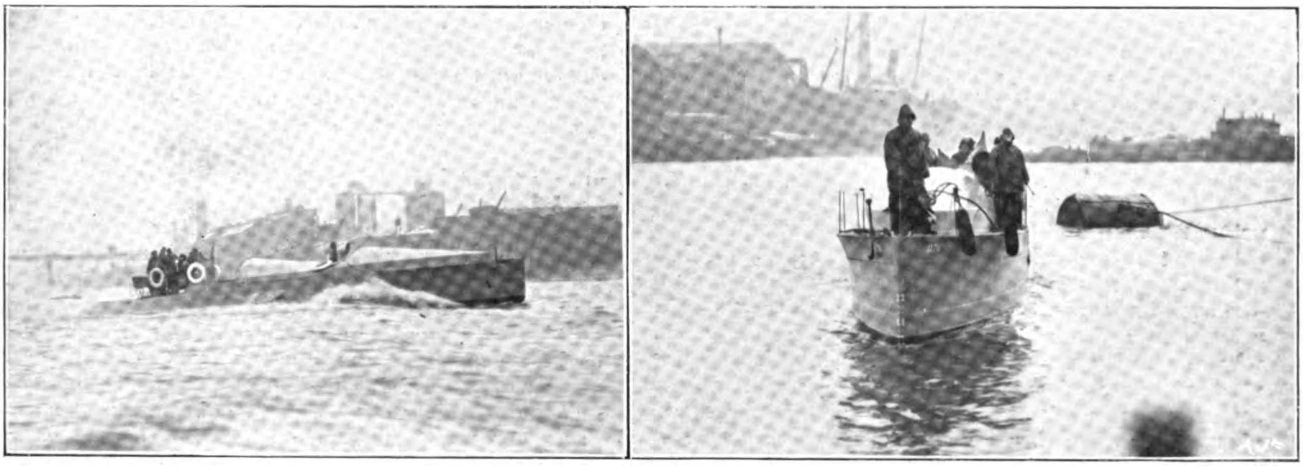
The Hilarious Burglar.

IF we went in for thumbnail sketches to illustrate the subject matter of our pages, we would place alongside of this paragraph a sketch of a burglar armed with the accoutrements of his profession—for example, "a jemmy sables on a field gules" dancing a jig, or otherwise giving expression to a feeling of satisfaction with things in general. For the burglar appears to have been having quite a grand time of it in the Walton district of Surrey, and this is locally attributed to the concentration of the police force on police traps—we beg pardon, motor traps [alias "coppermines" (*Punch*)]. It is, of course, impossible to expect policemen to be camping out on the roadside and disguising themselves as rustics, and sometimes as gentlemen, playing Pan's pipe under the widespreading branches of an umbrageous beech, or poking their heads out of pigstyes so as to be mistaken for the natural occupants, and then to be able to go home at night and exercise proper vigilance over the houses which they are paid by the ratepayers to protect from the enterprising followers of Bill Sykes. Small wonder that they have not been able to accomplish both tasks, and that the number of successful burglaries which have in consequence been carried out in the Walton district has caused a resident, Mr. Hume, to address the District Council and "call attention to the recent burglaries in the district, and move that the Clerk should ask for an increase of the police force in the district." This is highly instructive, for if such a proposal is generally adopted the cost of the police in England will soon become almost as great as in Ireland. Of course, we know that the fines raked in by police traps—we mean motor traps—goes to alleviate the rates; but if the result is that an increase in the police force is necessary so that we may have a day shift to man the police traps—we again beg pardon, the motor traps—and a night shift to look after the burglars, the advantages derivable from the fines inflicted on motorists will soon disappear. Perhaps the recognition of this feature of the situation will ultimately lead to more sensible management on the part of those responsible for the organisation of the police.

THE YARROW-NAPIER TORPEDO BOAT.

AFTER the remarks made by Mr. Yarrow on the virtues of the motor boat at the trials of Napier II., which we reported in our issue of March 11th last year, it was hardly to be expected that his famous firm would for long remain indifferent to the more utilitarian side of the high-speed motor boat industry. With such firms as Messrs. Yarrow, the utility of a boat is naturally more or less synonymous with its fighting capacity, and it came as no surprise, therefore, to learn that they had recently constructed a trial "second class" torpedo boat, which is propelled entirely by petrol engines. It is probably the most powerful petrol boat yet built for a "useful" purpose, and the constructors are undoubtedly to be congratulated on the manner in which it has shaped in the trials recently carried out in the Thames.

No one can say that the modern "second-class" torpedo-boat has what is popularly termed a "business-like" air. Its professional services require that it should be as inconspicuous as possible—a mere wasp, in fact, among the naval swarm. So with "1176"—as the new boat is at present known—there is very little of her, a turtle deck, a hurricane hood, and a streak of grey, and even these signs of substance are lost while the boat is yet skimming along in the near distance. It may be explained, for the benefit of those who are unversed in the precise appellations of each class of boat in a fleet, that torpedo-boats are of two classes, the primary difference between them being overall length. "1176" is 60 feet long, and is, therefore, in the "second class"; her beam is 9 feet, and she has already attained a speed over the measured mile of 26¼ knots. Previously, the best speed that could be expected from a boat of this type, propelled, of course, by steam machinery, was about 20 knots, so that there is thus a clear gain of some 6¼ knots by the mere substitution of the internal combustion engine for the steam plant. With this increase in speed, it may be mentioned, the second-class boat would be comparable with the considerably longer craft, which now figure in the first class. This advantage Mr. Yarrow attributes to the following causes:—"Firstly, the much lighter weight of the machinery of the internal combustion type as compared with steam, probably the saving in weight is 50 per cent.; secondly, the form of hull, which at these extreme speeds (for the displacement of a boat of this type) seems to enable it to rise on the surface of the water, and, as it were, to some extent slide upon the surface. This is made evident by the smallness of the surface disturbance of the water, which is very remarkable. Thus the portion of the power which is usually expended in producing surface disturbance, or what is called 'wave-making,' is utilised for propulsion." There is no doubt that this lucid explanation is upheld by appearance, even to the lay mind. The boat makes very little fuss either fore or aft, although, of course, she cuts through more "solid" water than did Napier II., which was a purely racing boat.

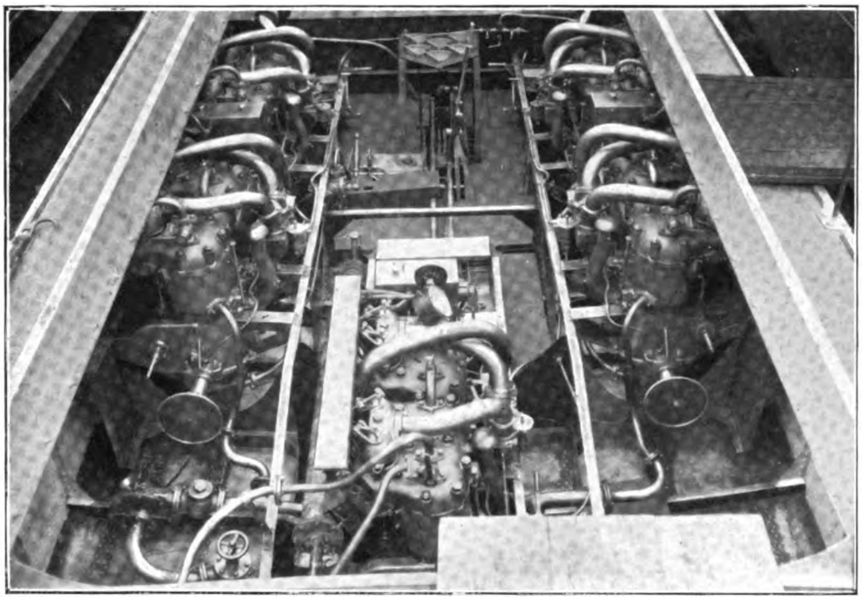


THE YARROW-NAPIER MOTOR TORPEDO BOAT.—"1176" at speed and at rest. On her trials this 60-ft. boat made a speed of 26¼ knots over the measured mile. When travelling her fastest, the fore part of the boat rises slightly out of the water, and at times about one-tenth of her overall length is entirely above the water line.

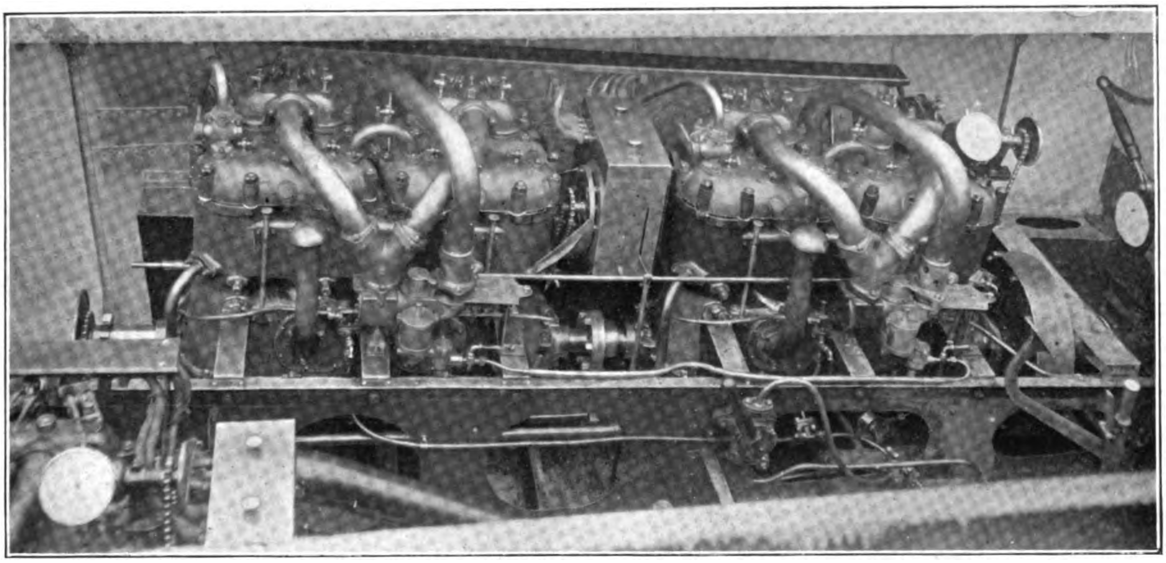
Our photographs give a very clear idea of the lines and construction of the new boat, although the skeleton condition in which she underwent her speed trials gives no indication of her final appearance when fully equipped with torpedo tube and quick-firing gun. The steel hull (the plates of which vary from 8 to 20 gauge in thickness) is divided by four bulkheads, those fore and aft being close up to the bow and stern respectively. In the central section is placed the propelling machinery, which consists of three engines, two of which have eight cylinders each, and drive the outside propeller-shafts, while the other engine—which lies further forward—has four cylinders, and drives the middle propeller. Each of the port and starboard engines in reality consists of two 4-cylinder units coupled together; thus, in all, there are five identical 4-cylinder engines which are similar to the Yarrow-Napier set exhibited at Olympia.

Although designed by Mr. Napier, and closely following well-known Napier practice, the engines are made by Messrs. Yarrow in their own works. All four cylinder jackets, together with the upper half of the crank-chamber are cast in one piece (of gunmetal), and cast-iron liners are forced into these jackets in order to form the cylinders. Bolted above them are the cylinder-heads, which are cast in pairs. The inlet-valves are placed over the exhaust-valves, and are operated by push-rods and rock-levers from the same cam-shaft.

In every respect these engines have been made mainly

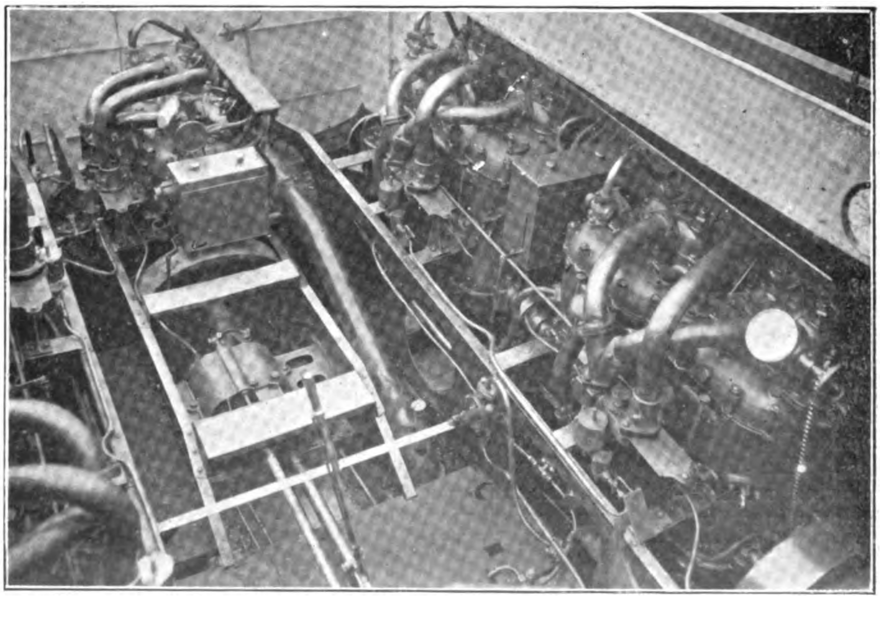


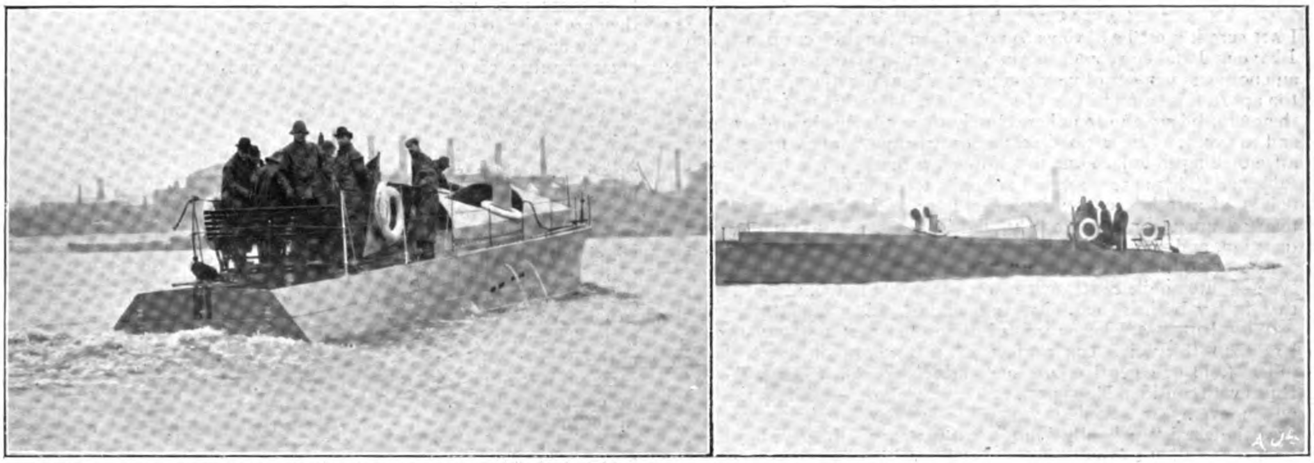
THE YARROW - NAPIER MOTOR TORPEDO BOAT.—View of the engine room looking aft. In the foreground is the central engine which is used for manœuvring and reversing, and at the far end the control table, which carries the ignition and throttle levers, is visible. Each of the "wing" engines consists of two four-cylinder Yarrow-Napier marine sets which are coupled together to form an eight-cylinder engine. The central engine, however, is a single four-cylinder unit. In all, there are, therefore, twenty cylinders, and the power available for going ahead is about 300-h.p.



THE YARROW-NAPIER MOTOR TORPEDO BOAT.—View of the starboard engine.

THE YARROW - NAPIER MOTOR TORPEDO BOAT.—View of the engine room, looking forward, showing the reversing gear behind the central engine. The plate bearers which support the engines are a noticeable feature in the construction of the boat. In appearance they are exceptionally light, but those for the "wing" engines run right through the bulkheads, and so add considerably to the general strength of the hull. The engines have gun-metal cylinder-jackets, cast in one piece with the top of the crank-chamber, fitted with cast-iron liners, separately water-jacketed cylinder heads are provided, and these are cast in pairs.





THE YARROW-NAPIER MOTOR TORPEDO BOAT.—Two views of the boat taken while she was making her trial runs in the Thames. The shape of her squat stern and her general broadside appearance are well illustrated by these photographs.

with a view to extreme strength and durability, and they are, therefore, somewhat heavy for their power—from the automobile standpoint. The total weight of the machinery is about 3 tons. Each 4-cylinder set develops about 60-h.p. at 1,000 revs. per min. There is thus about 300-h.p. available for steaming ahead, but only the central engine is used for reversing, as it is not considered necessary to complicate the machinery by fitting reversing gears to the other motors. For ordinary manœuvring in dock, too, the single engine is exceedingly handy, and altogether the disposition of the engines seems to have much to commend it, more especially since, even with only 9 ft. beam, the engine-room is anything but cramped. Cone clutches are employed behind each engine, but these are supplemented by jaw-clutches behind the wing engines in order to enable the propeller-shafts to be permanently disconnected from the crank-shafts when required. The reverse gear behind the central engine is of the ordinary sliding spur-weel type. When starting, the central engine only is got under way by hand, and the speed of the boat itself is relied upon to start the port and starboard engines by the turning effort exerted by the propellers as they are dragged through the water.

Fuel is carried right aft and the tank is separated by a watertight bulkhead from the rest of the boat.

Another “Argyll” Innovation.

Nothing is being left undone by the energetic managing director of the London Argyll Company—Mr. E. H. Watson—both to bring the well-known vehicles manufactured by his firm into prominence with motorists, and to ensure the continued satisfaction of all customers long after they have purchased their cars. Their business is, in fact, being carried out on remarkably enterprising lines, for not only can those who require cars actually select one from stock in the London show rooms, but now Mr. Watson is arranging for periodic examination to be made by his own inspecting engineers of every car sold by him, as long as it remains in use. Each owner will be given an opportunity of having his car thoroughly examined at intervals of about two months, and will on each occasion be supplied with a report specifying the condition of each and every part. Except as regards the actual travelling expenses to a distance, no part of the cost is to be borne by the owner of the car. There is, we think, little doubt that the majority of owners will thoroughly appreciate this beneficial innovation, for hitherto one of the only real difficulties which many people have experienced has been that of ascertaining whether their cars are being properly looked after or not. All motorists sooner or later realise that the life of their cars, and the dimensions of their repair bills, depend to an enormous extent upon proper care at the proper time, and that most heavy expenses which are incurred in replacements of parts, might in nine cases out of ten have been saved had the necessary adjustments been made at the time that they were required.

Although this new scheme involves a considerable and continuous expenditure of money on the part of the company—so much so that only a large firm doing an extensive business could undertake it—Mr. Watson has very carefully considered it in all its bearings, and is quite satisfied that it is commercially sound. The chief advantage to the makers is that they secure satisfied customers, that they are relieved of the work caused by trivial complaints from correspondents, and that they keep themselves in such close touch with their clients as to know at all times the exact respects in which modifications in design can be made to advantage when bringing out new models for the following year. From the purchaser's point of view there is, in addition to the more obvious merits, the very great advantage that little difficulty would be experienced in obtaining a good price for their cars, if at any time they wished to sell them; the periodical reports in themselves would go a very long way towards overcoming any of those difficulties which are at present met with when selling secondhand. It is just such schemes as this that do so much to popularise automobiles with the general public, and it is particularly satisfactory that a British firm should be giving so strong a lead in this direction.

Price of Fuel Goes Up.

As from January 19th, we are informed the price of all grades of naphtha, including motor spirit, has been advanced 1*d.* per gallon. Even with this advance, we believe the cost still remains below that ruling during the first few years of the industry.

THE TOURIST TROPHY.*

I AM sure it must be obvious to you all that the subject upon which I have undertaken to address you this evening is one that involves an enormous number of very complicated considerations, and is only too apt to raise a multitude of side issues. For this reason it will, therefore, be my aim to adhere closely to a clearly defined course, and to avoid, as far as possible, the many temptations that inevitably arise tending to induce one to follow cross roads which lead to pet subjects. There are, too, as I am only too painfully aware, some points of a rather contentious character which will have to be touched upon; but, fortunately, the Tourist Trophy is not a party question, and since this is not a political platform, I may admit at once that nothing in the nature of perfection can be claimed for any type of automobile contest whatever. When I tell you, gentlemen, that in my business capacity as technical editor of THE AUTOMOTOR JOURNAL I have received during the past four months no less than thirty-five square feet of manuscript in the form of letters from one gentleman alone, criticising the Tourist Trophy Rules with considerable vigour, and even violence—each square foot on an average containing 410 words—you will understand why I used the word "painfully" in my last sentence. It may, however, be a consolation to you to know that his criticisms are now partly directed against THE AUTOMOTOR JOURNAL for its narrow-minded short-sightedness in failing to take advantage of so much "cheap copy." And this brings me to a final preliminary explanation which it is only right to include in this brief introduction. Most of the time which I have been able to devote to a study of this subject has been on behalf of the journal with which I am connected, and I therefore feel that no apology is needed if I refer for some of my facts and figures to its pages. Personally, I have to thank the proprietors of that paper for permission to use the special tables which they have published when endeavouring to interest their readers in the Tourist Trophy question, as well as for the loan of certain photographic illustrations.

To begin at the very beginning, it is necessary to first ask whether, nowadays, anybody really wants automobile competitions at all, and even this question is somewhat of a "poser." Speaking in general terms, most manufacturers do not want to be bothered with them, but, on the other hand, I am inclined to think that the public undoubtedly wish for some such guide to enable them to decide which cars to purchase, and would even more strongly advocate and support such contests if they could be organised as purely sporting events, free from all trade influences. It almost appears as though we have reached a stage at which the motoring public would have been able to relieve the manufacturers of the cost and anxiety of all such contests if any thoroughly satisfactory kind of competition for touring cars had been well established on accepted lines already. Nothing of the kind has, however, hitherto existed, and consequently the private owner is still waiting for the trade to show him how to enter into friendly competition with his friends when they go for spins together. I think there can be no doubt but that all manufacturers would benefit largely if only they could find a way of overcoming this initial difficulty, and that they would then find it to be well worth their while to hold one great professional contest each year amongst themselves, in order to maintain a set of standards for the private motorists to work upon. It is difficult to conceive of anything that would tend to give a better education to the public on the proper management of their cars than this, for the man who habitually takes hills with his spark fully advanced, or frequently starts off on a day's run with his brakes partly "on," would soon learn why he—not his car—was at fault. It is, I think, quite safe to say that neither manufacturers nor their agents want to take part in any such events, and that most of them have only done so in self-defence in the past. I do not suggest that the local contests need even be held on precisely the same lines as the great annual competition, for clearly it would be impossible for the roads to be appropriated in the same way to suit their convenience. It would not, however, be difficult to draw up corresponding rules free from all such objections.

Assuming, then, that competitions are required for the reasons just given, it may next be maintained that they should be organised simply and solely for such cars as are built for ordinary use, and that the rules governing them should, so far as possible, rigidly exclude everything in the nature of special machines designed and built merely to win such contests. It should also, I think, be taken as an axiom that the rules ought to discourage any method of driving which is calculated to have an injurious effect upon the durability of the mechanism. We practically have to then consider what type of contest is most useful, and the first point that arises is whether it should be of short or long duration. Clearly, short duration trials are preferable if they can be rendered effective, for they more nearly approach the requirements of provincial clubs, they are easier to conduct in a thorough manner, and they are more readily understood by everyone. In the past, those lasting over a great number of days unquestionably had their overwhelming advantages, for not only did they enable a great number of people in out-of-the-way districts to actually see the wonderful "fire-carriages," of which they had then only heard rumours, but most cars were sufficiently unreliable to give reliability trials a chance of showing up their many weaknesses. I am well aware that even now there are those who advocate competitive runs over very long distances, or comprehensive trials lasting over a considerable period; but for all that I think I am right in saying that most men who have gone into the matter very carefully, or have had much experience in the organisation of such events, take a strong view in the opposite direction. To make such trials really useful, an extremely complicated and stringent set of rules would now-a-days be needed, while the nuisance that would be caused to other users of the roads would alone soon prove to be prohibitive. Then, too, some people would once more adopt some system of awarding marks for each and all of the features that are deemed to be most desirable in touring vehicles, such as was done in the Reliability Trials of 1902 and 1903, for instance, but they are apparently unaware of the heartburnings that inevitably result from any such arbitrary methods of determining the awards. It cannot. I think, be too widely recognised by all would-be trial-mongers that different owners of cars have very different ideas as to the relative importance of such matters as, say, silence, speed, and reliability, and that it is therefore hopeless, not to say misleading, to attempt to satisfy everybody by the adoption of any "mark" system. Everyone may agree as to what are the most desirable characteristics of a touring-car, but most people have very different notions about their relative importance.

Against short duration trials it is frequently urged that practically no estimation can be made, after so short a run, of the durability of the mechanism. If this were, however, the only respect in which long-distance trials are preferable, it seems to me that the advocates of such events are easily answered—unless they contemplate extending them over a totally impracticable period—because it will, no doubt, be very generally conceded that even a month of regular working would not produce any appreciable wear and tear on most of the best cars with which we are all acquainted. Apparently, the conclusion may, therefore, be arrived at that, whether an automobile competition lasts an hour, or whether it is drawn out to occupy a month, the relative durability of the various cars can only be taken into account by some less direct method than that of subsequent inspection. Personally, it seems to be very fortunate that any tendency for undue wear and tear to take place means that power is being wasted, even from the first, because it is, therefore, only necessary to place a big premium on efficiency of transmission, and we automatically give a great pull to the most durable car.

Even in the way of short duration trials, we certainly have a large number of possible kinds from which to make a selection. In the early days, when all cars were essentially "speed machines"—since none were anything like fast enough to satisfy ordinary users—there was no question as to what a motor car competition should consist of, for speed, pure and simple, was the one thing that everyone was thinking about. Now, however, things are quite different, most cars being able to attain sufficient speed to suit most people, and it is the hundred and one other merits of the best vehicles that are of real moment. How then are we to organise a competition which will automatically cause the best all-round car to be the winner?

Before attempting to answer that question, however, I want to bring into as prominent notice as possible an equally important matter which constitutes an even greater difficulty, and is, I sometimes think, apt to be entirely overlooked by many critics of the Tourist Trophy regulations. I refer to the classification of vehicles—a point which must essentially be considered at the same time, or even before, deciding on the precise nature of the actual contest. Now, what strikes me most forcibly in this connection is that the actual difference between two cars may quite conceivably have hardly any effect upon the cost of production, upon the average speed maintainable, or even upon the liability to break down when first turned out from the works in which it is built, but that nevertheless one of those cars may be cheap at a fairly high price, whereas the other may be dear, although sold for less money. Any form of competition is, therefore, bound to give very misleading results unless just these differences which constitute the true bases of comparison between such vehicles are placed at a very high premium by the rules, and unless the very greatest care is taken to equalise the chances of winning through superiority in any other respect. Conversely, however, it is obviously true that any competition which does bring out those real differences is just what motorists most require, for then an ordinary buyer who has no special knowledge on the subject is put in possession of the one kind of information which he otherwise finds it almost impossible to obtain. From this standpoint I deduce two salient conclusions. Firstly, that all cars which are allowed to compete against one another must be the same power, size, and weight; secondly, that the issues must not be confused by taking into account such things as prime cost, running cost, or, to more than a limited extent, silence and comfort, which are, after all said and done, matters that are well within the purview of all buyers, but have a different relative degree of importance to each individual.

---

* A Paper read at the Automobile Club, January 18th, 1906, by A. G. New, Technical Editor of THE AUTOMOTOR JOURNAL.

Returning again to the main question now under consideration—the best type of contest—we may, I think, begin by dismissing any idea of handicapping the competitors, for it is quite difficult enough to ensure that all the cars are similar, without attempting to organise a system by which differences of power, size and weight could be accurately compensated for. I am well aware that this suggestion is open to the criticism that existing cars are of every power, of all sizes, and of very different weights, but I see no reason why they should in future continue to be so, and I am not alone in hoping to see the time when a limited number of clearly defined types will be built instead. One might even go so far as to say that the Tourist Trophy Race would alone justify its existence if it were to have this desirable effect, for, as I hope to show presently, there need be no such close adherence to any type of mechanism, form of body, or weight of chassis as would tie the hands of progressive manufacturers, but we should yet obtain the full benefits of some definite standardisation of type. Frankly, I do not believe that any automobile contest can be run usefully if no such exact classification is adopted as a hard and fast basis, and I am all the more sorry to have been compelled to form this opinion because it leads to some extremely unfortunate facts. It is, indeed, the seed from which one tree of discord has already sprung, this season's fruits being the fine crop of letters that have appeared from makers and users of steam cars.

As to the exact form that the contest should assume, this is, it seems to me, a relatively unimportant matter that might even be allowed to vary in accordance with the conveniences at the time. One and all practically amount to the same thing if the principles that I have laid before you were to be adopted, because the competition would, at any rate, then resolve itself into a trial of the following things:—(1) Uniformly good running for a reasonable period without breakdown of any kind; (2) capability of maintaining a good speed up all the hills on the route; (3) efficiency of transmission; (4) free running of all moving parts. These things may, moreover, be said, I think, to include most of those which constitute the real differences between one car and another, to which I have already referred. For the big event of the year, and, indeed, for any competition that could be so arranged, I do not hesitate to say that a simple race is, for many obvious reasons, far preferable to all other alternatives. So evident does this appear to be, that I do not propose to labour the point, but would merely remark, on passing, that a straightforward race, free from technicalities, appeals to the imagination of everyone, and that high speed running imposes the more severe test on every portion of a motor car.

Hoping that I have now cleared the ground for a closer consideration of the Tourist Trophy question proper, and that, incidentally, I have justified the somewhat heavy expenditure of your time in so doing, I now propose to pass on to the existing regulations, and to show that the spirit which pervades them is quite in accordance with the conclusions that have just been arrived at. Simultaneously, too, it will be my endeavour to meet certain objections which have been made in various quarters. Primarily, the regulations drawn up by this club aim (1) at limiting the engine power that is available by allowing a certain quantity of fuel per mile to each competitor, and (2) at specifying a certain useful load (weight and shape) that has to be carried by each chassis. In this manner the regulations, therefore (3) limit the average speed which is attainable, although (4) they also award the Trophy to the car that covers the entire course in the shortest time. One particular class of car is thus defined most clearly, and so long as all the cars use the same kind of fuel and convert it into power in the same manner, they start upon an absolutely equitable basis, and one which will enable the most efficient to arrive first at the winning-post. The principle adopted does more than this, however, for it lays down no absolutely rigid specification which would rule out cars capable of developing slightly more or slightly less power, neither does it arbitrarily demand any particular weight of chassis. The result is that there is ample margin for variations in these respects, although a more powerful engine must also be more efficient if it is to benefit by its additional size, and a heavier chassis must show the advantages of its greater weight by the manner in which it reduces friction. Otherwise, the more powerful engine may have to be run at much below its normal power if the car is to complete the course without running short of fuel, and the needless weight of the heavier chassis will also have the effect of handicapping the competitor. In either case, however, the car could reach the winning-post, unless the power or the weight were greatly in excess of what they should be, for it would only be necessary to drive it at a much slower speed than its more happy rivals, and the fuel consumption per mile would be reduced sufficiently.

This fact brings us right up to what I consider to be the best feature of the "fuel comsumption" basis as a means of limiting engine power. Briefly, it prevents the engines from being driven to death merely to enable a car to win the race, and it does so because an engine takes considerably more fuel when run at an abnormally high speed, but it only develops comparatively little more power. If, as some would have us believe, it were better to base our standard of power upon cylinder dimensions, there would not be this restraining influence upon the drivers, and this fact is, to my mind, quite enough in itself—although there are many other strong adverse reasons—to condemn "cylinder capacity" or "piston area" as substitutes for "fuel consumption." The main reason why the speed of the car affects the fuel consumption so greatly is because of the extraordinary effect produced by "windage," although I do not suppose that one motorist in a hundred fully realises the extent to which the power of his engine is employed in forcing the car through the air. But irrespective of car speed altogether, the fuel consumption of a petrol engine is enormously increased in relationship to the power developed as soon as a certain reasonable engine speed is exceeded. Both these points are of so much importance that I may perhaps be excused if I break off for a moment in the main thread of this paper to give a few figures concerning them.

I cannot do better, I think, than refer to the full load results of some tests which were made last autumn with a slow-speed engine and with a high-speed engine in order to show the fuel consumption per brake horse-power at various speeds; these appeared in THE AUTOMOTOR JOURNAL on October 14th.[*] When the former engine was run up to 1,200 revs. per min., the petrol consumption per horse-power was just double what it was at 800 revs. per min., while with the high-speed engine it was four times greater at 1,700 revs. per min. than it was at 1,000 revs. per min. At very low speeds the efficiency is not so high as it is at what may be called the "normal" speed, so that there is nothing to be gained in the Tourist Trophy Race by running an engine at an absurdly low speed, although there is—as is shown by these figures—everything to be lost by letting it "race."

As regards "windage," the table which will now be thrown on the screen gives, in a very striking form, a good idea of the retarding effect of the air on a car. This table was also prepared and published by THE AUTOMOTOR JOURNAL,[†] with a view to its being specially applicable to the Tourist Trophy, the figures being calculated from assumed data of an approximately correct character. It is, for instance, assumed that the car weighs 2,400 lbs., and that the effective cross-section is equivalent to 12 square feet (flat). Time prevents me from saying very much by way of explanation of the whole table, and I must therefore restrict myself to merely extracting a few figures. In the fifth column it will be observed that if there were no such thing as windage, the car in question could, with only 12-h.p. available on the road wheels, attain a speed of 224 miles per hour on a down grade of 1 in 60, whereas column 8 shows that in reality the power needed would be 548-h.p.; in reality, too, the speed attainable, in practice, with 12-h.p. is only 39½ miles an hour (*see* column 9). The manner in which the amount of power absorbed by windage goes up as the car gathers speed, is brought out very forcibly by comparing columns 9 and 13 together, no less than 234-h.p. being needed for windage alone at 114 miles an hour, while at 71 miles an hour it is 57-h.p., at 50 miles an hour it is 20-h.p., at 32 miles per hour it is 5·2-h.p., and at 21½ miles per hour it is only 1½-h.p. Even if such a car were to fall, end on, over a precipice, it would only attain a speed of 200 miles an hour, for the windage would at that speed exactly counterbalance its entire weight.

Briefly pointing the morals that engines should be kept running at a reasonable speed, but certainly ought not to be "raced" while running in the Tourist Trophy Race, and that any indulgence in very high speed driving of the cars is wasteful from the point of view of "windage," I can now resume the main line of my subject.

The further merits, and also the demerits, of the "fuel consumption" basis (for limiting power), demand attention next, particularly as there is one most serious drawback that can only be removed by giving it the very widest publicity that it is possible. Advantageous, I think, are the facts that the primary principle on which the Tourist Trophy is based leaves designers quite free to make even the most radical improvements in engine construction, and that it takes into account the efficiency of everything, from the fuel tank to the tyres on the road wheels. Disadvantageous to some extent are the facts that too much importance is, perhaps, attached to the economy of the carburettor, and that there is a decided advantage to be gained by adopting undesirable methods of control, but these are, it seems to me, comparatively minor evils, since they only affect easily replaceable small parts, and are palpably adopted temporarily for a well-understood purpose. The one great drawback is, however, that the public are apt to regard the Tourist Trophy as a fuel-consumption contest pure and simple, and to run away with the idea that the main object of the Automobile Club has been to reduce the cost of petrol. Unfortunately, there is just sufficient in this notion to make it gain credence; but, on the other hand, no private owner need bother himself enough about his petrol bill to make him take much interest in any such competition. The difficulty, then, is to bring home to the public the real significance of the contest, and, in the first place, to make all motorists understand that reliability, durability, flexibility, and good all-round capabilities are the things aimed at. Once it is understood that the race is quite as much a *tyre*-consumption contest as it is a fuel-consumption trial we shall have overcome that which is most likely to endanger the success of the Tourist Trophy type of competition.

---

[*] See pp. 1268 to 1270 for the results of these tests, and p. 1116 (Sept. 9th) for the tabulated figures obtained from road trials with various cars.

[†] See p. 1305, October 21st last.

No attempt can be made to deal in any detail with the many other important provisions which were included last year, and have still been retained in the regulations, for it would take too long to do so. It is, I think, sufficient to say that there are many excellent clauses for compelling the competing cars to be ordinary *bonâ fide* touring vehicles. What is of great interest, however, is to note the wide differences in size between the engines on the various competing vehicles, and also to observe the average speed and the fuel-consumption figures that are available from last year's race. For the purposes I cannot do better than bring before your notice two more tables that were prepared and published by the journal with which I am connected. The first[*] of these gives the leading particulars and chief dimensions of the cars which were entered. Referring to the tenth and eleventh columns, we find that the cylinder capacity of the engines varies from 49 cubic inches per revolution (44,000 cubic inches per minute) to 122 cubic inches (122,000 cubic inches per minute), while the normal speed of the cars on the top gear differs as much as from 23¾ miles per hour to 45½ miles per hour. The other table[†] gives the results of the race, the ninth column from the left showing the average speed maintained, and the sixth column from the right indicates the fuel-consumption in miles per gallon. Of the eighteen cars that finished, the slowest did 27·2 miles per gallon at a speed of 23 miles per hour, while the highest consumption was 22·5 miles per gallon, and the speed of the winner was 33·9 miles an hour. That such enormous variations should be found is doubtless only natural, considering the novel character of the competition, but I venture to think that this fact alone is an ample proof of the great utility that the Tourist Trophy has been already. Many manufacturers have freely admitted to me that they obtained more valuable information through the work carried out by them in connection with this race than they had from any previous contest. I think it is quite safe to conclude that the competing cars this year will much more closely resemble one another both in power and speed capabilities, and that a very marked all-round improvement will be found in the average car of the particular type that is specified by the existing regulations.

And now I come to the vital question as to whether this type of contest has, in the light of last year's race, proved a success or a failure. From the actual results it is, of course, obvious that quite a number of cars did unexpectedly good performances, no less than fifteen making an average speed of over 25 miles an hour over the entire distance. The route was by no means an easy one, although the weather conditions were extremely favourable. Numerous corners, many of them extremely sharp, rendered frequent pulling up necessary, and the narrowness of the road in a number of places made passing anything but easy. The rough contour[‡] which is given by one of the lantern slides lent by THE AUTOMOTOR JOURNAL, shows that the gradients are quite sufficiently steep to impose ordinary touring conditions, while the tables that accompany it bring to light the fact that the up grades are steeper (being only 18 miles long) than the down grades (23 miles in length), and that only about one-fifth of the circuit (11 miles) is practically level.

But the real point is whether the winning car, and those which ran it close, are thoroughly useful touring vehicles, or whether the race has merely enabled some specially-built speed machines to come out triumphant. Some would have us believe that the whole system on which the contest is based must be far from satisfactory, since the Trophy was won by an unconventional type of engine. Many of these good people, however, would say the same thing if a 1908 car could have suddenly put in an appearance and have swept everthing before it, for, unfortunately, fashion—and often sheer prejudice—has become quite the ruling spirit with the motoring public of to-day. There is nothing like practical trial in such matters, however, and therefore I determined to satisfy myself on the subject if possible, and to ascertain by personal experience whether there were anything of the "freak" about the winning Arrol-Johnston, or about the Rolls-Royce car, of which one came in second. To cut a long story short, I have been absolutely delighted with the capabilities and controllability of both types of vehicle, and am quite convinced that for good all-round touring work they represent the best that has been done in the construction of that very useful size of automobile. I have now driven the winning car a total distance of about a thousand miles, in all sorts of weather, in the London traffic as well as in the open country, and have similarly driven the higher-geared Rolls-Royce a distance of some 250 miles. In neither case was the car in any way under the supervision of the makers, and I need hardly say that I had no mechanician. Crawling through the traffic, or starting from rest on a direct-drive gear which is yet sufficiently high to break the law to the tune of over 150 per cent.—if one did not happen to be a law-abiding citizen—is a simple matter with both these vehicles, and even a member of the Guildford Bench would appreciate being able to maintain 19·9 miles an hour up very steep hills. Personally, it seems to me that if the Tourist Trophy is responsible for the production of such "freaks" as these, the more we have of it the better it will be for all motorists. It will, in my humble opinion, have done a good deal even if it only breaks down the reactionary feeling that exists against unconventional types of car, merely because they do not happen to be fashionable.

To my mind, the only pity is that we cannot extend the useful field of the system by instituting similar events both for smaller and for larger cars. The difficulty is, of course, purely one of organisation, and is chiefly due to the lack of a clear course for a longer period than can be arranged in the Isle of Man. Just in the same way that we now hold the race for chassis of such power as to run 25 miles on the gallon, taking a useful load of 1,125 lbs., so we could have one for lower-powered chassis carrying lighter loads on a consumption of 35 miles per gallon, and another for highly-powered ones taking greater loads on an increased fuel allowance.

Although fully realising that I have already trespassed on your good nature by the length of this paper, a word or two should, I feel, be said in conclusion concerning the probable effects of the alterations made in the rules for this year. Generally speaking, it does not seem likely that they will materially affect the results, and I think that they may be regarded chiefly as a means of preventing certain weak points in the previous rules from being taken advantage of by any competitor. Thus, for instance, the number of "speeds" in the gear-box is limited to four, and at the same time the maximum and minimum gear-ratios are restricted in an indirect manner. A multiplicity of "speeds" might unquestionably prove beneficial to a competitor, since his engine could be kept running at a more efficient mean speed throughout the race, and, for the same reason, it would pay him to make the first speed as high as the steepest portion of the actual circuit would permit. Now, however, his first speed must be low enough to climb a hill of 1 in 6, and his top gear—which might otherwise have been excessively high for travelling downhill—must be low enough to be used at 12 miles an hour on a level road; the available range of gearing is consequently such as to be suitable for ordinary touring. (As a matter of fact both the Arrol-Johnston and the Rolls-Royce vehicles of last year can easily conform with these new requirements.) Some of the modified rules tend, however, to reduce the average speeds at which the course can be covered, but how far further improvements of a general nature, coupled with the greater attention that has now been concentrated on carburettor design, on petrol gauges for the fuel tank and on shape of body (to reduce windage) will compensate for the, reduced fuel allowance, and for the increased weight that has to be carried, remains to be seen. The race this year is, at any rate, sure to be quite as interesting and exciting, if not considerably more so, than it was last year. Certainly the club are to be most heartily congratulated on the success of their "all-British" and entirely novel type of contest for touring cars.

Mr. W. Worby Beaumont occupied the chair, and, after moving a vote of thanks to the lecturer, called upon Mr. Lyon Sampson to open the discussion. Mr. Fred C. Coleman then followed, and in an extremely able speech urged the Club to maintain a sporting attitude in the organisation of all its automobile events. Other speakers included Messrs. J. S. Napier (the winner of last year's race), Claude Johnson, Percy Northey, and R. Royce (the driver and builder, respectively, of the car which secured second place).

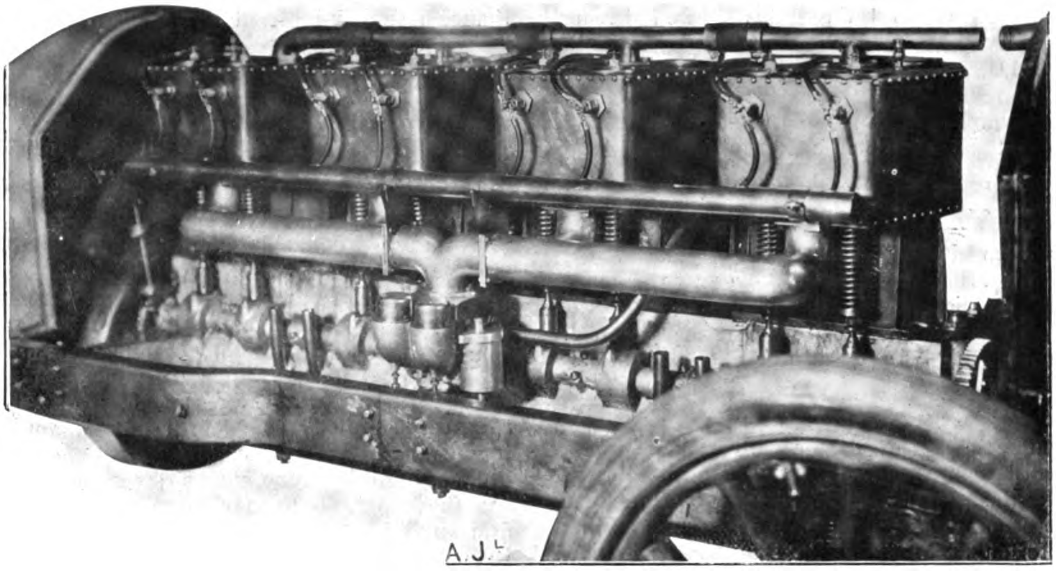
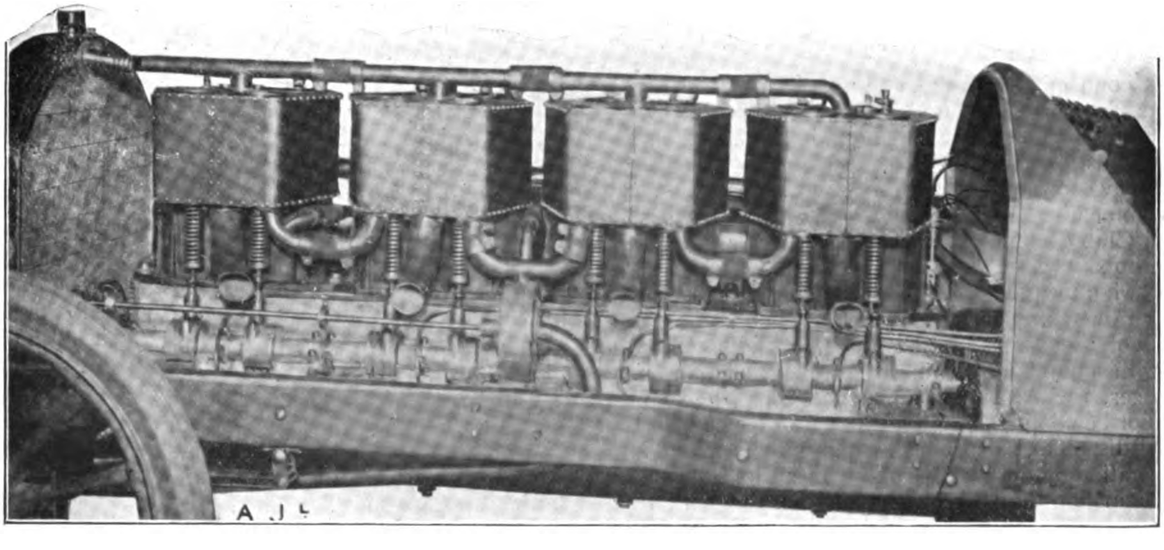
RACES, RECORDS, AND TRIALS.



The 8-cylinder "250-h.p." Vanderbilt Racer which was entered to take part this week in the Florida race meeting at Ormond-Daytona Beach. View of the engine from the "off" side, showing the special carburettor and the branched induction-pipe. Each pair of cylinders has the water-jacket formed by sheet-copper, the inlet-valves are all arranged on the right-hand side with ignition-plugs above them, and there are auxiliary ignition-plugs (connected up in parallel with the other plugs) passing through the sides of the inlet-valve-chambers. As we have previously mentioned, M. Francois Richard is responsible for the design of this powerful monster, which is, we learn, geared to a speed of 152 miles an hour.

Ormond-Daytona Races.

Up to the time of going to press, little news had come through from Florida of the doings at this annual race meeting on Daytona Beach, which started on Monday last. In preliminary essays, a Stanley steam "freak" is credited with having covered a mile under the half minute, and Clifford Earp is reported to have touched 31 secs. for the distance. For full official times in the programme, however, we have to wait—mainly first heats and minor events were down for the first two days' racing—but, before the start, trouble had already been reported with the wonderful Vanderbilt monster. Amongst the early races was the Dewar Cup (1 mile). The Stanley car secured this in 33 secs., although in a heat the same car was timed for 32½ secs., a new record, and later in the day further reduced this record time to 31⅗ secs.



View, from the "near" side, of the 250-h.p. engine on Mr. A. G. Vanderbilt's Racer, showing the arrangement of the exhaust-valves, of the short exhaust-pipes for each pair of cylinders, and of the circulating pump, with its water-pipe connections to and from the cylinder-jackets and the carburettor-jacket. This engine appears to have been built in Mr. Vanderbilt's private garage in New York.

Lancia, on his Fiat, was first in the heavy-weight cars, making for the mile 37 secs. One disappointment we learn is, that no White steamers are entered—as the makers were not able to arrange for their racers to go over to Ormond. Webb Jay and his spirited driving will be missed.

One of the Darracq racers was announced to be over weight, and, therefore, Hemery, in spite of the extraordinary exertions which he had made to get the cars there in time, is reported to have scratched the entire Darracq team.

Milan Tourist Trial.

It has been decided that this trial, under the auspices of the Milan A.C., will be over 4,500 kiloms. through Italy, starting from Milan, in 11 stages. An average speed of 30 kiloms. per hour must be maintained, the maximum allowed being 40—the Italian legal limit.

Grand Prix of the A.C. de France.

As, no doubt, the course will be early visited by prospective English competitors and many British tourists, who may take this picturesque country *en route* to some more southern point, it may be of interest to note that the chief hotels at Le Mans are de Dauphin, de France, du Simon, de Paris.

An early result of the selection of the course is the foundation of the Sarthe Automobile Club, with M. Singher, one of the prime movers in advocating the choice of this circuit, as first president.

Circuit Européen.

Following the International conference of clubs interested in this event, which was held in Berlin on Saturday, similar meetings will be held subsequently at centres of other leading Continental countries, in order that the success of the trial may be assured throughout every country which will be traversed. It has been decided that the trial shall take place in August, and that "observers" on each car shall be changed upon reaching each fresh country, in order that there may be no language difficulties amongst the competitors.

French Voiturette Contest.

In connection with the Voiturette Trial, which took place in November last under the auspices of *L'Auto*, the performances of the competitors in which were published by us in our issue of December 2nd, the A.C. de France have now announced an important decision. It will be remembered that soon after the conclusion the French Club declined to officially record the times of the competitors owing to certain difficulties which had arisen owing to the strewing of nails on the road, and although it was suggested by the organisers that the portion of the contest which was so maliciously interfered with should be eliminated from consideration by the judges, the A.C. de France held that this course could not be adopted, and that the performance over the original distances, as specified, could only be taken into consideration by the jury. In the meantime, owing to the anticipation that the suggestion, that the portion of the contest affected by the nail-strewn road should be eliminated, would be accepted, *L'Auto* had allowed it to go forth that certain cars were thereby the winners, which, under the final decision of the A.C. de France, proved not to be the case. The competitors in question not unnaturally, therefore, published advertisements announcing themselves as the winners of the competition, statements which subsequently, of course, had to be modified. Under these circumstances the A.C. de France have now inflicted penalties upon the offending firms for having given publicity to unauthorised and incorrect results. These take the following form:—Messrs. Lacoste and Battman, 1,000 francs fine and six months' suspension from competitions; the Vulpes firm and Messrs. De Dion-Bouton, 100 francs fine each.

Hydra Cup for Voiturettes.

After announcing details in regard to the rules to govern this competition, as is generally the custom on the Continent, a number of modifications are published in another set of "final" rules. It is now announced that the competition for the Hydra Cup is open to 4-wheeled voiturettes or small cars of a maximum catalogue price of 3,900 francs, complete with carriage body and ready for the road. The weight, with carriage body complete, is now announced to be a *minimum* of 350 kilogs., *instead of a maximum.* The distance is to be 1,000 kiloms. spread over three days, and the contest is to take place annually, the winning firm to hold the Cup and its privileges for one year. In 1906 the date chosen is June 8, 9, and 10. In addition to the Cup, the winner will receive 5 francs per day (in the event of the car being fitted with a Hydra ignition system, 10 francs per day) so long as the holders of the Cup are not beaten. The entrance fee is 100 francs per vehicle, of which 50 francs will be returned to starters. A maximum of three vehicles to each manufacturer is allowed, and the whole contest will be officially timed. During the two nights' rest cars will be strictly "parked," and no repairs or adjustments will be allowed, except in running time. The actual course has not yet been fixed. A special Cup for the best performance of any "team" of cars is also offered.

Bombay-Mahableshwar Reliability Trial.

A cablegram from India states that three cars have tied, for the best performances in this trial over 500 miles, for the Mysore Cup. These are a De Dietrich, a Richard-Brasier, and a Fiat. Under arrangement, it is also stated that each of the entrants will be the custodians of the Cup for three months. We await details of this event by mail.

⊛ ⊛ ⊛ ⊛

Through India by Car.

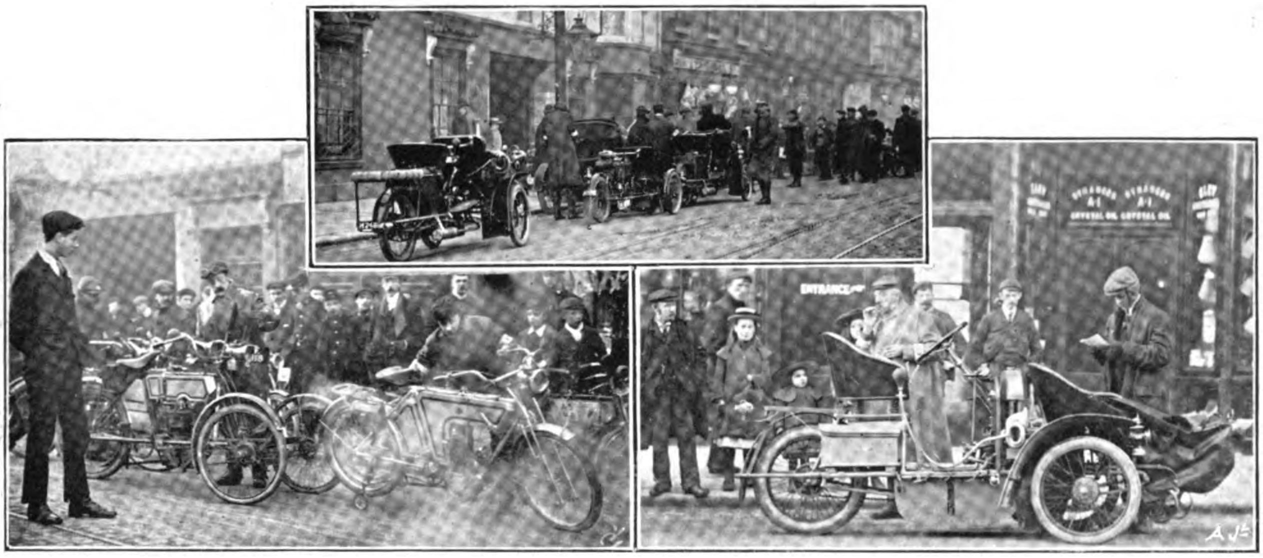
Mr. C. J. Glidden, to whose start on his tour through India and the Far East in the trusty Napier, which has already carried him nearly 30,000 miles, we referred to shortly before Christmas, has just cabled that he has added another 4,405 miles to his record. After landing at Bombay and driving northwards to the Khyber Pass, he drove right across Northern India by the Grand Trunk Road to Calcutta. As previously mentioned by us, Mr. Glidden intends extending his tour through Burma, Ceylon, Siam and Japan.

An Author's Name Omitted.

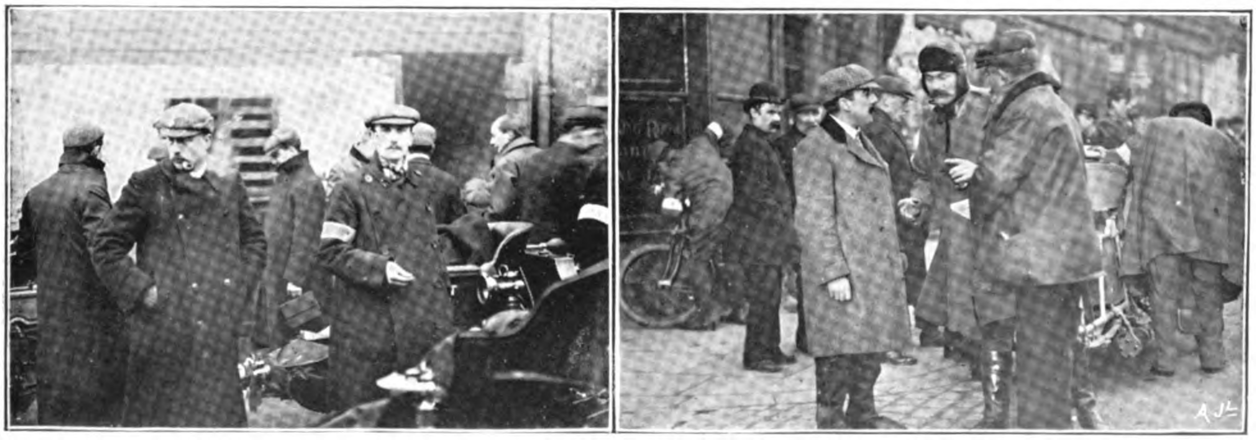
In our American contemporary *The Motor*, a serial article appears on "The Magneto," by Alex. Schwalbach. This is one of the many cases in America—and we are sorry to say in Germany also—in which, judging by the annexation of original matter and drawings, the name of The Automotor Journal should be included as either "part" or "sole" author.

MOTOR CYCLING.

AUTO-CYCLE CLUB 100 MILES TRIAL.—Inside the Chequers Inn, Uxbridge. Final preparations before the start.



AUTO-CYCLE CLUB 100 MILES TRIAL.—Outside the Chequers Inn. The competitors waiting to be sent off. Final adjustments and preparations.



AUTO-CYCLE CLUB 100 MILES TRIAL.—Before the start. Left picture: H. Fear, who entered a 4½-h.p. Stevens-Ashford tricar, and W. Pratt, who drove the machine in the trial. Right photograph: Messrs. Ashford and Smith. A knotty point.

Quarterly Trials (Auto Cycle Club).

SATURDAY last was the occasion of the first Quarterly Trial held by the Auto Cycle Club. These trials are open to any form of motor cycle, and on this occasion the entry list numbered twenty-one. Of these eleven were bicycles, the remainder being passenger machines. A start was made at the Chequers Hotel, at Uxbridge, at 9 a.m., there being only one absentee. From Uxbridge the route was to Banbury, where competitors were allowed to take in petrol and water—lubricating oil was on no account to be replenished throughout the journey—and from Banbury the machines had to be driven back again to Uxbridge, thus covering a distance of 125 miles. During the run, times were taken up Dashwood Hill, but these are not published on account of the Club rules. The following is a *resumé* of the results :—

No.	Entrant.	Machine.	Dash-wood Hill.	Remarks (see foot-notes).
		Bicycles.		
1	G. Hulbert	3-h.p. Triumph ...	—	D
2	H. G. Cove	3½-h.p.. F.N. (4-cyl.)	—	T
3	Quadrant Cycle Co.	3½-h.p. Quadrant ...	2nd	NS
4	,, ,,	,, ,,	—	D, I
5	W. Hayes	3⅜-h.p. Rex ...	—	D
6	Magneto M.M.C. ...	4-h.p. C.I.E. ...	4th	T, NS
7	,, ,,	,, ,,	—	D
8	G.B. Motor Co. ...	5½-h.p. G.B. ...	1st	NS
9	G. H. Wait	3¼-h.p. Clyde ...	Did not start.	
10	Werner Motors ...	4-h.p. Werner ...	3rd	NS
11	W. Hayes	3⅜-h.p. Rex ...	—	D
		Tri-Cars.		
12	Singer and Co. ...	6-h.p. Swift ...	6th	S, P
13	W. B. Barnes ...	6-h.p. Invicta ...	7th	V
14	Magneto M.M.C. ...	6-h.p. Barnes ...	—	C
15	Riley Cycle Co. ...	9-h.p. Riley ...	1st	R
16	M. Stewart	10-h.p. Lagonda ..	2nd	E^1
17	Werner Motors ...	5-h.p. Werner ...	—	B
18	Lagonda Motor Co.	10-h.p. Lagonda ...	3rd	T, I
19	E. E. L. Baker ...	10-h.p. Lagonda ...	4th	T, NS
20	H. Fear	4½-h.p. Ashford ...	—	C, Ch
21	G. W. Manning ..	10-h.p. Lagonda ...	5th	E^2

NOTE.—B = Belt trouble. C = Carburettor trouble. Ch = Chain broke. D = Stopped on Dashwood Hill. E^1 = Engine gudgeon-pin broke. E^2 = Engine piston seized. I = Ignition trouble. P = Short of petrol. R = Broke radiator in collision. S = Removed non-skid. T = Tyre trouble. V = Valve trouble. NS = Non-stop run.

Those competitors who are noted as having made non-stop runs will receive certificates, subject to the report being confirmed by the judges. Tyre troubles were not, except in the case of No. 2, allowed to interfere with otherwise non-stop runs.

Auto-Cycle Club—Annual Meeting.

THE date fixed for this meeting is March 14th, at 7 p.m.

The Annual Dinner.

THE third annual dinner of the Auto-Cycle Club, held on Wednesday of last week at the Criterion, must be voted the most successful of any social function hitherto held by the Club. A very large number of members and guests were present to support Mr. Robert Todd, in the chair, amongst these being Earl Russell, Col. H. C. L. Holden, Sir Martin Conway, Messrs. E. A. Lamb, Julian Orde, A. J. Wilson, R. Johnson, Lyons Sampson, H. W. Staner, E. R. Shipton, Stanley Spooner, C. A. Smith, J. C. Percy, W. Rees Jeffreys, G. F. Sharp, Wilbur Gunn, Walter Groves, F. W. Fowler, Dixon F. Straight (secretary), &c.

A very enjoyable function during the evening was the presentation of the medals and prizes to the successful competitors in connection with Club events during 1905, the list including the three Challenge Cups which were disputed at the Crystal Palace Annual Race Meeting in September. Much enthusiasm reigned amongst the guests, an excellent spirit of camaraderie being a feature of the evening's entertainment.

Following the loyal toasts, in proposing the toast of the evening, "The Auto-Cycle Club," Earl Russell said that no one in the motor cycle world could afford to remain outside the fold of the club. He pointed out that it was a matter for much satisfaction that the British team in the International Cup Race last year was the only one which finished the race. During his remarks he urged very strongly upon members to use every opportunity of suppressing the misuse of the motor horn by the "push bicyclist."

Colonel Holden, who responded to the toast, drew attention to the excellent programme for 1906 which had already been arranged, including the Club's open hill climb, penalty run, Land's End to John o' Groat's trial, the International Cup Race, a six days' trial, a consumption trial, the passenger motor trials, and the annual race meeting. The latter, Colonel Holden pointed out, was the only meeting in the United Kingdom at which only mechanically-driven machines were allowed to compete. As indicating the feeling of respect and the popularity which the British team earned on the Continent at the International Cup Race last year, Colonel Holden read a communication which had been received from the Marquis of St. Mars, to whom the Club have presented a gold medal in recognition of the services he rendered the British contingent at the International Race, at Dourdan, in June last. The Marquis's letter was as follows :—

"I wish first to express my great regret that I am unable to be present to-night at the anniversary dinner, to which you have so kindly asked me. It would have been a great pleasure to thank you all personally for the beautiful memento you have given me of my very pleasant trip in France with the English competitors, and though I feel it almost undeserved I shall always prize the medal as a token of the goodwill and friendship of the members of the Club.

"It seems incomprehensible to me that an industrial and commercial nation like England should handicap an industry which already

AUTO-CYCLE CLUB 100 MILES TRIAL.—Some of the entrants at Uxbridge. In the picture on the left are Messrs. W. Gunn, E. L. Baker, G. W. Manning, H. Fear and Fry; in our other photograph, Messrs. G. Hulbert and O. C. Godfrey are prominent figures.

employs so many of the working class, and has unlimited capacity for the employment of so many more. It is unnecessary for me to dwell upon the difficulties which English competitors experience against their foreign antagonists—they are too obvious and too well known—but let me say we have seen the success of a well-built British car in Continental races, and I need not emphasise the fact of the influence it has had on the public mind, nor the very substantial pecuniary result it has brought the Company. Therefore, with such a brilliant example before us, with so much to gain, it seems superfluous to beg the motor cycle industry to do their best to help the Club in the forthcoming races.

"The same success that has attended the British car *must* attend the British-built motor cycle. Though great difficulties may be in the way they must be overcome.

"Pray remember that whatever criticisms have been passed on the English team in the recent International Race, it was the only one running complete at the finish. Let me add that the sporting way the Englishmen conducted themselves, combined with their strict observation of all rules, won for them my sincere admiration, and not only mine, but the admiration of all the clubs present."

Colonel Holden then referred in complimentary terms to the work done by Mr. O'Gorman in smoothing over several difficulties which had existed with the French Club, and he concluded by endorsing the advice of Earl Russell in regard to the stopping of the abuse by cyclists of the motor horn.

Mr. Wilbur Gunn, who responded on behalf of the affiliated clubs, said he looked to the A.C.C. to watch the united interests of auto-cyclists in the forthcoming re-consideration of the motoring laws. He hoped the whole body of motor cyclists would work in harmony to one end, viz., the general good. Through the Auto-Cycle Club, he thought the whole of the riders were brought together in one catholic body, which upon emergency was able to present a strong front to any enemy of the sport and pastime. On behalf of the trade he congratulated the Club upon the splendid way in which they had carried out all trials, and the fairness and diplomacy with which all doubtful points and disputes had been dealt with by them.

Mr. H. W. Staner, in whose hands was the toast of "The Pastime and Sport of Auto-Cycling," thought that in the face of oft-repeated assertions that motor cycling was dead, the gathering of the Club that evening demonstrated that the sport was in a very healthy condition. He looked in the future for a three or four-cylinder motor cycle on a spring frame to establish the pastime upon a firm basis. In racing against foreign manufacturers, Britishers, he thought, should fight them with their own weapons, irrespective of what, as sportsmen, we might think. Nothing but horse-power could secure big international races, and he would rather advocate one efficient representative machine for Great Britain than several inefficient machines. Finances to this end were necessary, and he urged both makers and sportsmen to come forward with generous funds to support the British position in the International motor cycle world. It was essential for the industry that we should win one of the big Continental races, and thereby secure for home manufacturers the support of the British buyer.

Sir Martin Conway responded to the toast, and after the "Visitors" had received due recognition, very great cordiality marked the usually formal toast accorded to the chairman.

CLUBS AND ASSOCIATIONS.

A.C.G.B.I. Examinations for Driving and Mechanical Proficiency Certificates.

AN examination for the above was held last week. The number of entries was by far the largest on record, and it is hoped to announce the results within the next few days.

The next examination for London is to be held on February 21st at 119, Piccadilly, W., and will be continued on the following days if found necessary.

A large number of candidates are expected to attend the provincial examinations, which take place during this month and next, particulars of which are below:—

January 30th, Liverpool (Exchange Hotel); 31st, Blackburn, (White Bull Hotel); February 1st, Leeds (Gt. Northern Hotel); 2nd, Newcastle (County Hotel); 3rd, Darlington (N.E. Hotel).

Scotland.—February 5th, Glasgow; 6th, Edinburgh; 7th, Dundee; 8th, Aberdeen.

Hertfordshire County A.C.

THIS club has had a large accession to its membership through the decision of the West Herts Motor Club to wind up and join the County Club, in order to make one strong automobile body for the county. At a committee meeting of the County Club, held on January 18th, the following members of the late West Herts Club were elected to membership:—Messrs. J. T. Gardner, T. Williams, J. H. Evans, G. H. Gray, J. S. Harwood, A. J. Salmon, Matthew Arnold, E. H. Arnold, H. S. Adey, Basil Crump, M. A. Colebrooke, R. S. Cooper, D. Doyle, J. H. Evans, R. Ellis, W. S. Edmunds, Dr. Ellerton, Messrs. P. Fisher, R. M. Finlay, P. Gowlett, J. Harwood, A. B. Horton, Drs. J. S. Hudson and A. L. Reid, Mr. G. H. Hedge, Rev. A. J. McKinney, Mrs. Monro, Mr. Chas. McWhirter, Mrs. McWhirter, Messrs. W. S. Wilson and R. Wheelwright.

Wolverhampton A.C.

MEMBERS of the Club foregathered at the Star and Garter Hotel, Wolverhampton, on Friday of last week, for the occasion of the fourth annual dinner. A goodly company of automobilists with their guests assembled under the chairmanship of Mr. Edward Lisle, the president, including Captain Burnett (Chief Constable), Messrs. T. Cureton, T. T. Mills, F. Bishop, A. Scott, J. O. Evans, W. H. Evans, G. W. Evans, J. W. Davis, P. Percival, W. Rees Jeffreys, J. Lisle, T. Lisle, T. G. Gatis, I. H. Baxter, Beddows, W. H. Edwards, Boswell, Tomlins, E. A. B. Woodward, Dr. Pratt, Dr. Grout, and Mr. S. R. Rhodes (secretary).

A great compliment was paid the members of the Club by the toast of "Success to Automobilism" being submitted by Captain Burnett, the Chief Constable. Mr. Rees Jeffreys, in responding, drew attention to this fact, saying it was a satisfactory omen that in Wolverhampton a chief constable proposed the toast Captain Burnett had done; in many towns it would be impossible to induce a chief constable to perform such a service. One of the things automobilists had to do was to suppress the reckless and inconsiderate motorist. He was not to be stopped by police traps, but by clubs, such as Wolverhampton, working in harmony and co-operation with the police authorities.

⊛ ⊛ ⊛ ⊛

LEGAL PUZZLES.

An Acrobatic Case.

IN another case, which came before Mr. Justice Bigham and a special jury last week, Mr. Lloyd, the owner of a private motor car, which had a collision with a van belonging to Messrs. Bean & Co., sued the latter for damages to his car. The smash appeared to have been a very bad one, and created so much excitement that a whole crowd emerged from the "Stag and Hounds" on the Staines Road, where the accident occurred. On this statement being made, one of the counsel engaged sarcastically inquired whether the policeman and customary children, who are kept in attendance for such occasions, also emerged. A photographer gave evidence that he was so much frightened by the collision that he fell off his bicycle on seeing the motor car turned over and the four occupants fired into the air. Finally the jury stopped the case, and gave a verdict for the defendants on claim and counter-claim, the result being that the proprietors of the van were awarded £10 5*s.* 6*d.* compensation.

Heavy Damages.

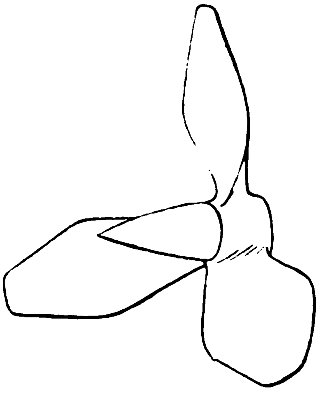
A CASE was heard at the Court of King's Bench on Thursday of last week, in which Mrs. Norton claimed damages for the death of her husband, Mr. W. H. Norton, a civil servant in the receipt of £400 a year, who was killed by being run over while cycling at Anerley, by the motor car of Mr. F. W. Baily, of the Crystal Palace. After a protracted hearing, in which the evidence tendered was of a somewhat conflicting character, and in spite of what appeared to be very clear evidence that the manner in which the cyclist rode contributed to the accident, the jury found a verdict for the plaintiff, and assessed damages to be accorded to her at the large sum of £1,500. At the Coroner's inquest upon Mr. Norton, it will be remembered, Mr. Baily was entirely exonerated.

MOTOR BOATING.

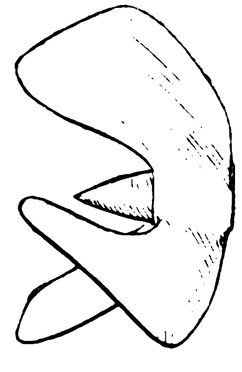
A 25-ft. Yacht Motor Tender, constructed by Messrs. Brooke and Co. for the Hon. Walter Guinness' Yacht. She is fitted with an 18-h.p. 4-cylinder Brooke motor, and gives a speed of ten miles an hour.

Propellers.

ON Thursday evening, the 18th inst., Mr. D. Ramsay Smith read a paper on the subject of propellers before the British Motor Boat Club. The author gave an account of the historical development of the propeller, and dealt in general terms with the theory of boat propulsion. Three-bladed propellers are, said Mr. Smith, used more often than others because they have been shown to be capable of transmitting the greatest amount of power under the most exacting conditions. Tramp steamers and other boats continually calling at jetties are generally fitted with four-bladed screws, however, because if one gets knocked off, the propeller is not thrown so much out of balance as it would otherwise be. Mr. Ramsay Smith illustrated his lecture by chalk drawings, and we reproduce two sketches of propellers made by his firm.



High-speed Propeller.—Constructed for the Putney Motor Company, Limited, to transmit 30-b.h.p. at 960 revs.



Towing Propeller for Thames Tug. Weight 17 cwt. Designed and fitted by D. Ramsay Smith and Co.

"Perle de la Mediterranee."

THE Cavaliere Vincenzo Florio, who has given such encouragement to automobilism in Italy, by creating the Florio Trophy last year, and who has for this year organised the Targo Florio for motor cars in Sicily, has sent us particulars of another important competition, this time for motor boats, entitled the "Perle de la Méditerranée," for which he is engaged in elaborating the arrangements, and has also offered a trophy. The scene of this event, which will comprise probably the longest distance for which motor boats have ever yet competed, viz., 842·660 kil., will also be Sicily, and will include the complete circumnavigation of that island, and will be carried out in six different stages. The race will start from Palermo, the first stage ending at Messina (222·24 kil.). From Messina, the second day's run will be to Catania (92·6 kil.), the next stage to Syracuse (55·6 kil.), the following stages being from Syracuse to Girgenti (222·24 kil.), Trapani (148·16 kil.), and back to Palermo (101·86 kil.). The Cavaliere points out that the course is an ideal one for motor boats, as it traverses three different seas, the Tierrenian, Ionian, and Mediterranean Seas, in which different kinds of weather and currents may be expected, while in addition to the harbours at which the different stages end, the indented character of the coast provides admirable protection in case sudden storms should arise.

There are two classes in the competition, viz.: (1) racers, (2) cruisers, each subdivided into three categories, viz.:—

	RACERS.	CRUISERS.
Cat. 1	Up to 8 metres.	Under 8 metres.
,, 2	,, 12 ,,	,, 12 ,,
,, 3	,, 18 ,,	,, 18 ,,

The trophy to be awarded to the winner, entitled the "Perle de la Méditerranée," consists of a large pearl mounted on a gold plate, and valued at about 8,000 francs, in addition to which some 50,000 francs will be distributed in various other prizes.

* * * *

A Real Guide to the Press.

WE have received the thirty-third annual issue of Willing's Press Guide, which presents all the admirable features of previous issues, and has been brought thoroughly up to date. The present "Willing's" is like the others, and in saying that we cannot praise its thoroughness and reliability more.

CORRESPONDENCE.

*** *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion, or containing queries.*

THE FLYING PROBLEM.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—If Mr. J. D. Roots would kindly give us an illustration of his flying machine, it will, I am sure, be of much interest to some of your readers. Unlike Mr. Roots, I pin my faith to the aeroplane, and am unable at present to see how flight can be a practical success without its use, for it is on this principle that birds fly, and the finest example is the albatross. Even those birds who flap their wings rapidly are in reality taking a quick succession of aeroplane glides. If birds were clever enough, and provided they had sufficiently light and powerful motors, they could save themselves a good deal of exertion by keeping their wings outstretched, allowing themselves to be mechanically propelled. Then again, have not the Wright Brothers proved beyond doubt, with their rough, crude machine, that the future of the aeroplane system is enormous?

To those who have watched the albatross, some of which measure 14 feet from tip to tip of wing, gliding on the air with no perceptible movement of the wings, and flying in this way in a straight horizontal line against the wind, it seems that nothing else but success should crown the efforts of exhaustive experiments.

I have made numerous aeroplanes since 1894, and have had some very interesting and successful steering glides with three-foot models on the dart principle fitted with vertical and horizontal rudders, some of the models having propellers driven by elastic. But recently I have been experimenting with models of the Wright Brothers' machine, having obtained excellent results and some very instructive data. I would be interested to know if anyone else has been experimenting with Wright Brothers' aeroplanes in England.

At present I am working on a combination of the Wrights' and my own type, and hope to have some very good results. If immediate steps are taken, I consider motor-driven aeroplanes should be gliding over England by the middle of this summer.

I would be pleased to hear from anyone interested in this subject, and also to send, at an early date, to THE AUTOMOTOR JOURNAL a photograph of one of my 40-inch Wright aeroplanes.

Yours faithfully,

A. V. ROE.

23, Brunswick Terrace,
Brighton.

4 CYLINDERS *v.* 6 CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I notice my friend, Capt. Deasy, says that, in common with others, he is interested in the merits of 6-cylinder cars. I am naturally pleased to hear it, and, I hope, prior to his starting his British Company, he will have learned about the advantages of the 6-cylinder and that he will assist in taking the trade from makers of foreign cars, who, from manufacturing reasons, have not yet been able to adopt the 6-cylinder principle, although knowing that it is best and adopting it in the latest cars they are building for competition.

In response to his wishes, it will give me great pleasure to match a 6-cylinder Napier car against a foreign 4-cylinder for a 100 miles race, as suggested by Capt. Deasy, of equal capacity, and will cross to the Continent with Capt. Deasy to decide it.

My 6-cylinder engine will have six cylinders of 6¼-in. bore each, 5-in. stroke. Capt. Deasy could have his four cylinders of not less than equal total capacity, or even greater if he likes. I have no objection to his having four cylinders as large as he likes, providing, of course, that he keeps to the official rules and regulations that the weight of the car does not exceed 1,000 kilogs. in running order on the road.

If, at the same time, he would like to test other advantages, such as silence of the respective cars, wear and tear of machinery, wear and tear of tyres, petrol consumption, and, in fact, any other competitive points, hill-climbing on top speed, slow running on top speed, even running on top speed, and running, say, 500 miles without changing speed at all, always remaining on the top, I should be pleased to agree to all these points, as I feel that an official trial of this sort would ensure Capt. Deasy's factory turning out nothing but 6-cylinder cars and put another nail in the coffin of the foreign car, as there is no doubt it is always pleasing to the user of a motor car to think that the money he has spent on it is helping to keep British workmen rather than foreign ones.

Yours truly,

S. F. EDGE.

January 20th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Captain H. H. P. Deasy, in THE AUTOMOTOR JOURNAL, suggests that the respective merits of 6-cylinder and 4-cylinder cars should be arrived at by a proper trial between the two in the form of a match over 100 miles of give-and-take country, the engines of the cars having equal capacity. It would be interesting if Captain Deasy would state whether his proposal is that the match should be a race pure and simple. If so, apparently he thinks that the question as to which is the better car can be settled by a test of speed and reliability over a distance of 100 miles. I have found that everyday people who are purchasing cars are much more anxious as to the qualities of silence, smoothness, shocklessness, absence of smell, absence of smoke, and luxury of suspension than they are on the question of whether a car will go a mile or two an hour faster than another car. The idea that the chief merit of a car lies in the extent to which it can break the laws of the country is, I think, wrong.

If Captain Deasy's match includes a trial of the two cars on the more important points I have mentioned, I believe that C. S. Rolls and Co. would gladly provide a 6-cylinder car for the purpose of the match, and I would suggest that the jury should consist of three ladies and three gentlemen who have been in the habit of driving in carriages drawn by horses, and who are not wedded to any particular form of motor traction. The two halves of the jury would change cars at the half-distance. I believe that the 6-cylinder Rolls-Royce has a cylinder capacity of 377·4 cub. in., and the 30–40 Martini 340·12 cub. in. Possibly, if the question of speed is, as I suggest, to be left out of the match, Captain Deasy would consider that the capacity of the two engines is near enough for a test of the other important qualities of the respective cars.

Yours faithfully,

Jan. 20th. CLAUDE JOHNSON.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Why so much discussion on the merits of the two engines? One thing only will determine which will be the car of the future —the future itself.

As a purchaser in a position to afford it, I should not hesitate for a moment, but fix at once on a 6-cylinder. As a manufacturer I am catering for both the client who wants a 4-cylinder car and one who wants a 6-cylinder car, but I have a lingering notion that in twelve months' time we shall have only one model "Brooke" car, and that a 6-cylinder.

Only a short time back I was driving a 6-cylinder car with one cylinder missing, but it was hardly noticeable. On the same day I was driving a 4-cylinder car with one cylinder missing, and the difference!

Yours faithfully,

January 22nd. MAWDSLEY BROOKE.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I read in your issue of January 13th some measurements given by Mr. Edge, I believe, to your correspondent, Mr. Colebrook. Mr. Edge's letter appeared to answer every point which Mr. Colebrook asked, and clearly showed how well distributed the weight of the 6-cylinder was.

I was somewhat surprised, therefore, to see in your current issue that Mr. Colebrook is not satisfied with the answers he received, and for some unknown reason wishes to suggest that the answers are not what he wished, although they appeared to be quite definite answers to his questions.

The matter, however, has interested me so much that I have taken the trouble to find out the truth.

The first point on which I must join issue with your correspondent is where he says that he has taken the dimensions of a 40-h.p. Mercedes car, in which he says that the design is absolutely up to date. He must surely be perfectly well aware, firstly, that there is no such thing as an up-to-date 40-h.p. Mercedes, as they do not make this model for 1906 type. Secondly, he must know quite well that the Mercedes designers in their more recent cars have very properly put their back wheels further back than they used to have them in the past, and thus enormously increase the weight on the front wheels. Being good designers, they appreciate that a very large amount of the weight of the machinery of the chassis ought to be carried on the front wheels, as with the present heavy bodies and large seating capacity, the back wheels have as much weight as they can carry and need for driving purposes without engine weight.

His next statement, that a 6-cylinder engine has the whole weight placed too far forward over the front wheels, is wrong. Let us be charitable, and hope ignorantly wrong, and unless your correspondent will state what make of 6-cylinder he has seen built in this way, I fear I must question the truth of the statement. I have taken the trouble to measure a 40-h.p. 6-cylinder Napier, and I find that the back of the front axle, instead of being behind any portion of the Napier cylinders, as your correspondent would suggest, is *actually* one inch in front of them.

As to the question of the bonnet being carried over the front axle unduly increasing the weight on the same—certainly. As one with some technical knowledge, I cannot believe that the weight of a motor car bonnet (I have weighed the one that fits over the 40-h.p. engine of the same car, and find that it weighs 18½ lbs.) could have any serious effect that was good or bad on the steering of a car. It would be interesting to see what sort of faulty steering the car has that your correspondent refers to that so strangely has its steering adversely interfered with by the small portion of the meagre weight of the bonnet over the front axle.

Yours faithfully,

South Ealing, W. G. SMITH.

CLAIMS BY THE PUBLIC—INSURANCE OF MOTOR CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—If you will allow me to recite the following particulars they may prove to be of interest to your readers.

On the 9th day of October, 1904, one of our policyholders, a Mr. Baily, riding on his car, collided with a cyclist—a Mr. Norton—and unfortunately killed him.

The police investigated the particulars and decided not to prosecute.

The coroner's jury exonerated Mr. Baily from any blame.

Some little while after a firm of solicitors wrote claiming compensation on behalf of the widow, but upon looking into the facts threw the case up as a hopeless one to fight.

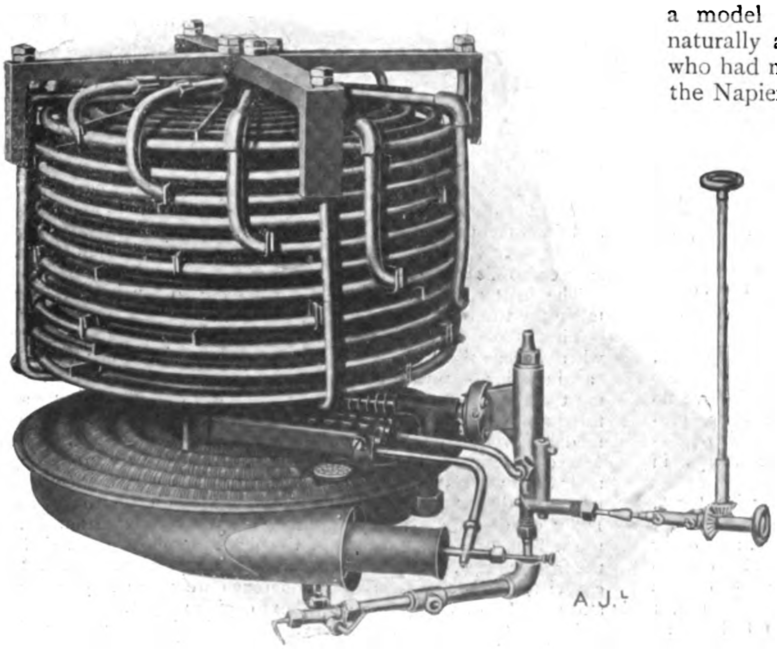
Nearly a year passed when another firm of solicitors began proceedings on behalf of Mrs. Norton, and last week a special jury, in Mr. Bigham's Court (King's Bench), in spite of an apparently very clear case, awarded Mrs. Norton and her son and daughter the sum of £1,500, which with costs means practically an award of £2,000.

Fortunately for Mr. Baily he was insured with us for £1,000, so that he only has to bear himself a loss of £1,000 instead of £2,000. This case, however, shows very clearly the value of sympathy in a third party action, especially when a motor car happens to be involved.

Yours truly,

FREDERICK THORESBY,
General Manager, Car and General Insurance Corporation, Limited.

1, Queen Victoria Street, E.C.
January 22nd, 1906.



On the present 18-h.p. White Steam Cars, the burner differs from those hitherto employed on this well-known make of vehicle, the chief change being that the whole of the air now enters around the fuel-jet; the burner is therefore closed in beneath. Our illustration shows the new steam generator with the burner in place beneath it; the earlier form of burner—as used on the 10-h.p. and 15-h.p. models—was similarly illustrated by us on July 25th, 1903. Full particulars of the latest White Steam Cars were given in our issue of September 30th last.

Crystal Palace Exhibition.

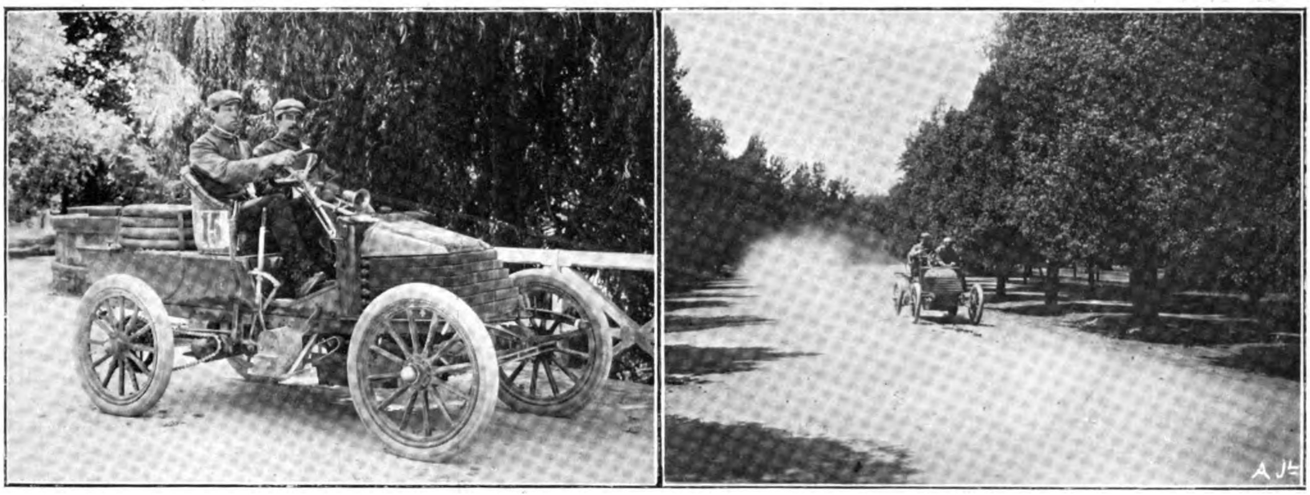
THE Motor Show opening on Friday of this week, closes on February 3rd next. The stand of THE AUTOMOTOR JOURNAL will be in its old place in the centre of the building by the High Level Station entrance—its number is 35. Several novelties, it is announced, will be staged, especially in the motor boat section, of which the organisers are making a special feature. An Itala car, constructed for Queen Margherita of Italy, is an attractive exhibit promised, whilst the Fabry Company will be showing a 100-h.p. racer, and a 200-h.p. 8-cylinder Darracq racer will be on view.

Birmingham Motor Show.

THE second annual Exhibition of motor cars was opened on the 19th inst. by the Lord Mayor at the Bingley Hall, and closes to-day (Saturday). After the Olympia and Paris Shows, no new chassis could be expected to make its *début* at Birmingham, and with the exception of the new 4-cylinder Quadrant car, which is fitted with the Lloyd change-speed-gear—illustrated and described in our issue of November 4th last year—there is practically nothing novel. No doubt a number of local residents, however, were unable to see the Olympia Show, and to these the representative nature of their own Exhibition must have been very gratifying. Such well-known firms as Argyll, Clement, Clement-Talbot, Daimler, Delaunay-Belleville, Humber, Mercedes, Napier, Panhard, and Renault were well represented, either direct or by their agents. Most of the up-to-date cars are of course represented locally, but among those who came up from London especially for the event may be mentioned Messrs. S. F. Edge and J. E. Hutton, both of whom had fine exhibits of the special cars in which they are interested. On the Napier stand was a model of one of the latest 6-cylinder cars, which naturally attracted considerable attention among those who had not already seen the most recent product of the Napier works.

Motor Pupils.

MOTOR car schools which do not teach the aspiring pupil automobilism, have been responsible for a good deal, but it is satisfactory to find that the Forman Motor Company, of Coventry, who took a pupil with a premium of £20, and were alleged, instead of making him an expert motor engineer and driver, to have converted him into a burglar instead, are absolved from the heinous charge. An action was brought by the parents of the young man (who, it now appears, had a "past") for the return of the £20, and it was alleged that the defendant company taught him so little, and made things generally so unpleasant for him, that he came to prefer the profession of burgling to that of chauffeuring. The evidence, however, showed that he learned nothing because he wished to learn nothing, and that the only engineering job he actually executed when on the works, was the manufacture of a tool for opening doors, locks, and safes, popularly known as a "jemmy." Under the circumstances it is not surprising to learn that the jury gave a verdict for the defendant company.



MELBOURNE-SYDNEY RELIABILITY TRIAL.—We have received the above photographs from the Wolseley Motor Car Company, and they depict one of the Wolseley cars (No. 15) which took part in the test. In the contest this car was particularly unlucky, having to cross an exceptionally rough country, owing to the road being blocked near a bridge by another car which had met with an accident. In endeavouring to pass ovei the loose sand and big stones, the car rolled aside and struck the front wheel against a boulder, bending the axle badly. Yass, about 11 miles distant, was with considerable difficulty reached under the conditions, but in spite of this, when the axle had been straightened out, the car steered and travelled splendidly, averaging about 28 miles an hour through the hilly country into Goulburn. Unfortunately, the mishap caused a loss of 3 hours 12 minutes, equal to 192 points.

Popularity of the "Yellow Cover."

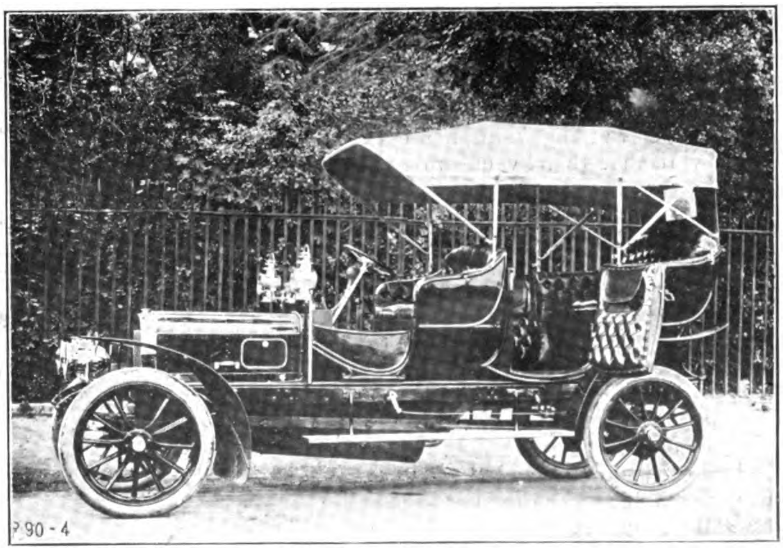
We hear on good authority that at a Service fancy dress ball at Chatham last week, one of the most successful costumes represented The Automotor Journal (yellow cover). We are pleased to hear of this as emphasising the widespread popularity of our Journal. We need hardly say this costume was selected without the slightest suggestion from anyone connected either directly or indirectly with our editorial or commercial staff.

Motor Car in Romance.

The motor car has played quite a romantic part recently. We do not so much refer to the unsuccessful attempt made by a Parisian *viveur* to abduct a variety "star" in a motor car filled with flowers, as to the romantic affair which has set most of Europe talking, the elopement of Count Francis Erasmus, the heir to the territorial county of Erbach in the Odenwald, which has recently been announced. The young Count insisted on marrying a peasant girl who resided in the neighbourhood of his ancestral castle. There was the customary family quarrel, and various other quarrels, and, finally, one morning, the heir of a title and estates—which have been in his family since the days of Charlemagne—walked out of the castle, which is one of the most splendid and widely celebrated in Germany, met the object of his affections at some distance in the forest, and whirled her off to France in a motor car. The pair finally found their way to London, where they were married. The automobile was requisitioned, as the young Count anticipated forcible opposition on the part of his family. It is one of those strange coincidences which history sometimes provides that the origin of the Erbach family was from a not dissimilar *mésalliance*, the Counts of Erbach tracing descent from the union of Charles the Great's daughter Emma with his celebrated secretary, Eginhardt.

Back to the Road.

The establishment of road motor 'bus or motor coach service for which the Vanguard people are primarily to be thanked, is leading to further developments in the same direction, and a number of vehicles styled motor coaches are, we understand, under construction and will be placed in service shortly by a company entitled the London and South Coast Motor Service, Limited. The main object will be to familiarise passengers with the beauties of the scenery in the southern counties while at the same time charging very moderate fares.



DESIGN IN CARS.—A well-designed 20-h.p. Thornycroft Car, belonging to Mr. A. M. S. Methuen, which during the election for the Guildford division of Surrey did yeoman's service in the automobile cause, conveying in one case eleven voters at once to the poll.

One of the new White model cars, showing the latest style of American body. An interesting point in the photograph is the crouching beast which is seen on the rocks, and is carved out of stone, this forming a special attraction to many tourists who visit the district.

Objections to the Motor Road.

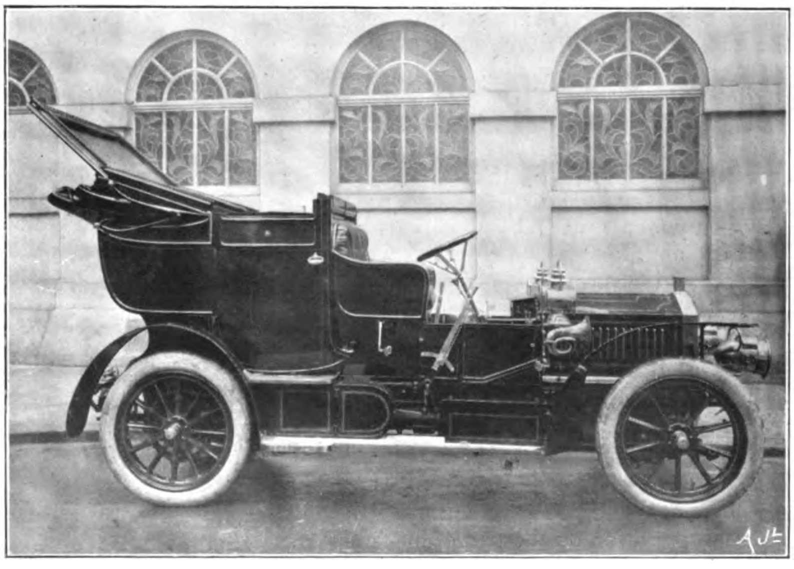
We are not sorry to find that the proposed Bill for permitting the construction of a "motor road" from London to Brighton, or more accurately speaking, from Croydon to Patcham, is commencing to evoke public opposition. Already an objection has been raised in regard to the title, on the ground that it is not proposed to really construct the road from London to Brighton, but from Croydon to the village mentioned above, and that the title of the Bill is therefore a misnomer. Other grounds of opposition are that the scheme, if sanctioned, would confer large and important powers hitherto usually conferred by Parliament only on railway companies (a point with which we dealt editorially last week), while, in addition, the scheme, as originally proposed, suggested that the road would be confined entirely to automobiles and not to vehicles propelled by motive power obtained from some outside source (this, we presume, refers to the suggestions that have been put forward for providing electric power from trolley wires for electrical vehicles).

The Hon. Arthur Stanley, M.P., Chairman of the A.C.G.B.I.

We beg to tender our heartiest congratulations to the Hon. Arthur Stanley, the Chairman of the Club and Motor Union, on his return to Parliament for the Ormskirk Division of Lancashire. The presence of the chairman of the two bodies in the House of Commons during what will probably be a fateful session for automobilism, is of the highest importance in the interest and welfare of the movement.

Edinburgh Exhibition.

This week-end the annual Motor Show at the Scottish capital opened for the usual week's exhibition of the leading types of cars in the country. Naturally such Scottish firms as the Argyll and the Arrol-Johnston are strongly represented, whilst all the well-known makes, such as Napiers, Daimlers, Wolseleys, Iris, Rolls-Royce, Panhards, Mercedes, De Dion, Fiat, Crossley, De Dietrich, Swift, Ariel, Clement, &c., are in evidence either directly or through their agents. It is yearly becoming more popular for a number of sportsmen to drive cars up by road, and amongst these this time will be found Mr. Charles Jarrott (22–28-h.p. Crossley), Mr. J. W. Stocks (24-h.p. De Dion), Mr. A. E. Perman (Iris), Messrs. Victor Miller and D'Arcy Baker (24–40-h.p. Fiat Omnibus). Mr. Jarrott and Mr. Stocks are running "in harness" in friendly rivalry, thereby ensuring an enjoyable sporting run. These two old "cracks" were to start together from the General Post Office at 9 p.m. on Friday of this week *en route* for the General Post Office, Edinburgh. The intention is to run straight through, keeping to a time-table throughout, allowing for the completion of the journey in 20 hours—just up to the legal limit. Both will, at the same time, endeavour to make engine non-stop runs. Mr. A. E. Perman started earlier in the week upon his little trip, he combining business with pleasure by calling at Leicester and Darlington *en route*, where he had arranged for special demonstrations with his Iris car. Mr. Perman was due at Stand 94–95 at the Edinburgh Show to-night (Saturday).



In our photograph is seen the new 18-h.p. Napier Landaulette which has just been built for the Hon. J. W. Lowther, the Speaker of the late Parliament.

CLÉMENT CARS
HEAD THE POLL
THE CLÉMENT MOTOR Cº Lᵀᴰ 3. Leicester Sᵀ London W.C.

A well-designed up-to-date "election" poster just issued by the Clement Motor Company.

COMMERCIAL POINTS.

What's in a Name?

MESSRS. CHARLES JARROTT AND LETTS, it is generally understood in the automobile world, are very extensive dealers in motor cars. Their name, however, appears to be fairly familiar outside the automobile industry, as we learn that quite a number of people have written them lately asking them to supply them with their diaries for 1906, against remittance. Probably this is accounted for by the rate at which most people now try to get through life, as the confusion probably arises by taking a glance at "Charles," the first name of the firm, skipping the centre, and noting only, in addition, the last name, and thereby assuming that they are the proprietors and vendors of "Charles Letts'" diaries.

AT the Berlin Automobile Exhibition in February, the Continental Caoutchouc and Gutta Percha Company, Hanover, have arranged to hold a tyre fitting competition, in which they will offer cash prizes to the value of £50 to those accomplishing the fastest times in fitting Continental motor tyres.

THE Birmingham Motor Car Company advise us that they are removing to more extensive premises at 208, Corporation Street, Birmingham, exactly opposite the Law Courts. They will then have very extensive show-rooms, and will have a specially equipped repair shop and garage available for all emergencies. They inform us that they will be in a position to repair at least thirty cars at one time and to garage more than that number, the ground floor alone covering an area of 9,000 square feet. The company are the Midland agents for the Argyll cars, the Delaunay-Belleville, and Sunbeams, spare parts of which makes are always kept in stock.

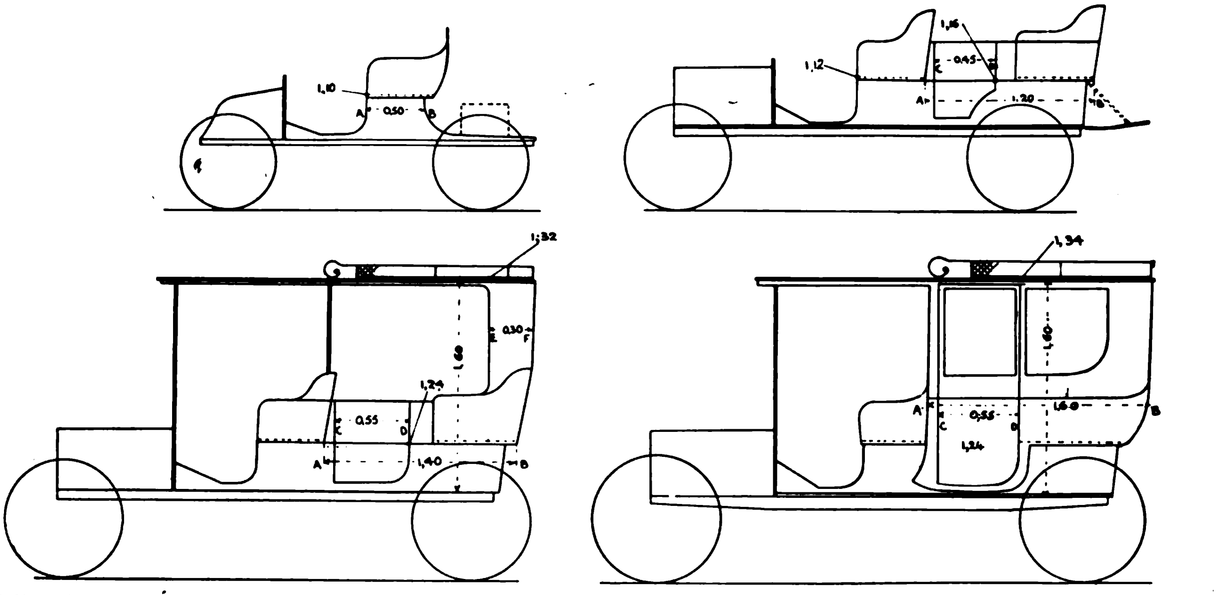
Mr. A. E. Perman on his Iris car, which he is driving to Edinburgh Exhibition.

A USEFUL desk blotter is to hand from the Shrewsbury and Challiner Tyre Company, Limited, of Ardwick Green, Manchester. It is specially convenient, as it is fitted with two flaps which close over when not in use, and thereby serve for the safe keeping of current papers in abeyance. The company will be pleased to forward one of these desk companions to any of our readers free upon receipt of name and address.

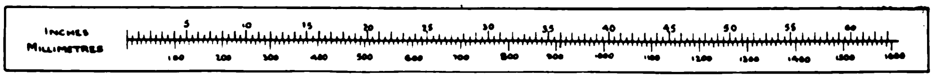
MAJOR RENTON, the Liberal candidate for Gainsborough, has selected a 4-cylinder National car, which, with the exception of the engine, will be of similar design to the 3-cylinder National which was Major Renton's first purchase.

THE British Automobile Commercial Syndicate, Limited, have been appointed the sole London selling agents for Clement Talbot cars manufactured in England.

INFORMATION comes from Calcutta that a proposal to provide two motor vans for the carriage of samples of tea from the sale tea warehouse at Garden Reach to the distributing centre in the city has been approved by the Port Commissioners, and an order has been placed for two 16-h.p. two-cylinder Albion motor delivery vans.



CIRCUIT EUROPÉEN.—Diagrammatic sketches indicating the sizes and types of carriage bodies, specified by the rules for each of the four classes. Certain of the dimensions indicate the width at those points, and all the seat measurements are taken at the top of the boot ("*parclose*," meaning the space beneath the seat); the width is measured from outside to outside, except in the case of the canopy, where the weathering (*les jets d'eau*) is not included. In all cases, the weight of the bodies (75, 200, 375, and 450 kilogs. minimum) is to include mudguards, steps, and the usual lamp brackets.



For the convenience of those wishing to convert metric figures of measurement into English feet and inches, we give this comparative scale, and believe that it will be found useful in connection with the above diagrams that refer to the Circuit Européen.

NEW COMPANIES REGISTERED.

Allsop Motor Syndicate (Limited).—Capital, £6,000 in £1 shares. Object, to acquire patents relating to petroleum engines, by agreement with R. O. Allsop.

Glasgow Motor Haulage Company (Limited). —Capital, £20,000 in £1 shares. (Scotch Co.)

Motor Drivers' Union (Limited).—Capital £1,000 in £1 shares. Object, to acquire the business carried on by Riski Medawar, at 47, Victoria Street, Westminster, as the Motor Drivers' Union.

Motor Lorries (Limited), 7, Thomas Street, York.—Capital, £10,000 in £1 shares. Object, to acquire the business carried on by J. E. Gibbs at Thomas Street, York, as John E. Gibbs.

N.A.G. Automobile Company of Great Britain and Ireland (1906) (Limited), 11, Gresham House, Old Broad Street, E.C.—Capital, £5,000 in £1 shares.

New Motor and General Rubber Company (Limited). —Capital, £1.500 in £1 shares. Object, to acquire from T. Warwick the business of rubber and general tyre manufacturing and repairing carried on at 61, High Street, Shaftesbury Avenue, W.C., as the Motor and General Tyre Company. First directors, T. Warwick, W. Turner, and J. Brewer.

Reliable Tyre Company (Limited), 12, St. John's Lane, Liverpool.—Capital, £5,000 in £1 shares. Object, to adopt an agreement with D. L. Chalmers, and carry on the business of manufacturers of tyres, &c. J. B. Atherton, first managing director.

St. James' Motor Company (Limited).—Capital, £1,000 in £1 shares. Object, to acquire the business carried on by R. Medawar at 199, Piccadilly, W., as the Motor Drivers' Institute, and at 9, Carteret Street, W., as the Imperial Motor Garage Company. First directors, R. Medawar (managing director and chairman), W. C. A. Jollands.

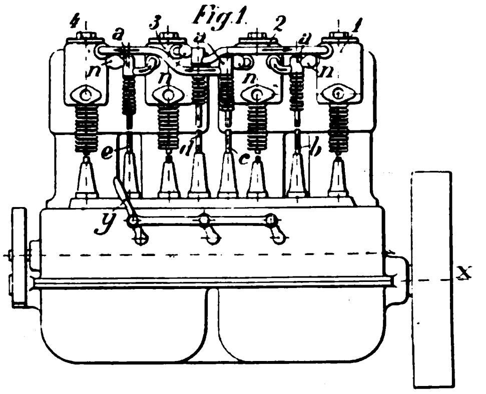
◆ ◆ ◆ ◆

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

2793. 10th February, 1905. Improvements in Automatic Igniting Devices for Explosion Motors having a Plurality of Cylinders. Marius Chevalier, 18, Avenue Laumiere, Paris, and Francois Regnaut, 68, Boulevard Sébastopol, Paris. This automatic ignition device for explosion motors is more particularly adapted for motors with four cylinders, although it may be used with motors having a larger or smaller number of cylinders, and the object is to utilise part of the exhaust gases from one or more cylinders for automatically producing the ignition of the fresh gases in the other cylinder or cylinders. There are five figures. Fig. 1 is a front elevation of the motor provided with the improvements. The invention is applied to a four-cycle motor with the four cylinders, 1, 2, 3, 4. An explosion is produced at each half revolution of the motor shaft, X, and these explosions usually take place in the cylinders in the order 1, 2, 4, 3. Each cylinder is provided at or near its upper part with a similar valve, *a*, in a valve-box connected to the cylinder by tubes surrounded by heat-insulating material in order to avoid cooling. In the order of ignition given above the tubes are so arranged that the first cylinder, 1, is connected with the second 2; the latter cylinder with the third 3 and the third cylinder back to the first 1. Between each cylinder and its respective valve is located a chamber, *n*, provided with an outer jacket or casing; the chamber being in communication with the cylinder by means of a valve. The valves, *a*, in the respective boxes are operated by rods, *b c d* and *e*, the rods being driven by cams mounted on the intermediate shaft of the motor on which are also mounted the exhaust cams. Each cam is formed of a group of cams of the same profile and of the same width as the lower end or shoe of the respective valve rod, each element of a group being connected or grouped together and keyed on the shaft at a different relative angle. These groups of cams rotate with the common driving shaft, and are adapted to slide longitudinally thereon with slight friction on a feather provided for each. This displacement is effected by means of a lever, *y*, and rods adapted to simultaneously operate the four groups of cams, a lateral displacement being thus obtained which causes the various cams of a group to act successively on a valve rod by the angular difference of each, and so produce the advance or retardation of the ignition by effecting an advance or delay in the opening of the valve communicating with the next cylinder. Each group of cams may also be made in one piece, having a helicoidal profile which produces the progressive advance or delay of the ignition. The pipes between the cylinders are provided with an insulating coating of asbestos for reducing loss of heat.—January 3rd, 1906.

Fig.1



29214. Arthur F. Scott, M.I.Mech.E., 171, Swan Arcade, Bradford. This invention relates to two-stroke-cycle internal combustion engines in which the exhaust is controlled by the piston, and its main object is to provide an engine working with gas or an explosive mixture in which a scavenging charge of air is admitted before the explosive charge enters, and which may be cheaply constructed. There are five figures. Fig. 1 is a sectional elevation. The motor cylinder, A, has an extension of larger diameter, C, and is fitted with a piston of two diameters, D and B, the part of larger diameter, B, having its underside open to the crank chamber, M, and forming a pump, while the upper trunk part, D, forms the motor piston. The lower part of the motor cylinder, A, contains exhaust ports, E, on one side and on the other side ports, O, connected with the crank chamber, M, by means of a separating pipe or passage, T, which has a spiral course as shown, so as to give length of passage. The motor and pump cylinders, A and C, contain respectively air and gas mixture inlet ports, K and L, and the motor piston, D, is provided with a deflector, D^3, on the top, and has a recess, J, in its side, and the whole is arranged, so that when the piston arrives at the top of the stroke the recessed port, J, therein connects the air inlet, K, with the port, O, leading into the top of the separating passage, T, and at the same time the pump part, B, of the piston uncovers the gas inlet, L, to the crank chamber, M, and the partial vacuum in the latter causes the scavenging and explosive charges to simultaneously enter the separating passage, T, and crank chamber, M, respectively, the proportions of the two charges being dependent on the size or openings of the two inlets, K (or O) and L. The scavenging air is thus held in the separating passage, T, and when the piston approaches the bottom of the stroke and has opened the exhaust, E, the air enters the cylinder by the ports, O, and is followed by the gas mixture when compression and ignition take place in the usual manner. On account of the pre-admitted air in the cylinder a small rich explosive charge may be used, and being held back this distribution tends to prevent any loss at the exhaust ports, and also to avert danger of explosion in the crank chamber when the piston uncovers the ports, O, owing to the interposing column of air in T. The scavenging air also tends to raise the mean pressure in the cylinder, and to enable the engine to run with greater range of load. When a single cylinder is used the inlets to same are provided with enough pipe to take the gases moved to and fro by the annulus, Z, of the piston, so as to avoid waste of gas.—January 3rd, 1906.

THE SARTHE CIRCUIT—the Course of the A.C. de France Grand Prix Race. We were enabled last week to give a sketch map and a series of extremely interesting scenes on the Sarthe Course, upon which the A.C. de France big race takes place this year, probably in June. Above we publish two more characteristic photographs on the Course. The top picture is a sharp corner in the village of Connere, and the lower picture shows a type of the many poplar-lined straight roads over which the competitors will race. This photograph depicts a stretch between Bouloire and St. Calais.

PASSING EVENTS.

The Motor Car in Elections. The election which has just been concluded, sensational as it has been in many respects, and notable as perhaps no election held in this country has ever been before for a complete reversal of popular opinion, will be memorable probably in the next degree for the *rôle* which automobiles have played in it. The automobile is, in fact, responsible, as far as we are able to judge, from the particulars and statistics that we have gathered, to a very large extent, for the enormous polls recorded. This is particularly the case in country districts. No distance has been too great for the cars under the control of enterprising election agents to fetch voters from, and on some occasions even those who are still on the register and have left the district have been fetched distances of a hundred or more miles. As far as an opinion can be formed at present, the results of the election, though shattering many hopes and proving a regular earthquake to one of the great political parties, inspires plenty of hope for the future of automobilism. Nearly 150 of the Members elected have expressed themselves as friendly or at any rate favourable to the new locomotion, and that is a fine phalanx, exceeding in numbers, we believe, the friendly Members in either of the last two Parliaments. The new Parliament will be probably in many respects unlike nearly all that have gone before it, but on the whole we are disposed to think that it will be less prejudiced, and prejudice, after all, has been the one great enemy of the movement. From an unprejudiced Parliament, in which there is a solid phalanx of Members favourable to the new locomotion, we have everything to hope. The most notable result of the elections has been the enormous increase in the number of representatives of labour, so-called, which of course really means the representation of skilled labour, of the engineering and allied trades. These Members, we feel convinced, will be among the very first, if they consult their true interests, to realise the importance of affording every support to a growing industry which already employs thousands of skilled British workmen, and will, if not hampered by restrictive legislation, in the future employ hundreds of thousands more. On the whole, therefore, there is no reason whatever to be pessimistic as regards the attitude in the new Parliament towards the automobile movement in Great Britain.

◆ ◆ ◆

Romantic Automobilism. "Qu'on est bien a vingt ans?" When one is twenty, when one is a king, when one is very much in love with a charming princess, and when as the single *amari aliquid* the ancient custom of your country makes it a violation of all precedent to sleep out of it (unless a regent is formally and solemnly appointed), then the motor car comes as a gift of the gods. The King of Spain has been giving a demonstration of its value in annihilating distance, the thing which every lover, whether in a palace or a cottage, always seems to want to do most. Princess Ena has been staying at Biarritz, probably because it is the most comfortable resort in the near neighbourhood of Spain, and that some quaint remnant of starched and stilted Spanish etiquette—the sort of thing that has survived from the days when the Spaniards invented the ruff and the pointed collar—prevents the future bride of the Spanish monarch from residing in Spain till she makes her formal entry into the country. So King Alfonso has had to return every night to San Sebastian, the nearest town in his own dominions. He has been apparently in the habit of remaining at Biarritz till about 12 o'clock at night, and usually arrives there at any time from 8 to 10 the following morning. Nothing but the motor car could have enabled him to accomplish this. Even the most prosaic dowager can imagine what it means to the young monarch to be able to race towards the French frontier with all the speed at which a high-class modern automobile is capable. If to be twenty, even in a garret, was to Beranger a recollection of delight (*dans un grenier qu'on est bien a vingt ans!*), what must it be to be a king—almost an absolute one—to be in love, and to have a 60-h.p. car!

◆ ◆ ◆

More of the Motor Barge. The "Duchess" of our canals—the motor barge fitted with a Thornycroft gas-plant—continues on her peregrinations, and has now successfully arrived at Manchester, having had many divers and weird adventures *en route*, not the least noticeable amongst which was her experience with the Board of Trade returns, which, according to Mr. Thomson's interesting report to the *Standard*, appear to have indicated that certain of the locks in Staffordshire are only 17 ft. 1 in. in width. The "Duchess" is 17 ft. 2 ins. in beam. In spite of the Board of Trade returns, however, she successfully got through these locks—a phenomenon which suggests that if we desire accuracy, even about the organisation of our own country, we shall soon have to obtain it from "foreign Consular reports." Anyhow the "Duchess" got through, and arrived in the Manchester Ship Canal, though she had to leave Birmingham with one blade missing from the 3-bladed propeller with which she originally started. In the Manchester Ship Canal she was requisitioned, besides the 5½ tons of bricks which she had carried from Birmingham, to tow two loaded and four empty barges—a task which, in spite of the handicap caused by the condition of her propeller—she accomplished most successfully. With this tremendous load she covered the 30¼ miles between Ellesmere Port, at the entrance of the Ship Canal, and Manchester, in five hours, or just a shade over an average of 6 miles per hour.

◆ ◆ ◆

A Hint of what is Needed. It will thus be seen that as soon as the motor-propelled barge got into a broad and comparatively deep waterway, she rather more than doubled her average speed on clear stretches between locks in other parts of the country. We do not gather that the difference in speed was altogether, or even mainly, due to difference in the general traffic. We believe the improvement in speed to have been due mainly, if not altogether, to the increased width and the increased depth of the waterway. The impedance produced by propelling a large barge, and particularly a barge towing other barges, in an ordinary narrow canal (increased when it has to meet or pass other barges), is enormous, and out of all proportion greater than what it is in relatively open water, where the back-wash off the banks, and the peculiar frictional effects produced by being very near the bottom, are practically non-existent. The performance of the motor barge on the Manchester Ship Canal indicates what the suction-gas engine can really do, for it appears to have done quite as well as a 30-h.p. steam-tug, in spite of the fact that one of the blades of its propeller had been broken off. The conclusion to be drawn, however, seems to be that if much improvement as regards the speed and capacity for dealing with the transport of goods is to be expected on our canals, if motor propulsion of barges is to be taken full advantage of, the canals themselves will have to be widened and deepened, in addition to the introduction of arrangements which we have recently alluded to, for diminishing the number of locks. If the canals are to remain as they are, little will be gained by having even 24-h.p. motors on board barges. The best method (under existing conditions) will be to have small motors which will propel barges at about their present customary pace, with a minimum expenditure of fuel. Of course, in general, provided that the whole power can be usefully employed, the bigger the engine the greater the economy of fuel effected, but if circumstances are such that the engine cannot advantageously put forth its full power, then economy lies in the direction of using engines of a size suitable to the conditions, and economising on their consumption as much as possible. Whether the suction-producer is suitable for smaller engines, whether its economy will not be seriously diminished if adapted to them, is at present a somewhat open question. But on its solution, we fear, depends the question whether our canals will be found of any great value for modern transport as they are at present, or whether, to make them of real national value and utility, the country will not be compelled to put its hand into its pocket, and hand out a very considerable sum.

Dusty Trophies.

When most low-lying country presents a pleasing lake-like appearance, and when most of the rivers that water the British Islands are flowing "in spate," one may discuss the dust problem more academically and in a more equable frame of mind, than when angry householders are writing to *The Times* in the dog days threatening to shoot at motor cars with buckshot, or to have district councillors smothered in the dust of the roads which they are supposed to keep in order. It is quite appropriate, therefore, that our contemporary, *The Public Health Engineer*, should recognise that this is the right time of year to lay plans for combating the dust fiend. Inspired with the best intentions and anxious to benefit the public health, the automobile movement, and the happiness and comfort of dwellers in country villages, *The Public Health Engineer* is offering medals of gold and silver (we mean both a gold medal and a silver medal) for the best papers dealing with the question. Without presuming to suggest that we should be awarded one of these trophies, we would offer the following remarks on the dust question for the consideration of our enterprising and public-spirited contemporary.

◆ ◆ ◆

Governing Principles.

As regards the great problem of eliminating dust from our high-roads, the period of mere discussion would seem to have been passed—*der Worte sind genug gewechselt*—and all experts and authorities who have really studied the question are coming to a concensus of opinion that dust prevention is of two kinds—the *preventive* and the *palliative*. By the palliative we mean applications of more or less tarry or oleaginous products, whether treated so as to be capable of mixing with water or not, applied to the surface of the road after it has been built up in the ordinary way. Of these, the most efficient in our experience during the summer months appears to be the simple treatment with hot tar, but, as has been pointed out sufficiently often by ourselves and others, this process suffers from the terrible disadvantage of making the roads a perfect quagmire of a peculiarly slippery and dangerous kind, as soon as winter conditions prevail. The other palliatives seem to be good only if frequently renewed, and then the cost becomes excessive.

◆ ◆

A Permanent Job Essential.

By the permanent recipes we mean either incorporating some material, preferably tar, with the actual road metal, and using material thus prepared to make up the road in the first instance, or adopting some such method as facing the road surface in a special manner, say, with small, smooth granite sets, as adopted successfully in Germany for some years past and recently on a short stretch in Liverpool. Both methods, when properly carried out, and when proper materials are employed, appear to be very satisfactory. They stop, or practically stop, all dust in the driest weather, and do not become unduly greasy in wet weather or in winter, while adding very considerably to the life of the road. The initial cost, however, is necessarily greater than the old-fashioned methods of making up roads with raw stones, spreading them with dirt, and rolling the whole mud-pie down flat with a steam roller. How far the initial cost will be curtailed by diminution of upkeep is one of those things on which adequate statistics are hardly yet available. But it is in such directions as these that we think the solution of the problem must be sought, even if the total cost is ultimately greater. We are by no means sure that increased total cost would really result. But even if the attainment of dustless roads (which should, be it understood, also mean mudless roads in winter), does prove more costly, it is—considering the great increase of locomotion in recent years—indispensable in the interests of the public health of the community, quite as much as it is called for by consideration for the comfort of dwellers on our roadsides. Under these circumstances, while recognising the intentions of the *Public Health Engineer*, we think that the direction in which the problem should now be attacked is rather by offering the medals or other encouragement for perfectations in the methods of the permanent kind to which we refer, or for the ascertaining of statistics regarding the relative cost of road making and upkeep on such principles, while if the *Public Health Engineer*, or any other public benefactors, wish to disburse further sums with the same benevolent purposes, they might dedicate them to the best scheme for propagating a knowledge of the principles of road building among district councillors, for—until further legislation takes the question out of their hands—it is our district councils who mainly stand in need of conversion and enlightenment.

⊛ ⊛ ⊛ ⊛

More New Laws Suggested.

It is stated that the effect of the large number of motor omnibuses that are now running in the Metropolis upon the general traffic has been so considerable that the L.C.C. will shortly consider whether any alterations in the laws upon the subject are necessary. We sincerely trust that this does not mean that any legislative attempt will be made to handicap the motor 'bus for the benefit of the electric tram.

THE 1906 SPYKER CARS.

High-class workmanship and materials in the construction of the chassis, silence in the running of the engine and transmission, and dustlessness in the motion of the car, have been three characteristic features of Spyker cars in the past, and so far at least as the last of these attributes is concerned, there is every sign of a still further improvement having been made in the design of the new models. Comparative dustlessness has hitherto been obtained in the Spyker car by the provision of a smooth metal sheath beneath the machinery and the absence of all low-hanging projections, such as tanks and tool-boxes become when carried at the rear of the frame; this year, however, the famous Dutch firm have clinched their acceptance of the efficacy of their experimental sheathing by forming it as a solid portion of the main frame, and the first chassis constructed in this manner was shown on the British Automobile Commercial Syndicate's stall at the last Olympia Exhibition, and is again on view at the Crystal Palace.

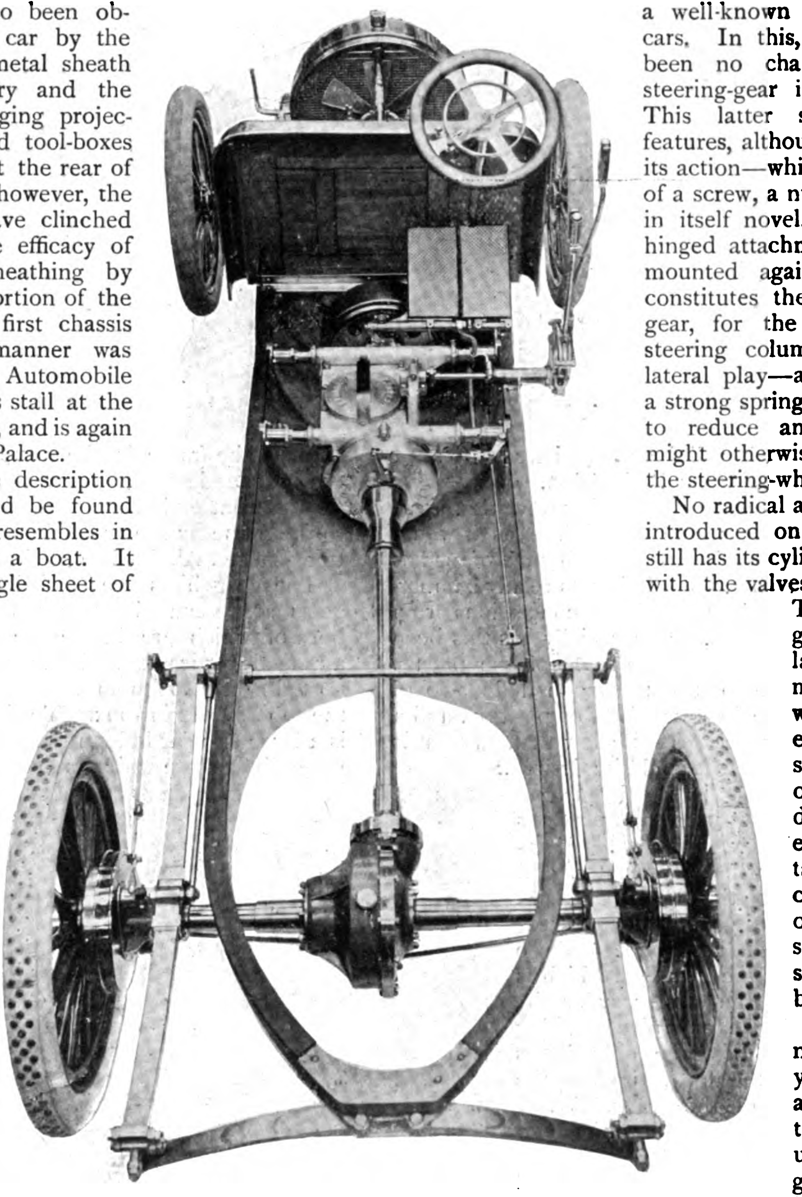

Fig. 1.—The 20-28-h.p. Spyker Car. View, from above, showing the peculiar frame, the suspension of the gear-box, and the "organ" pattern pedals.

No more appropriate description of the new frame could be found than in saying that it resembles in appearance the hull of a boat. It is pressed from a single sheet of steel, and the edges are curled over to form inverted channel section side-members, which are afterwards filled with wood to stiffen them. For the greater part of their length these side-members are straight, but at the rear they curve in towards one another until they nearly meet, and their ends are then joined by a casting, which also forms a bracket for supporting the transverse rear spring. Here again, too, the evolution of the design is obvious, for some time ago the Spyker Company commenced the practice of supporting the transverse spring—which, in conjunction with the great length of those on either side, is responsible for the very easy riding of the Spyker cars—on an overhanging bracket attached to the rear of the frame. This arrangement was found to be quite satisfactory, but the present system of curving the side member is obviously a natural development with a frame of this type, and one which gives a particularly finished appearance to the chassis. Strictly speaking, the frame has no transverse members, as such, but both the engine and the gear-box are supported in such a way that they supply the necessary rigidity.

The front axle is tubular, and it has cup-shaped ends for supporting the steering-heads in their spherical dust-proof casings, which are such a well-known feature on Spyker cars. In this, however, there has been no change, nor has the steering-gear itself been altered. This latter still has unusual features, although the principle of its action—which combines the use of a screw, a nut, and rack—is not in itself novel. It is the peculiar hinged attachment by which it is mounted against the frame that constitutes the real feature of the gear, for the device allows the steering column to have a little lateral play—against the action of a strong spring—which is claimed to reduce any vibration which might otherwise be transmitted to the steering-wheel.

No radical alterations have been introduced on the engine, which still has its cylinders cast in pairs, with the valves on opposite sides. The commutator and gear-wheel circulating-pump are mounted, as they were before, on the ends of the cam-shafts, which project out beneath the radiator in order to enable these important parts to be accessible from the outside. Needless to say, too, the crankshaft still runs on ball-bearings.

High-tension magneto ignition has this year been fitted in addition to that from the batteries. As usual, there is no governor, the engine being controlled by the driver from small levers above the steering-wheel. A curious feature, introduced as an experiment on one of the first of the new models, and illustrated in Fig. 4, is the spiral exhaust-pipe. It is constructed in this manner in order to give the exhaust-gases a swirling action which will disperse them more readily behind the car and so help them to prevent the formation of a vacuum, at high speeds, such as might tend to increase the dust raising. Forming the front of the bonnet is the honeycomb radiator, which is mounted on ball-socketed joints so that it has a certain freedom of movement and is not strained by any twisting of the frame. This ingenious system was, it will be remembered, a feature of the Spyker cars at the 1904 Paris Salon.

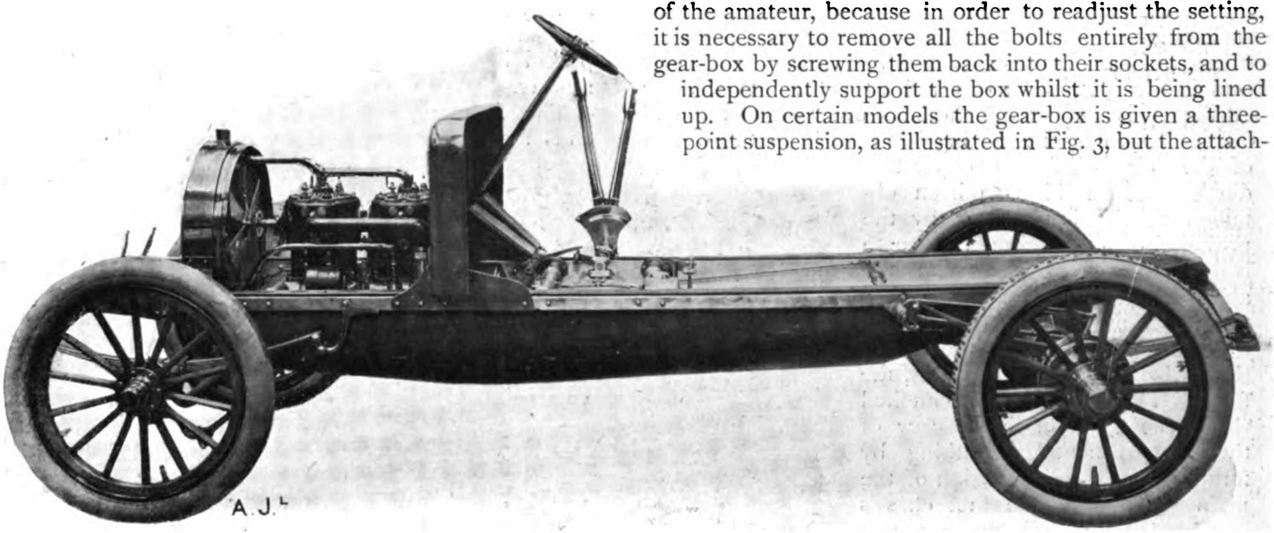

Fig. 2.—The 20-28-h.p. Spyker Car. Side view of the chassis showing the general appearance of the pressed frame.

This year, one of the most interesting novelties, apart from the frame, is the new type of pedal, or as it would appear on a finished car, the apparent absence of pedals altogether. Comfort has, considering its relative importance, generally received but grudging concessions from the designers of motor cars, and especially has this been so with regard to the size and positions of the pedals. By constructing them as part of the inclined floor-board they should at least be in a comfortable position, and a mere glance at our illustrations will show that, as regards size, they are everything that could be desired.

In the fly-wheel is a leather-faced cone-clutch of similar design to that used on previous models. It is of the external type, but has an enclosed spring which eliminates end thrust. By undoing the universal joint between the clutch and gear-box, the adjustment nut is ~~rendered~~ accessible. Close behind the clutch is the gear-box, which is supported in exactly the same way as the engine. It is a simple one piece casting forming a rectangular box, the only joints being the plate over the top casting and the caps over the ends of the shafts. When carried by a four-point suspension, the gear-box has four tubular brackets formed solid with it. Into these are screwed short steel bolts, A², which project from flanged sockets, A, attached to the frame. Having a thread formed on each end, these steel bolts are first screwed right home into the sockets, A, the gear-box is then set accurately in position. The bolts are afterwards screwed out of the sockets and into the brackets on the gear-box until they come hard up against collars formed on their shanks. This fixes them rigidly to the box, and lock-nuts are employed to make a rigid connection between the bolts and their steel sockets on the frame. Although this method of supporting the gear-box affords an easy means of alignment when fixing, it is yet sufficiently secure against the "good intentions" of the amateur, because in order to readjust the setting, it is necessary to remove all the bolts entirely from the gear-box by screwing them back into their sockets, and to independently support the box whilst it is being lined up. On certain models the gear-box is given a three-point suspension, as illustrated in Fig. 3, but the attachment to the frame is the same as that just described. An independent casting forms the "third point" bearing for the front end of the box, and this is rigidly attached to the frame by the two side sockets, A, and also by a third socket, A¹, fixed to the bottom of the frame.

The gear-shafts are carried on ball-bearings, and the gears are operated by means of a rack and quadrant, both of which are inside the box. The quadrant is arranged vertically, and the change-speed-lever is connected to it through an oil-tight bush which is well above the top of the gear-box. To facilitate inspection, there is a large circular hole in the top of the box, and this is closed by a plate which is merely held in position by a flat spring, and is thus instantly removable. Three

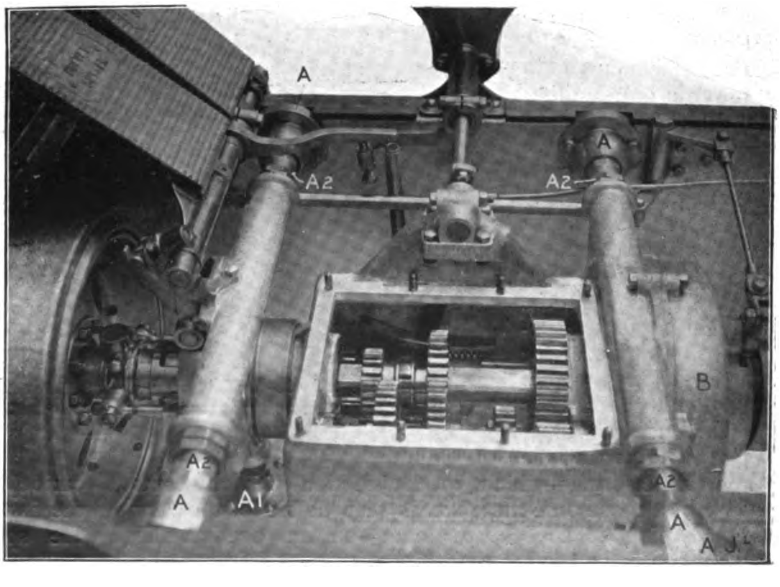

Fig. 3.—The 20-28-h.p. Spyker Car. View of the gear-box, showing the method of suspension and the operating quadrant inside the case. Behind the gear-box is an enclosed internal expanding brake, B.

speeds and a reverse are available from a single sliding member which carries two spur pinions. The direct-drive is obtained by engaging one of those pinions with an internally-toothed wheel, so that there is no jaw-clutch, as such—which shortens the length of the sliding member to a minimum.

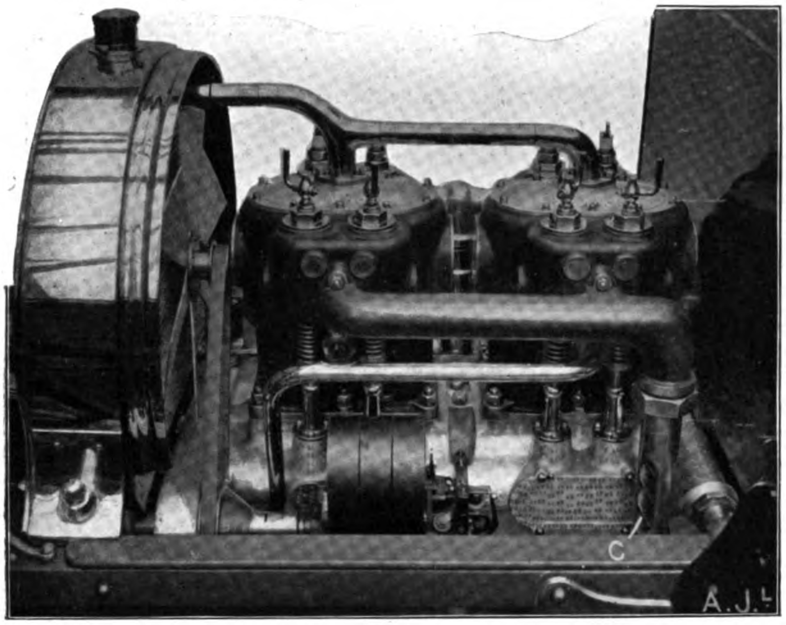

Fig. 4.—The 20-28-h.p. Spyker Car. View of the engine, showing the position of the high-tension magneto. In this view, which was taken from an exhibition model, part of the exhaust pipe is cut away to show the internal spiral passage, C.

Immediately behind the gear-box is the foot-brake, which is of the internal expanding type. It is entirely enclosed in a casing bolted to the gear-box, and this gives it a very clean appearance, which is typical of the Spyker design.

Owing to the proximity of the engine to the gear-box, the propeller-shaft is of considerable length. It has a universal joint at its front end, and is entirely enclosed in a substantial steel tube, which is bolted rigidly to the axle-casing at its rear end, and rides (on a ball-bearing) on the propeller-shaft itself in front. In this way it acts as a torque-rod, and counteracts the natural tendency for the axle-casing to revolve backwards. Although the back axle-casing is constructed in four parts, the Spyker Company have not yet adopted the horizontal division of the two central portions—which would allow a thorough inspection of the bevels without taking down the axle. The road wheels, however, are mounted on ball-bearings and run on tubular extensions of the axle-casing, and by so doing they relieve the internal shafts of anything but the torsional driving strain. Beneath the axle is a stay-rod for giving additional support to the central part of the casing surrounding the differential. Shackles being employed at both ends of the rear side-springs, some independent tie between the axle and the frame is necessary; this has been provided for by the short radius-rods which are attached, at their forward ends, to the same brackets as those which support the spring shackles. At their other ends they are attached to brackets which are fastened above the top leaves of the springs.

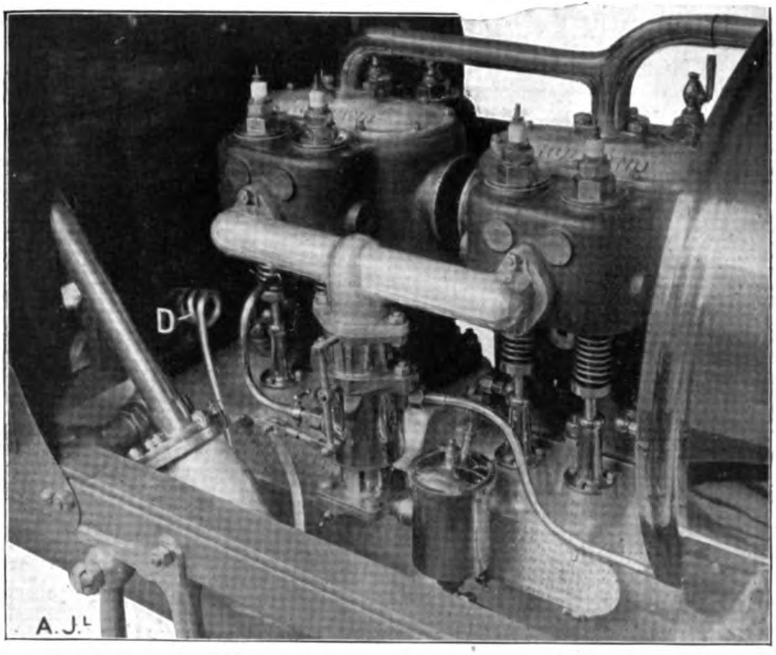

Fig. 5.—The 20-28-h.p. Spyker Car. View of the engine from the inlet-valve side showing the carburettor. Also prominent in this view is the coiled spring, D, used to support one side of the steering gear, the other side being hinged to the frame.

On the hub of each rear wheel are large internal-expanding brakes of the same pattern as that behind the gear-box. They are operated from a side lever, which is pulled backwards to apply them, and they are compensated by a steel cable in the orthodox way. An interesting point about the Spyker chassis is the construction of the wheels; they have fourteen spokes each, which is two more than is usual in standard practice, although some makers only fit ten.

For the next season the standard models are 12-18-h.p., 16-28-h.p., 20-24-h.p., and 25-38-h.p. Any of these, with the exception of the most powerful, can be supplied with the old type frame, if desired.

Bodies of the landaulette or side-entrance type are fitted to the standard chassis. One little fitting which has for some time past been used on Spyker cars is a luggage flap. It is formed by part of the panelling behind the rear seat, and is quite unnoticeable when not in use. Even when let down it is not large, but it is just sufficiently roomy to take a good-sized bag, and thus relieves the owner of the necessity of putting it in the tonneau—to the general inconvenience of everyone.

RESILIENT WHEELS.

(*Continued from page* 1436.)

THE HAWKSLEY PNEUMATIC WHEEL.

When writing the introductory chapter to this series of articles on Resilient Wheels, we referred, in general, to the occasional use of an internal pneumatic element in place of springs, and remarked in parenthesis that "It would not have been surprising to have found some resilient wheels using an internal arrangement of independent pneumatic cushions instead of springs, but we have not yet seen any spring wheel so constructed." This category is now represented, however, by the Hawksley wheel, in which the resilient element is supplied by four separate air-cushions symmetrically placed about—but not concentric with—the axle.

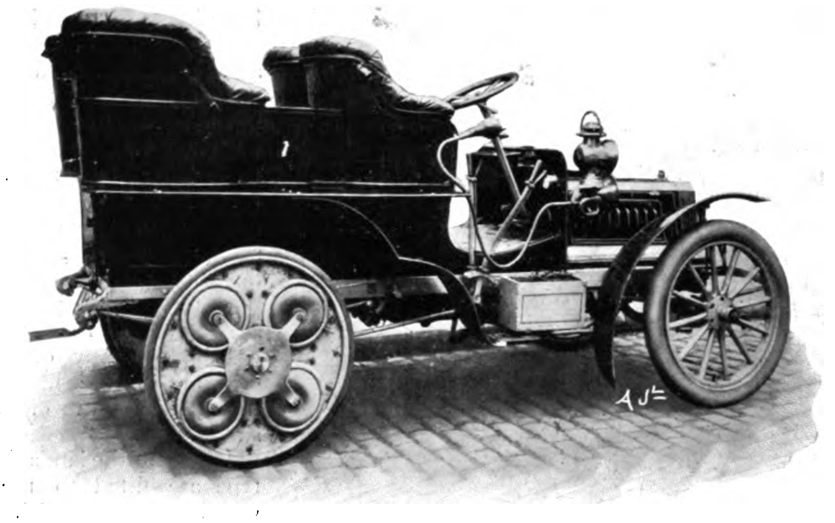

Fig. 1.—The Hawksley Wheel. View of a car fitted with a pair of these wheels.

So little is known about the theory of shock-absorbing devices in wheels that experimenters have to rely entirely on their own practical research to produce useful results. Thus most resilient wheels are, at present, quite as much the outcome of personal ideas as of scientific deductions from established data. There is little to guide the inventor of a pneumatic wheel; he may, for instance, fancy that the concentric arrangement of the pneumatic element is the secret of success or, on the other hand, he may not. Mr. Hawksley is of this latter opinion, but then the other side is not without supporters, as our articles on the subject have shown. There is one object, however, which Mr. Hawksley has had very prominently in view when constructing his wheel, and that is the acquisition of "softness," as distinct from mere "resiliency," in the running of the car. His idea has been, in fact, to imitate the effect of a partly-deflated pneumatic rather than the well pumped-up tyre, and, judging by some trials which we made recently, he has achieved this result to a far greater extent than might have been expected.

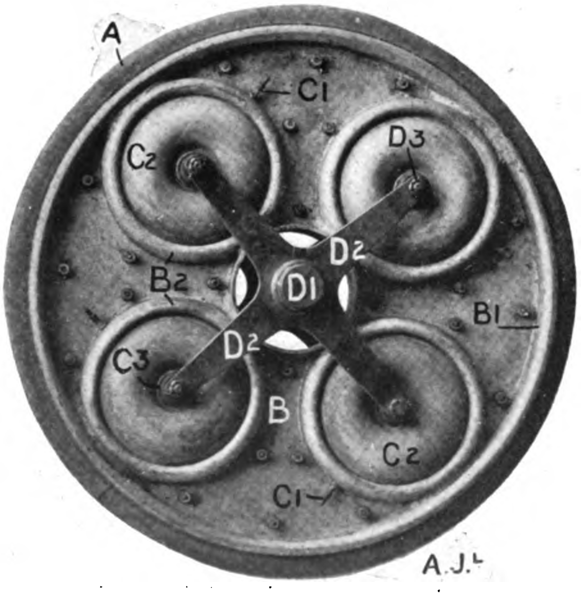

Fig. 2.—The Hawksley Wheel. View of the wheel complete, showing the four cushions and the driving arms in place.

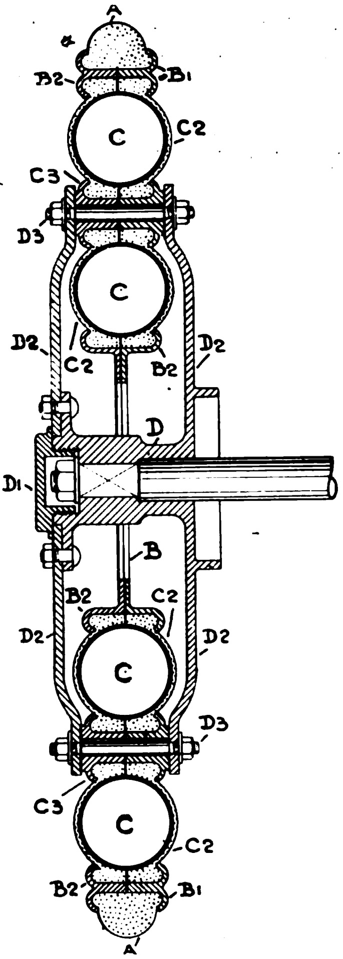

Fig. 3.—The Hawksley Wheel. Transverse section showing the arrangement of the various parts.

Our illustrations show very clearly the construction of the wheel and its component parts. The tyre, A, is mounted in the rim, A^1, which is formed by flanges on the peripheries of the two discs, B. Also carried by these discs are the four pneumatic cushions, each of which consists of an inner tube, or air chamber, C, and an outer cover, C^2, made in two parts. The halves of this outer cover are formed with beaded edges like an ordinary pneumatic tyre, and they are retained in place in much the same way. The cushions are, it will be noticed, annular in shape, and, through the holes in their centres, pass bolts, D^3, for the purpose of connecting them to the four-armed spiders, D^2, which are rigid with the hub, D. Small clamps, C^3, are used in order to secure the bolts, D^3, to the outer covers of the cushions.

All the weight on the wheel thus hangs directly on the fabric of the outer covers, and tends to pull the upper halves taut. By making these covers more or less concave, therefore, the range of motion between the two rigid members of the wheel can be varied to suit requirements. The air-chambers are only inflated to a pressure of about 20 lbs. per square inch for an ordinary touring car, and as a result the wheel, as a whole, is anything but stiff—especially in a lateral direction. This point is, in fact, one of the peculiarities of the Hawksley wheel, for the entire absence of rigid guides between the inner and outer members allows the wheel to slightly tip over obliquely to the axle whenever there is any tendency for it to do so. This is not, as a feature of construction, a point which would generally be considered favourable, but it does not appear to affect the control of the car, and it may even add to the softness of the action of the wheel. On this, also, is based a claim for reduced liability to side-slip, but we can offer no opinion at the present time on this matter.

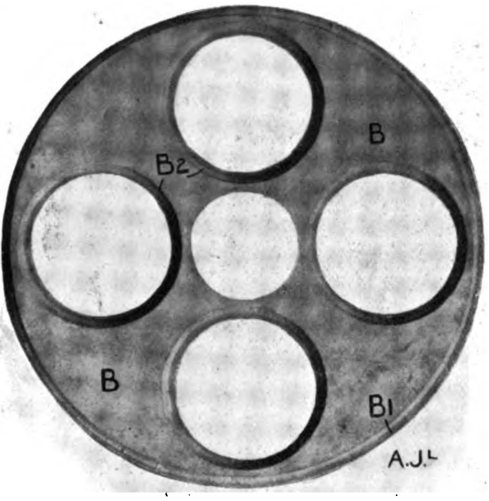

Fig. 4.—The Hawksley Wheel. View of one of the discs which carry the tyre and cushions.

Apart altogether from the shock-absorbing qualities of any wheel, there is, also, its practical durability to be considered. Obviously the outer covers of the cushions are called upon to withstand very severe strains, but knowing what the good pneumatic tyres of the present day will stand, there appears to be no reason why they should not be made to give satisfaction. At the present time we understand that the inventor has not experienced trouble in this respect, and it may be urged for these cushions that although they are probably subjected to more molecular friction, they are entirely removed from the rubbing action of the road, and as units they are inexpensive to replace.

In addition to their ordinary functions, the arrangement of the cushions in this wheel enables them to act, to a certain extent, as a "spring drive." Although not peculiar to resilient wheels as a whole, the use of the resilient medium for the purpose of neutralising the effects of a "fierce" clutch cannot but be considered as desirable in principle, especially for commercial vehicles, on which resilient wheels should find their widest field of usefulness.

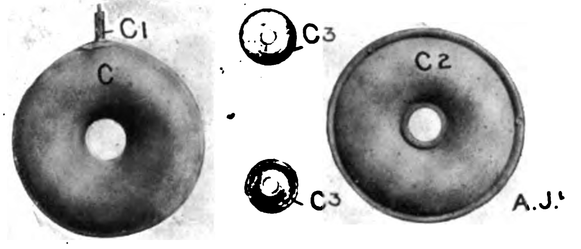

Fig. 5.—The Hawksley Wheel. View of one of the pneumatic cushions, C, together with one half of its outer cover, C^2, and the clamps, C^3, by which the driving arms are attached.

The Glamour of the Motor Car.

One does not like the sort of use to which the aureole of comparative respectability which surrounds the possessor, or alleged possessor, of a motor car, was put by the enterprising burglars who recently paid a visit to Miss Fox, of Hookwood, near Horley, who receives "paying guests." Seeing Miss Fox's advertisement, an adventurous "cracksman" of the name of Forsyth telegraphed that he was motoring to Horley and would call. He arrived on foot in the afternoon, and stated that his motor car had broken down at Redhill, and that he had come on by train, leaving the chauffeur with the car. He arranged with Miss Fox, and later in the afternoon introduced one Thomas, alleged to be his chauffeur. After dinner, Forsyth induced the lady to drink some whiskey, the naturally deleterious effects of which it is supposed he had increased by the addition of drugs, and she had to retire to her own apartments in consequence. In the meantime, Forsyth and Thomas decamped with articles valued at about £30, and some £4 10*s*. in money. Ultimately, however, they fell into the hands of Justice, through the suspicions of a country constable.

Hope for Veterinaries.

The veterinary surgeons who dined together at the Hotel Metropole, Leeds, recently, were rather pessimistic about the future of their profession, the motor car having made such inroads upon the business of the horse that they feared he would soon become extinct, and an important portion of the veterinary's business accordingly be lost to them. We would urge veterinaries generally, however, not to be too pessimistic, for the horse is not the only animal on whose ailments they have to depend, and if the numbers are diminished by the motor car, probably the horses who remain will be treated as pets, and then they will be ill nearly every day!

HIGH-TENSION MAGNETO IGNITION SYSTEMS.

(Continued from page 95.)

THE "CASTLE" SYSTEM—*continued.*

The Armature.

ALTHOUGH a laminated core is at present employed in the armatures of these machines, we understand that this will, in future, be abandoned in favour of a solid soft iron casting. Even now the side-plates, A^2, are each made in one piece, and are screwed directly to the end of the central core. In other respects the armature follows usual lines; the spindle is divided, and each half is screwed into a brass end plate by means of which it is attached to the armature-core. Ball-bearings, M^2, support the armature spindle at each end, and these are mounted on aluminium plates, M and M^1, which are screwed directly to the magnets. By simply removing four screws, and thus taking off the bearing-plate, M^1, the whole armature can be withdrawn; but a general inspection can be made even more readily by taking off the guard-plate above the armature, which is attached by four screws to the tops of the pole-pieces.

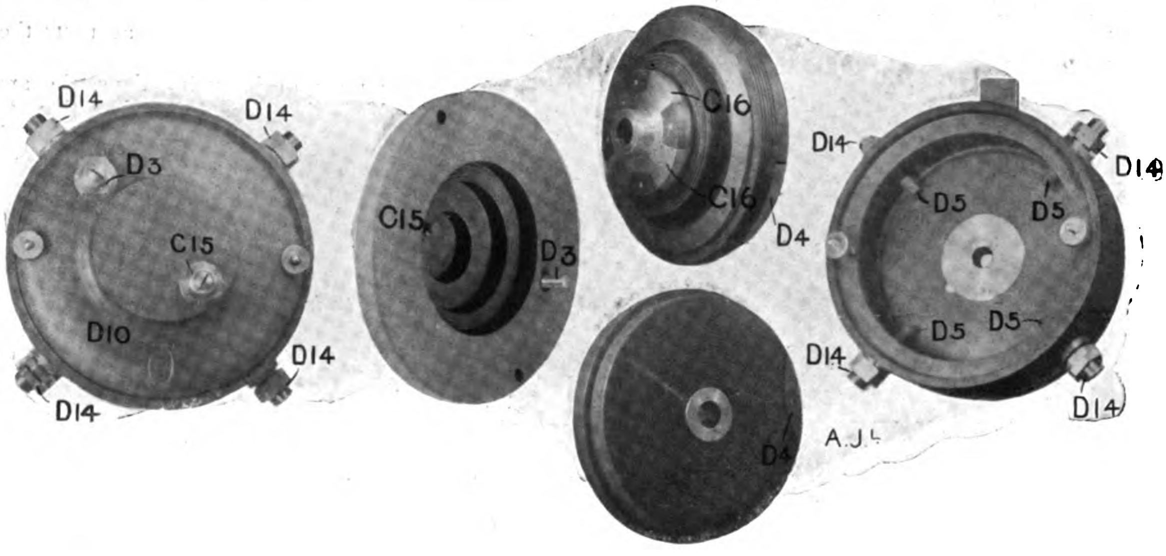

FIG. 4.—The Castle High-Tension Magneto System. View of the combined Distributor and Commutator, and of its component parts. The low-tension portion consists of the Brush, C^{15}, and the Contact Quadrants, C^{16}; the other brush, together with the Quadrant, D^4, belong to the High-Tension circuit.

For the purpose of attaching the driving-pinion, a separate tapered cone, B^2, is provided, and this is done on account of the timing gear which is introduced—on the spiral key principle—between the sleeve, B^2, and the spindle, B.

One end of the armature winding, C, is earthed to the core in the usual way, while the other passes through an insulating tube in the centre of the spindle, B, at the outer end of which it terminates in a hemispherical knob, C^1. Against this knob presses a samll spring contact, C^4, which is carried in the screw-cap, C^6, and the contact, C^4, is connected electrically to the terminal, C^{12}

The Coil and its Connections.

No low-tension gear as such being employed in this machine, the contact-maker, coil, and high-tension distributor are most suitably taken together as forming a combined unit. An illustration of the single coil appears in Fig. 1, while the multiple-coil is shown in

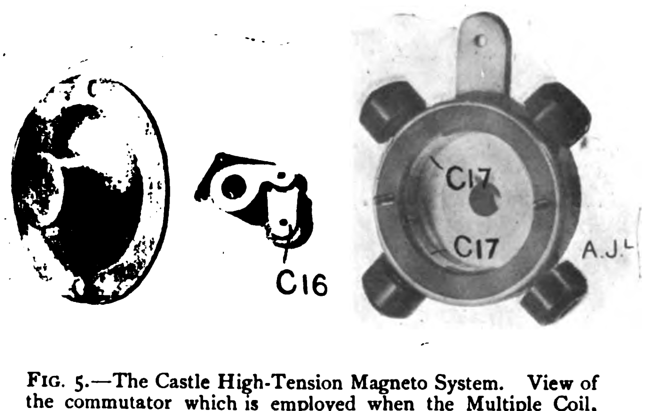

FIG. 5.—The Castle High-Tension Magneto System. View of the commutator which is employed when the Multiple Coil, shown in Fig. 6, is used instead of the single coil and high-tension distributor. This is of the ordinary roller contact type similar to those often used with ordinary battery ignition systems.

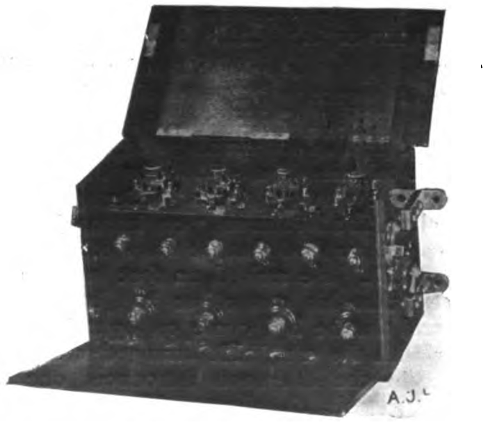

FIG. 6.—The Castle High-Tension Magneto System. View of a Multiple Coil for use with a four-cylinder engine, instead of the single coil and distributor, when this system is preferred.

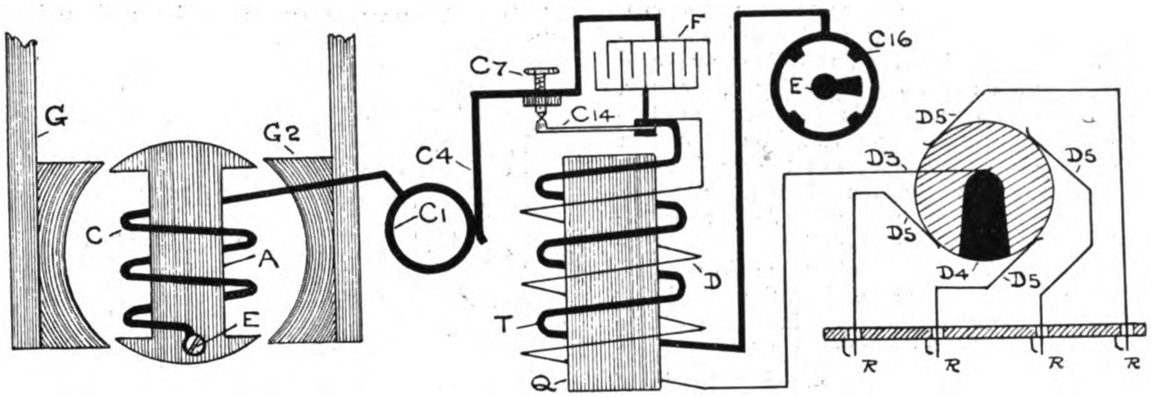

FIG. 7.—The Castle High-Tension Magneto System. Diagram of Internal Electrical Connections. It will be noticed that a trembler and contact-maker replace the usual form of positive contact-breaker generally fitted.

Fig. 5, but in either case they do not call for special comment, being similar in apppearance to the coils employed with ordinary battery-ignition systems. On the side of the box is the main switch for changing over from magneto to accumulators or *vice versâ.*

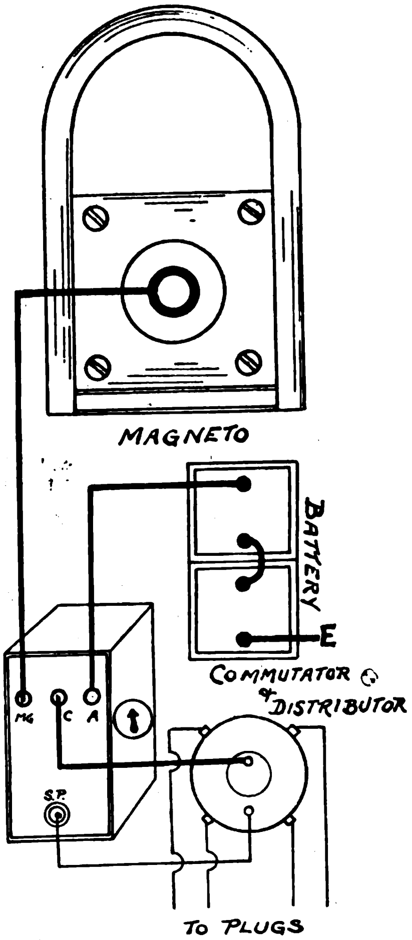

FIG. 8 —The Castle High-Tension Magneto System. Diagram of external connections showing how the magneto system should be installed when used in conjunction with ordinary accumulators. The main switch is on the side of the coil-box and the connections to it are permanent, being made internally. In this illustration, the letters against the terminals are those actually stamped on the case and do not apply to our table of reference letters.

When a multiple coil is used, the "commutator," illustrated in Fig. 6, is employed, but this is of familiar construction, and needs no special description. For use with the single coil, however, a very neat form of distributor, combined with low-tension contact-maker, is provided, this being illustrated separately in Fig. 4. From the terminal, C^{12}, on the magneto a wire is led to the terminal, C^{15}, on the outside of the case, and connected to this terminal, C^{15}, is a brush which presses against the rotating disc carrying the commutator segments, C^{16}. All these segments are, it will be noticed, connected to the centre boss which is fastened to the driving spindle, so that they make contact to "earth" and thus complete the primary circuit.

For the high-tension circuit a wire is connected to another terminal, D^3, also fixed to the cover, D^{10}, of the case. This terminal carries a brush, which presses against a brass ring connected to the distributor quadrant, D^4. As the distributor disc revolves, therefore, this quadrant, D^4, makes contact with each of the radial brushes, D^5, in turn, thus switching on the high-tension current to the ignition-plugs, which are connected to them by wires attached to the terminals, D^{14}. The condenser, F, is, of course, contained within the coil-box.

Timing the Ignition.

Although in any ignition system employing a trembler the time of ignition depends upon the setting of the contact-maker, yet when a trembler is used with a magneto it is desirable to ensure that some supplementary timing is provided for this also, in order that the arrival of the armature at its "maximum" position may coincide with the closing of the primary circuit by the commutator. In the Castle magneto this "timing" is obtained by the use of a spiral key between the driving-sleeve, B^2, and the armature-spindle, B. The key is connected to a rod, K^1, to which is attached a collar, K, for the purpose of engaging with the timing-lever. By moving the rod, K^1, in or out of the hollow spindle, B—which moves the key in its spiral slot, K^3—the setting of the armature relatively to the driving-sleeve, B^2, is altered and the "maximum" position is reached earlier or later in consequence.

The Electrical Connections.

There is nothing which demands special attention in the diagram of internal electrical connections shown in Fig. 7, with the exception, of course, of the trembler and "commutator," instead of the ordinary contact-breaker.

In Fig. 7 the circuit for the magneto only is shown, which is in accordance with our usual practice in connection with these particular diagrams. The actual connections for both circuits are given in Fig. 8, however, and from this diagram the combined magneto and battery ignition could be correctly installed on a car. In this view, too, the small letters against the terminals on the coil-box are those actually stamped on the case, and do not in any way correspond to our table of reference letters, which apply to all the other illustrations. The coil-box has, it will be noticed, three low-tension terminals and one high-tension terminal, the latter being connected to the distributor. On the side of the battery-box is the switch, but as the connections to it are permanently made inside, they need not trouble the motorist. The "earth" connections are, of course, made in the usual way to the frame of the chassis.

Table of Reference Letters for the Castle High-Tension Magneto System.

* * *

THE AUSTIN PETROL CARS.

A VERY complete catalogue giving detailed specifications of the cars which are being manufactured by the Austin Motor Company has now been issued, and can be obtained by all those who are likely to be interested in these new cars. As already announced by us, they comprise three distinct models, for the 25–30-h.p. car is either of the live-axle-type or is fitted with side-chains as may be required, and there is, too, the 15–20-h.p. live-axle vehicle. From the further particulars now available, it is evident that Mr. Austin has followed the most up-to-date practice in automobile construction and has embodied all such special features as are most appreciated by the public in cars of thoroughly orthodox design.

Thus, for instance, the engines have four separate vertical cylinders, with interchangeable inlet and exhaust valves, with five bearings to the crank-shaft, with an independent base-casting to the crank-chamber, and with easily removable cam-shafts; the main-clutch is of the multiple-disc type with metal to metal friction surfaces running in oil; the change-speed gear is constructed on "Mercedes" lines, with ball-bearings, with the sliding portion of the operating mechanism enclosed inside the gear-box, and with four forward speeds; and the pressed-steel frame is narrowed in front, is raised at the rear to clear the axle, and has its side-members formed in one piece with the under-frame carrying the engine and gear-box. Additional features are, moreover, numerous. Each shaft in the gear-box has three bearings, the box itself has no joint that can leak; the live-axles are connected with the main-frame by a torque-rod as well as by radius-rods, the "live" shafts inside the axles take none of the weight of the car, and all the road-wheels, as well as the easily-adjusted steering-gear and the steering-heads, have ball-bearings.

In connection with the engines, special care has been taken to enable absolute synchronism to be maintained at all times, for not only is the valve-gear (and the ignition-gear for the low-tension igniters) adjustable, but the lift of the valves, and the firing moment of each igniter, can be adjusted while the engine is running. A circulating pump constantly lubricates all the moving parts except the pistons, and these are fed with oil separately from a fitting on the dashboard. For maintaining any desired speed, a sensitive automatic governor is mounted on the spindle of the belt-driven fan, and this governor is connected up with the throttle-valve, with an accelerator-pedal, and with one of the small hand-levers above the steering-wheel.

Both engines run at a normal speed of 900 revs. per min., and both have a stroke of 5 ins. The smaller model, with its 4⅛-in. cylinders, develops 22-b.h.p. at that speed, and the larger engine, with its 4½-in. cylinders, gives 32-b.h.p. All the standard cars have a wheel-base of 9 ft. 9 ins., with a track of 4 ft. 7 ins., but the 15–20-h.p. vehicles have 12-gall. petrol tanks, as against 15-gall. tanks on the 25–30-h.p. models, and their tyres are 880 mm. by 120 mm. and 870 mm. by 90 mm., as against 920 mm. by 120 mm. and 910 mm. by 100 mm. On the chain-driven car, the differential-countershaft is contained inside a separate casing, which is quite distinct from, and is some distance behind, the gear-box.

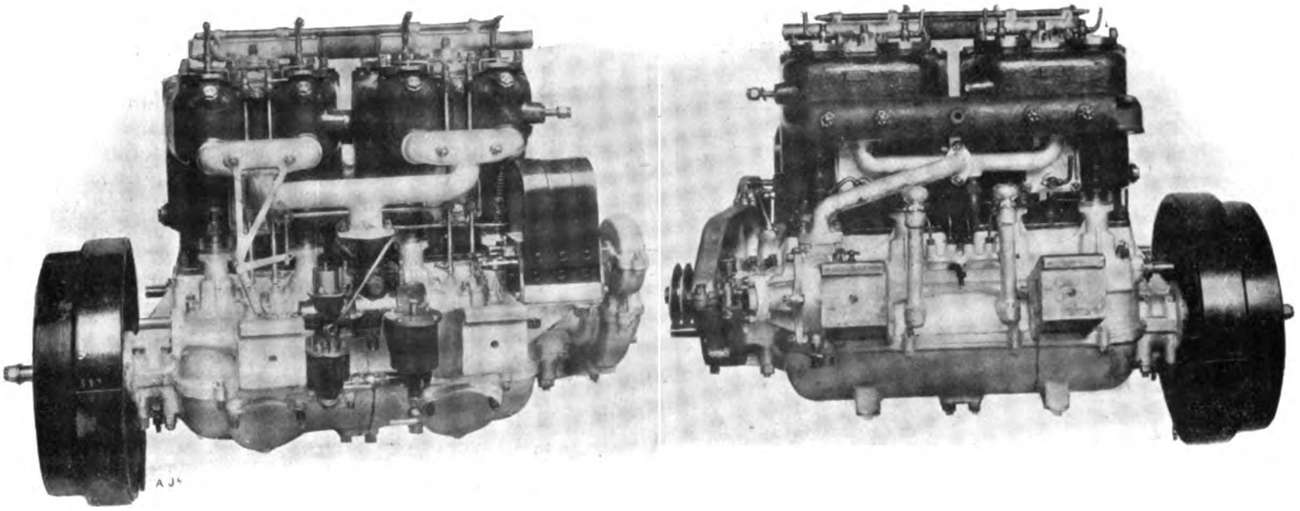
* * *

Brighton Motor Road "Finance."

THE Bill for legalising the egregious London-Brighton motor road project is incurring pronounced opposition, even at this early stage of the proceedings. In addition to the objections to it chronicled by us last week, it has further been opposed by Lord Hylton and Mr. Richard Trower on the ground of not complying with the Standing Orders, and was further objected to by Parliamentary agents appearing for the opposition on the ground that the prospects of the scheme were so problematical as to render any examination unnecessary. The most serious objection of all, however, was that the necessary deposit money, which in accordance with the Standing Orders must be found before the examination of the Bill, had not been obtained, and it is reported that the promoters of the project are still running round the City endeavouring to obtain the money—a condition of affairs which caused one of the representatives of the objectors to protest that if the application for an adjournment for a week were granted, it would be used by the promoters solely for the purpose of endeavouring to obtain money that ought to have already been subscribed. That the prospects of obtaining it after this publicity are therefore not very rosy, goes without saying, and the *Financial Times* comments on the failure to produce the required deposit, as follows:—

> "This is not surprising, in view of the suggested particulars in regard to this absurd promotion which we placed before our readers on the 4th."

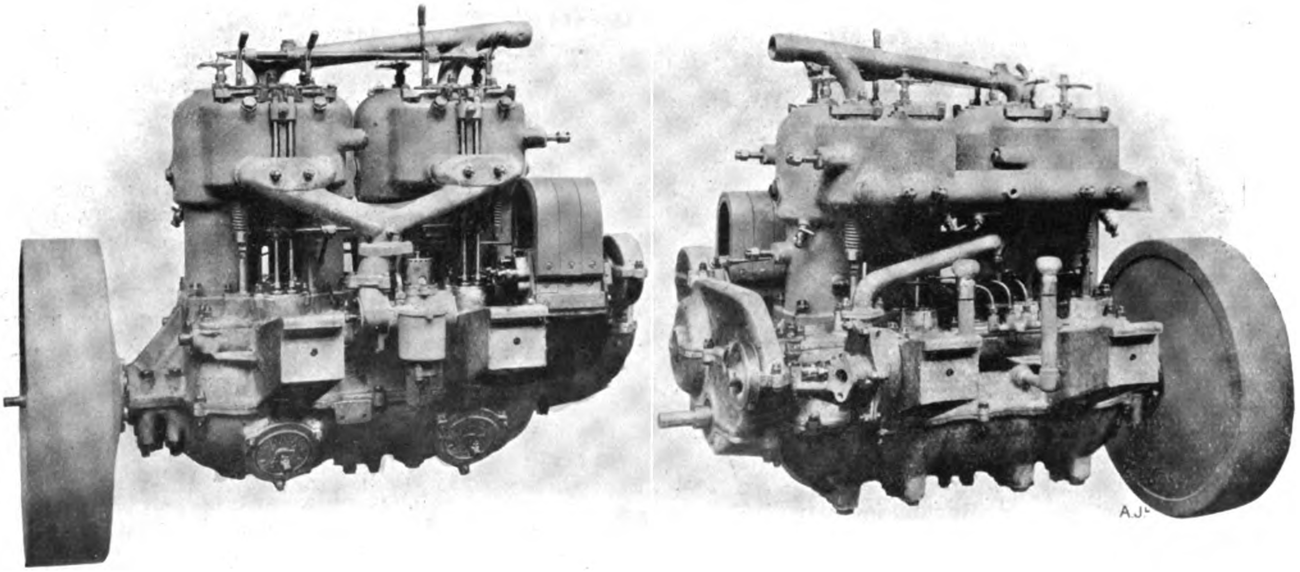
THIS YEAR'S 30-H.P. AND 40-H.P. CROSSLEY ENGINES.



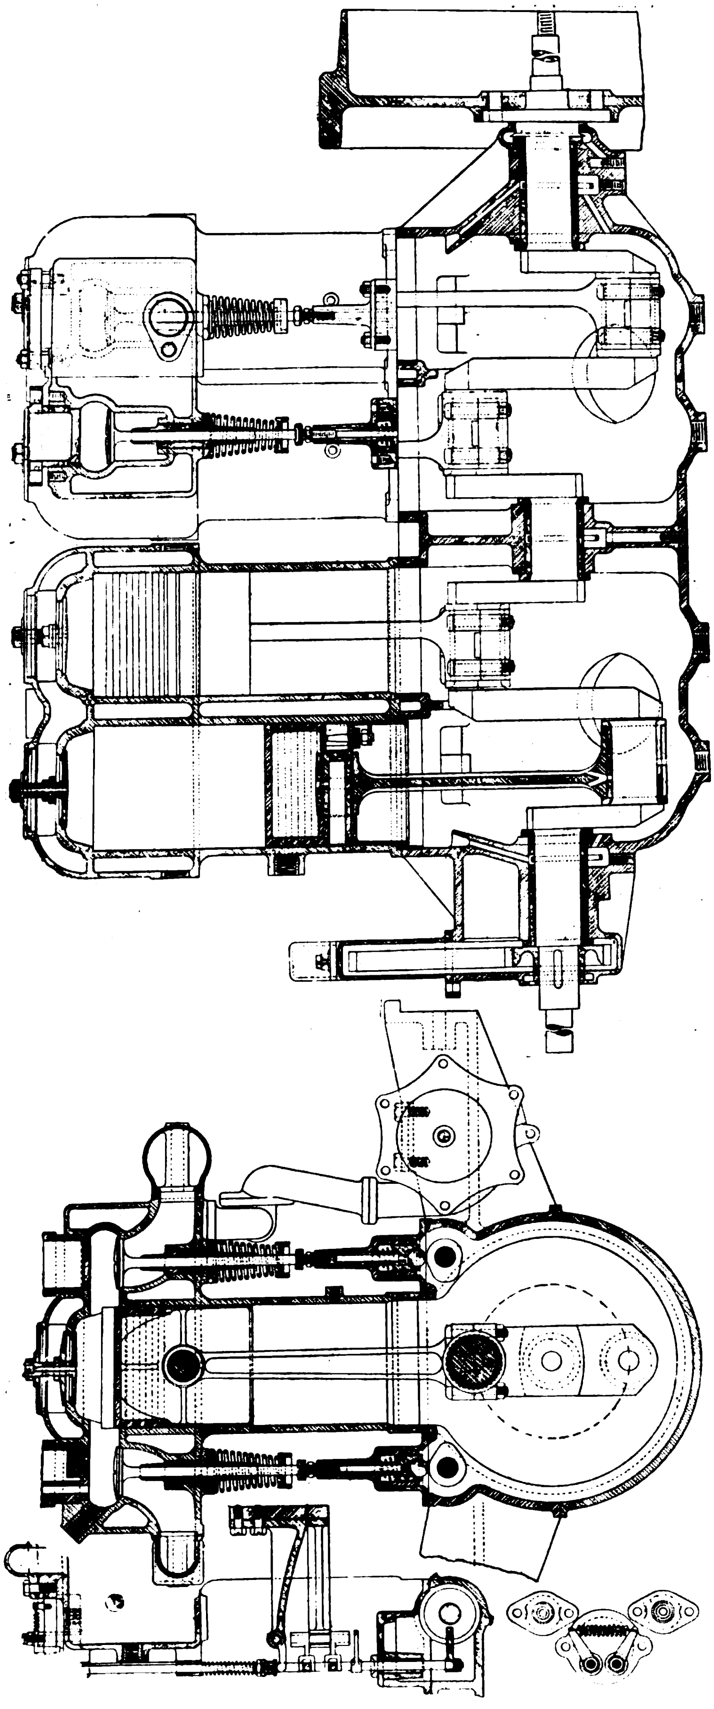
Figs. 1 and 2.—The 30-h.p. Crossley Engine. Views from each side, with the carburettor, magneto, and circulating-pump fixed in place. The cylinders have a bore and stroke of $4\frac{5}{16}$ in. and $5\frac{1}{8}$ in., respectively, and the normal speed is 900 revs. per min.

ON November 4th last, an illustrated description was given in these columns of the improved chassis that has been adopted for the 1906 Crossley cars. At that time, however, no photographs of the new 40-h.p. engine were available and we were consequently unable to deal with it in any detail. Similarly, the previous week, we had to content ourselves with briefly mentioning the chief respects in which the earlier 22–28-h.p. engine (now 30-h.p.) had undergone modification, and had no illustrations with which to show its present appearance. Our readers will consequently welcome the photographs and drawings which are now reproduced, for these include two views of each engine—the present 30-h.p. and the new 40-h.p.—as well as two sectional drawings of the more powerful model.

In a general way, both engines resemble that originally introduced by the celebrated Crossley firm early in 1904, at which time (on February 13th) we published very full particulars concerning its design and construction, but the well-known designer, Mr. J. S. Critchley, has since then added improvement after improvement in matters of detail, with the result that the latest models are even more efficient, noiseless, and flexible than before. The cylinders of the 30-h.p. engine, which is shown in Figs. 1 and 2, are now bored out to $4\frac{5}{16}$ ins., but the stroke ($5\frac{1}{8}$ ins.) remains the same. Its reciprocating parts have been reduced in weight, in order to enable it to run faster, and several other alterations have been made with a similar object in view.



Figs. 3 and 4.—Two views of the new 40-h.p. Crossley Engine, which—in spite of its greater power—occupies the same space as the 30-h.p. model. The bore of the cylinders is $4\frac{3}{4}$ ins., the stroke is 6 in., the normal speed being 900 revs. per min. An improved form of carburettor is used, in which the fuel, as well as the air, is automatically controlled by the suction of the engine.



Figs. 5 and 6.—Sectional Drawings—transverse and longitudinal sections—of the 40-h.p. Crossley Engine, showing the internal construction and arrangements of the various parts. On the left, in Fig. 5, is a separate drawing of the ignition-gear, with its disc cam, for one cylinder.

A comparison of Figs. 3 and 4 with Figs. 1 and 2 will show the differences that there are in the design of the 40-h.p. engine, the most striking of these being the relatively small size of the new model, in spite of its larger cylinder dimensions. The 40-h.p. engine has 4¾-in. pistons, the stroke of which is 6 ins., and yet it fits into the same chassis as the smaller engine, for the cylinders themselves are not only closer together, but the valves are brought in much nearer to the centre.

Other points are that the water-jackets do not extend so far down from the cylinder-heads as they do on the 30-h.p. engine, that a modified form of carburettor, having an automatic adjustment for the petrol-jet as well as for the auxiliary-air, has been adopted, that a neater form of crank-chamber has been employed, and that the induction-pipe affords a more direct passage for the explosive mixture.

These photographs, taken in conjunction with the sectional drawings given in Figs. 5 and 6, show the construction and arrangement of every part, and it is therefore quite unnecessary for us to enter into any lengthy description concerning them. It may, however, be useful if we draw attention to a few of the characteristic features of both engines. Thus, for instance, it will be noticed that the spur-wheel driving the low-tension magneto, on one side, and that driving the centrifugal pump, on the other side, are enclosed in the same oil-tight casing as the three wheels by which the cam-shafts are connected with the crank-shaft. Further, it will be noticed that the low-tension igniters form inspection-plugs above the inlet-valves, that an automatic governor acts upon a butterfly-valve in the induction-pipe to prevent "racing," and that provision is made for "timing" them by sliding the vertical rock-shafts up and down; these igniters are actuated by disc-cams on the cam-shaft, and, as is the case with all the valve-gear, great care has been taken to facilitate accurate adjustment and ready accessibility. Another point, which might escape notice, is that high-tension ignition-plugs can be fitted if required, the screw-sockets for these passing diagonally into the inlet-valve-chambers.

The 40-h.p. engine, in particular, is remarkably well designed throughout, and has ample wearing surfaces for all the various bearings. It develops 35 b.h.p. at a speed of 800 revs. per min. or about 42 b.h.p. at 1,000 revs. per min. Both engines are, in fact, well worthy of the celebrated Crossley firm, and are admirably calculated to maintain the world-wide reputation they have earned with their other and heavier types of gas engines.

THE CRITCHLEY LOW-TENSION IGNITION GEAR.

Although not actually fitted at present to the Crossley engines, of which a description has just been given above, the accompanying drawings show a new form of ignition gear applied to an engine of similar type, this device being one of Mr. J. S. Critchley's latest inventions. Its chief object is to simplify the mechanism by which the low-tension igniters are actuated from the cam-shaft, and to operate the four igniters on a 4-cylinder engine by two cams instead of four. But it also has the effect of rendering the usual valve-gear much more accessible, since the whole of the ignition mechanism is arranged above the cylinder heads. Fig. 1 is a plan view of an engine in which the igniters, A, are placed immediately over the inlet-valves (in precisely the same way as on the 40-h.p. Crossley engine), and the exhaust-valves lie above another main cam-shaft on the opposite side. Both cam-shafts are indicated in Fig. 2, which is an end elevation of the upper portion of the engine with the ignition mechanism shown sectionally. From these drawings it will be noticed that a vertical shaft, B, is led up, inside an oil-tight casing, from above the inlet valve cam-shaft, between the two cylinder-castings, and that this vertical shaft is driven by bevel-gear, B³, from the horizontal shaft. At the top of the shaft, B, are the two ignition-cams, B¹ and B², the former being immediately above the latter; the cam, B¹, actuates the igniters of the two inner cylinders, and the cam, B², operates the the two outer igniters.

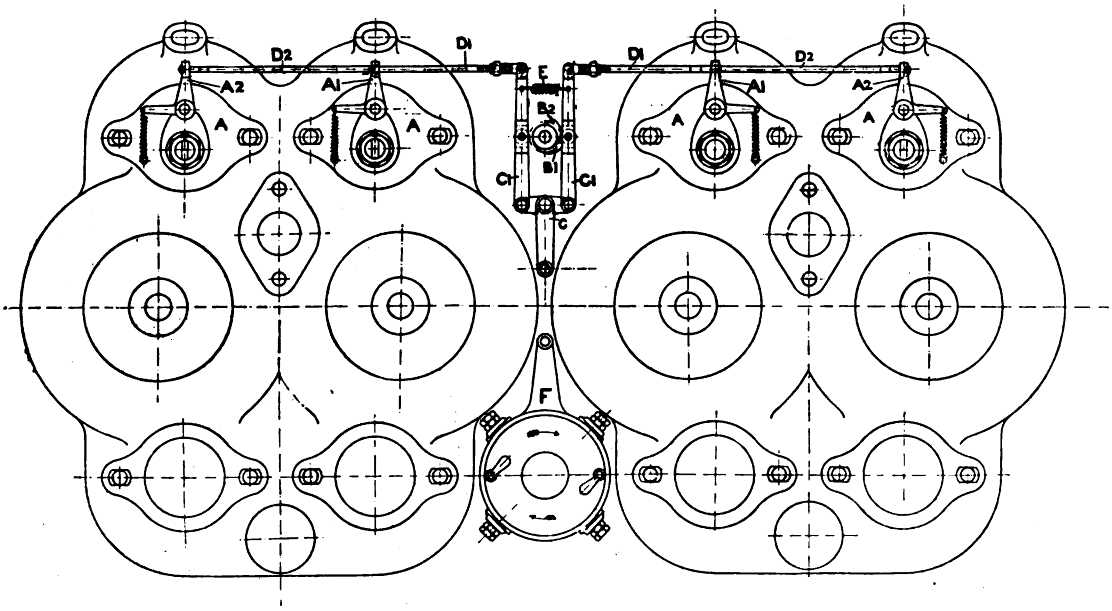


Fig. 1.—Plan of a 4-cylinder petrol engine, fitted with the new Critchley ignition-gear. All four igniters are operated by two cams mounted upon an enclosed vertical shaft.

For this purpose, as also for "timing" the ignition, a pivoted lever, C, is mounted about a stationary pin at the top of the casing, and to each arm of this lever are hinged a pair of links, C¹ and C². These links, C¹ and C², carry small rollers that engage with the cams, B¹ and B², respectively, so that the upper cam tends to force the links, C¹, outward as it revolves, and the lower cam has the same effect on the links, C². A further point that should be noticed is, that when the pivoted lever, C, is rocked about its axis, the moments at which the cams come into operation are rendered either earlier or later for all four of the links. The two upper links, C¹, are normally held against the cam, B¹, by the spring, E, and there is a similar spring introduced between the lower links, C², these springs tending to give a very quick throw-off action as the rollers slip off the sharp edges of the cams. Each of the igniters has its own spring for bringing the contact-points together, but it is the much stronger springs, E, that strike them apart, for the two links, C¹, are connected with the rocker-arms, A¹, of the igniters on cylinders Nos. 2 and 3, while the lower links, C², are similarly connected with the other

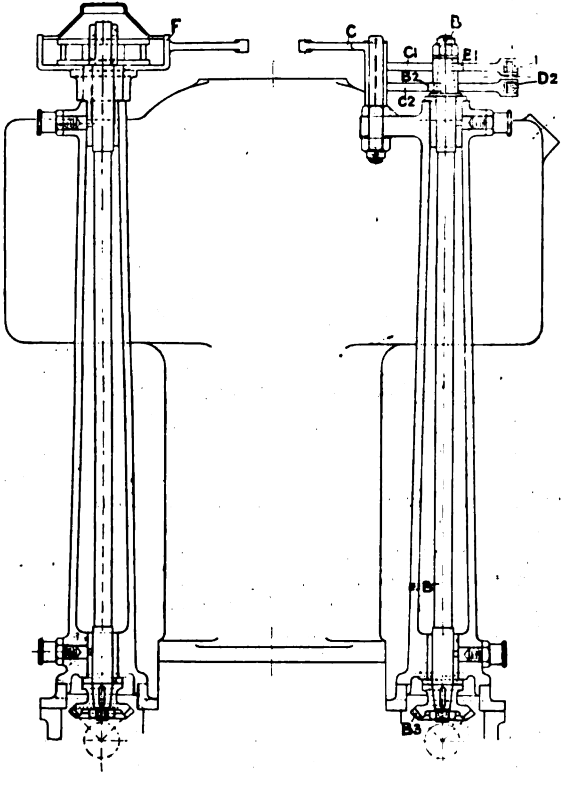

Fig. 2.—End elevation, with the ignition-gear in section, showing the Critchley low-tension operating-mechanism fitted to a 4-cylinder petrol engine.

rocker-arms, A^2, by rods, D^1 and D^2, respectively. Such is the shape of the rods, D^1 and D^2, that they merely allow the igniter-springs to bring the contact-pieces together, when the cams, B^1 and B^2, relieve the rods from the pressure of the springs, E, but the ends of the rods engage with the rocker-arms, A^1 and A^2, when making their quick-return stroke. In our drawings of this particularly neat mechanism, the engine is also shown with a similarly arranged shaft above the exhaust-cam-shaft for carrying the commutator, F, but this is, of course, only needed if an auxiliary, high-tension, battery system is employed as well.

* * *

THE CRYSTAL PALACE SHOW.

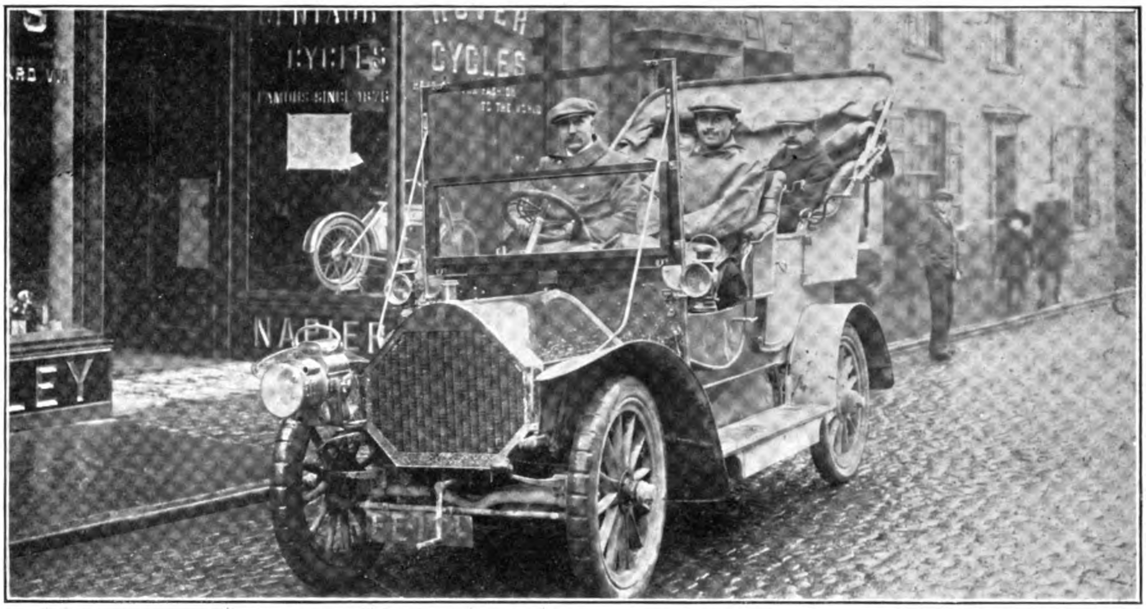
The Fifth Annual Automobile Exhibition at the Crystal Palace opened on Friday, the 26th ult., and closes to-day (Saturday). No one can have expected the Show to be remarkable, either for the completeness or the novelty of its exhibits, and while it does not altogether belie these anticipations, yet there seemed this year to be a stronger breath of life about the place than was the case last year. It is a small collection of cars—very small when compared to the glories of the past—and yet a man might do far worse than go there to buy, for there are several first-class machines in evidence, and there is not that confusion caused by mere multitude which must often have proved a disappointment to some would-be purchasers of good cars. There are several interesting exhibits which nevertheless are not fresh, but there are also others which have not previously been on view.

Humber Cars.—On the Humber Stall, for instance, is a new 16–20-h.p. chassis which has just been introduced for the next season. It is built on similar lines to the previous live-axle model, but embodies several important modifications in detail. As at present constructed, it has a pressed-steel main frame, and an angle-iron under frame for the engine and gear-box. Each cylinder of the engine is cast separately, and the power is transmitted through a leather-faced cone-clutch, which can be easily dismounted after disconnecting the universal joint between it and the gear-box. No less than nine ball-bearings are employed to support the gear-shafts, there being a double-row bearing at each end and an intermediate single bearing on the through-shaft. Two universal joints are fitted to the propeller shaft, and there is a horizontal joint between the two central members of the back-axle casing. Tubular extensions of this casing support the road-wheels and hinged radius rods transmit the drive to the frame; the torque is counteracted by an independent triangular stay. Altogether the Humber cars are, at the present day, among the most notable on the market, and they should establish a sound reputation for the firm which is using its utmost endeavours to supply a sound car at a low price. On the stall, too, are displayed the parts of the 10–12-h.p. Humber car driven by Mr. R. M. Wright on the 5,000 miles trial. Particulars relating to this run appear elsewhere, but it may again be mentioned that the various parts are all in good condition after their test, some slight signs of insufficient oil on a connecting-rod big end, and the results of a little hurried gear changing being all that is at all noticeable.

Vinot Cars.—Among motor vehicles which have sprung quickly into prominence and into no little popularity as well is the Vinot car. It is but a short time since T. J. Harman and Co. introduced them into this country, but from the first they gained favour, and to-day they take a high position among cars of their class. No doubt the excellent performance of their Tourist Trophy car was not a little responsible for this, but there has always been evidence of good workmanship and no little ingenuity on the part of the manufacturers. One of the most peculiar features about this car is, as our readers are aware, the change-speed lever, which operates a gear-box of the divided sleeve, or "Mercedes," type without the use of a sliding lever — which fact is naturally of additional interest at the present moment when the situation with regard to the so-called "gate" system is beginning to get interesting from the patent point of view. Another feature of the chassis is the self-aligning clutch, and in connection with this an improvement has now been introduced by which the clutch-cone is prevented from tilting out of truth when released from contact with the outer member. This is accomplished by the simple expedient of fitting a collar on the clutch-shaft immediately behind the inner member; when, therefore, the clutch is disengaged, the cone is forced backwards against this stop which keeps it in proper alignment so long as the clutch is free.

Pilain Cars.—Although the Pilain cars have been exhibited in England previously, the 40–60-h.p. model has hitherto only been shown in Paris. It differs entirely from the other models, but the prevailing idea of having a direct-drive on more speeds than one is, of course, characteristic of it also. In this car there are three speeds and a reverse, and every one is a direct-drive. On the end of the propeller-shaft are three bevel-pinions which mesh respectively with three bevel-wheels, of varying diameter, riding on the back axle. Either of these wheels can be locked to the shaft by means of sliding keys operated from a side-lever in the usual way. A differential-gear is introduced between the bevel-wheels and the axle proper, and the reverse is obtained by a fourth bevel-wheel placed on the opposite side and meshing with the "low-speed" pinion. Three-quarter elliptic springs support the frame at the rear, and the propeller-shaft casing, which terminates at its upper end in a large ball-socket bracket attached to a cross-member of the frame, takes the place of any radius or torque-rods.

Darracq Cars.—On the Darracq Stall is one of the new 20–32-h.p. chassis, which embodies the latest modifications of this enterprising firm. The new engine has an extremely neat appearance—especially on the show chassis, where it is finished off with an oxydised surface. All the valves are on one side, and the leading characteristic of the design has been to make the cam-shaft which operates them as useful as possible. For this reason the igniters are also on the same side, but, as usual, it has not been found convenient to operate them absolutely direct from the cam-shaft. A very neat arrangement has been adopted, however, the small rock-levers which are interposed between the lower ends of the tappet-rods and the cam-shaft, to get over the difficulty, being enclosed in small brass covers, which are quite in keeping with the general cleanness of design.



5,000 MILES RELIABILITY TRIAL.—Mr. R. M. Wright and his 10–12-h.p. Humber Car, with which he has just completed a 5,000 miles reliability run, finishing at the Crystal Palace at midday on Saturday last. We give particulars of Mr. Wright's performance on page 142. Except for the replacement of a commutator ring, no troubles were experienced, and, in spite of exceeding bad roads, only five punctures occurred, the Dunlop tyres equalling the good behaviour of the British-built car itself.

Mounted in front, on a transverse-shaft, which is skew-gear driven from the cam-shaft, are the low-tension magneto and the gear-wheel circulating pump. It is one advantage of using skew-gearing, that the driving and driven shafts can cross one another, and this fact has been taken advantage of on the Darracq car by carrying the cam-shaft out beneath the radiator and mounting on its projecting end the commutator for the high-tension ignition system. There being still the other end of this ubiquitous cam-shaft unemployed, the designers have saddled it with the work of driving a neat little centrifugal oil-pump which supplies the lubricant to the sight-feed fitting on the dash. Incidentally it may be mentioned that the mechanism for timing the low-tension igniters is also operated through the cam-shaft.

In the fly-wheel is the usual cone-clutch, but this, in the present model, has springs placed under the leather to render it less fierce. Close behind the clutch is the gear-box, and a long propeller-shaft transmits the power to the live-rear-axle. One universal joint is provided in the propeller-shaft at its upper end and there is a flexible box-coupling near the back axle. The rear wheels run on tubular extensions of the axle casing. A peculiarity about the frame is that, at the rear, the side members are not only bent upwards over the axle but inwards also, this latter being for the special attachment of the body.

Rochet-Schneider Cars.—Another new model of considerable interest is the live-axle Rochet-Schneider. It has an 18–22-h.p. 4-cylinder engine which, in general design, does not differ from the previous models; the method of control has been changed, however, and instead of the long levers projecting from the dash, the manufacturers have adopted the less striking, but more accessible, system of placing them above the wheel. Quite a new design of gear-box, too, has been introduced on this model. It appears exceedingly small, because the lay-shaft is placed beneath instead of to one side of the through-shaft. A transverse semi-elliptic spring is used in conjunction with the ordinary side-springs to support the rear of the chassis, but a noticeable feature about all these springs is that they are much smaller and have a greater camber than those usually employed on cars of this type.

Itala Cars.—No stand in the Palace is more artistic, and on none are the exhibits more interesting, than that of the Fabry Automobile Company. On it is the Itala 100-h.p. racing car which won the Florio Cup, but of more direct interest to would-be purchasers is the latest touring chassis. This is one of the typical first-class Italian machines, but is in the minority as a type among them by reason of its live-axle—for most Italian cars are chain-driven. Clean design is a characteristic of the chassis as a whole, but there are several small details of especial interest. It has a 4-cylinder engine, on which are an igniter mechanism of peculiar construction, a disc clutch and a four-speed gear-box of the Mercedes type. Both in front and behind the gear-box is a shoe brake, each being operated independently by pedals, and the latter being automatically water-cooled when in action.

Fiat Cars.—Another Italian car represented at the show is the Fiat, but the details of these famous vehicles are so well known to our readers through the special descriptive articles which have appeared on them from time to time (the latest models were described on July 22nd, 1905), that further reference to them now would be superfluous.

Spyker Cars.—Similarly with the new Spyker Car, exhibited by the British Automobile Commerical Syndicate, no mention is needed here because the features of this most interesting "dustless" chassis are described at length elsewhere.

Car Bodies.—Although of secondary importance to the chassis, the body of a car is oftentimes the first consideration of a buyer, and there is no doubt that it is the realisation of this fact which has led to the evolution of such luxurious and convenient carriages as are now standard attributes to every well-appointed stand at an Exhibition. Two such vehicles on the Vinot stall are of special interest. One is a double phaeton, the other a landaulette. Apart from the elaborate completeness of the fittings of the phaeton, it was, as a specimen of body-building, remarkable for the number of different "conversions" of which it is capable. Normally a cosy enclosed carriage, it can easily be changed into an airy limousine by the hinging up of the front window and the removal of the top halves of the carriage doors and sides. In addition to this, however, the entire top is removable so that the car becomes a simple, side-entrance, touring vehicle. Another feature of this car is the arrangement of two folding chairs, which normally lie flat against the back of the front seat. In an instant they can be brought into use, however, and when in position they can be so adjusted that they permit the occupants to face either direction with equal comfort.

On the Vinot landaulette it is the entrance which is remarkable. No seat is provided besides the driver—which offers an admirable excuse for the absence of a footman—the space thus obtained being utilised for the door giving access to the carriage. It is a simple manner of obtaining a really adequate side entrance with a short chassis, and at the same time it detracts nothing from the smart appearance of the vehicle. Its only drawback is that it does not enable the carriage to be entered from the "off" side also.

Motorists who are accustomed to carry their own luggage with them in the tonneau—to the general discomfiture of travellers and kit—will appreciate the simple device which has for some time been a feature of the Spyker cars. It is merely a hinged shelf, formed by part of the panelling at the rear of the car, which can be let down when required. Although not large it will take an ordinary portmanteau, and when not in use it takes up no room nor does it detract from the appearance of the car.

Commercial Vehicles.—Almost the only exhibit of heavy vehicles were those shown by the Thames Engineering Company. On this stall were two petrol-driven chassis and one steam vehicle. The larger petrol chassis is for loads up to 4½ tons and has a 24-30-h.p. engine. One of the characteristic features in the design is the separation of the differential casing from the gear-box. This differential countershaft casing is supported direct by two transverse members of the frame which are specially placed to receive it. Side chains transmit the power to the road-wheels and the gear-box gives three speeds and a reverse. A very large cone-clutch is accommodated in the fly-wheel, and between the gear-box and the differential is a very large shoe-brake. Altogether the chassis has the appearance of being a soundly made machine. Similar general lines have been adopted for the smaller model which is designed for van work with loads up to 1 ton. This, however, has a 2-cylinder engine.

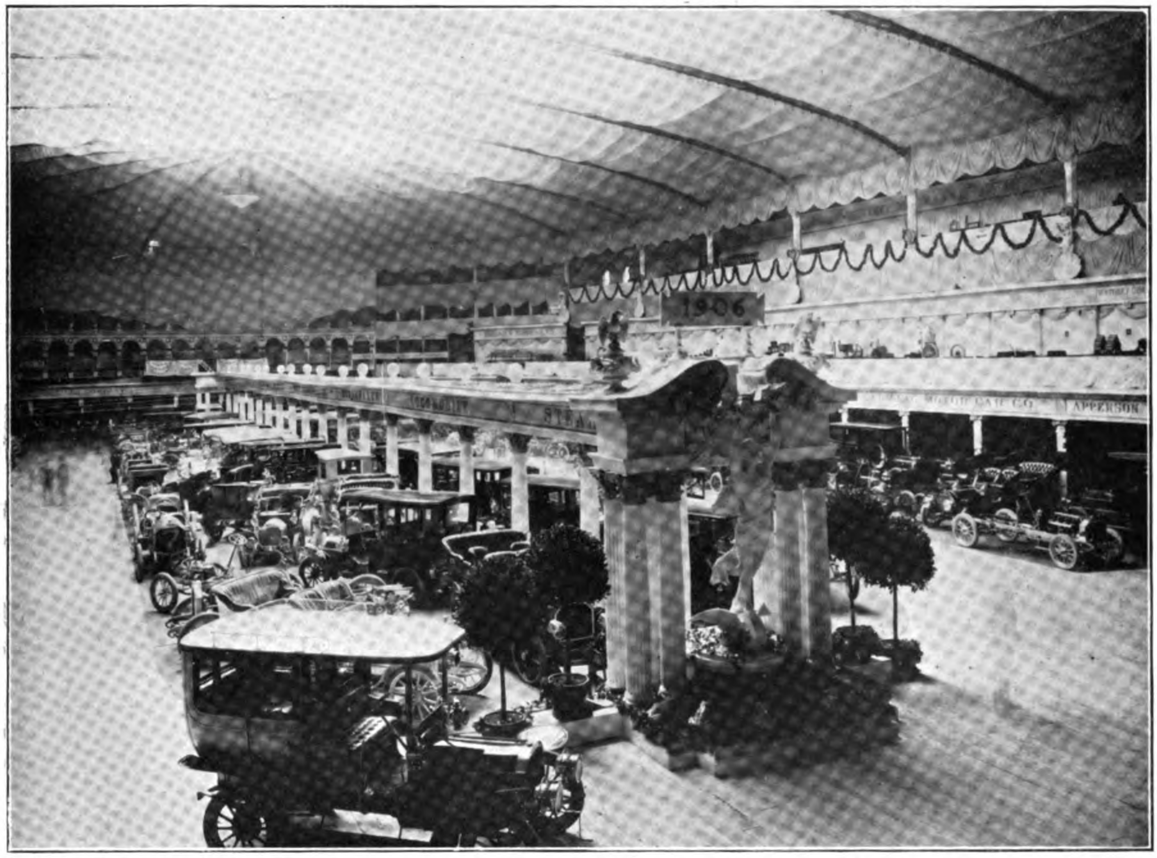
Motor Boats.—One of the principal features at the Palace this year is the motor boat section, and the large lake in the grounds has been requisitioned for the purpose of giving trial runs. There are a fair number of firms in evidence, but nothing of great novelty. Among the most interesting exhibits is that of the Saunders Launch Syndicate, who have tackled the motor boat question with serious earnestness since the beginning. Mr. Saunders' latest idea is the provision of further security against possible leakage of petrol. A strongly brazed tank is carried either fore or aft in the usual way, and a flanged pipe is carried from the tank to the surface of the turtle deck above it. Bolted to this is a special fitting which provides the necessary connections for feed and pressure pipes, indicator gauge and relief cock. Any leakage which occurs at this point must flow overboard, and the only other danger point is the carburettor. There is, of course, nothing very special about the fitting, but it is the carrying out of a common-sense plan of concentrating all the probable sources of leakage at one point, and placing that one point in a relatively safe place.

⊗ ⊗ ⊗ ⊗

THE EDINBURGH SHOW.

A SHOW which opens its doors for the ninth year in succession—each succeeding year's display being a greater success than that which preceded it—can claim to be a fairly well-established institution, and such is the case with the Edinburgh Motor and Cycle Exhibition, held in the Waverley Market, from the 26th January till to-day (Saturday, the 3rd February). There has, however, been something of a change in the character of the show during the passing years, for whereas in its early days it was the Edinburgh Cycle and Motor Exhibition, with a vast display of cycles and a very limited number of motor machines, it is now a motor and cycle show with the cycles generally occupying the small stands under the gallery, keeping the accessories in countenance. A few of the makes of cycles, such as the Sunbeam, Singer and Rover were in the open, but most of the floor area was occupied by cars. Of the latter there was a large variety of both make and quality, and from the man with a Crœsus-like purse to the man of moderate means there was a range of makes and prices suitable for all. There were in all about 120 cars shown, of which from 80 to 90 were of British make. Naturally, the car most largely represented was the Argyll, of which there were 14 located on various stands. Albion came next with 10, Wolseleys 9, Arrol-Johnstons, Swifts and Napiers 5 each, and the 1906 Crossley car, which was shown for the first time. The foreign cars were among the best Continental makes, consisting of Panhards, De Dions, De Dietrichs, Peugeots, Delaunay-Bellevilles, Mercedes, &c. There were 9 Peugeots, 4 Panhards, 3 Delaunays, 3 De Dions, and 2 Mercedes shown. The United States was represented by two Winton machines, and other foreign makes included the Minerva, Gladiator, Regent and Corré. British makes shown in addition to those mentioned were Humber, Siddeley, Brotherhood, Enfield, Daimler, Sunbeam, Singer, Iris, Star, &c. Altogether the most representative show yet held in Edinburgh.

I arrived in Edinburgh early on Saturday morning, determined to be about when the doors opened at 10 o'clock, and have a good look round before the usual Saturday crowd arrived. Well, when I presented myself and my humble shilling at that hour the policeman on duty wasn't having any, and added that he was probably the only man in the Force at that moment unwilling to accept money. The reason given for this truly unprecedented proceeding was two-fold. In the first place the police are not money-takers, and in the second place the show wasn't ready. It appears that potatoes, cabbages, and other edibles have first claim on the market area, and twice or three times during the duration of the show the exhibits have, after closing at night, to be crowded into one end till the market gardeners dispose of the fruits of their industry next morning. After they clear out the motor car stands have to be again fixed up, and the cars themselves returned to position. The incorruptible one thought about 11 o'clock would see everything fixed up, but when I returned about 11.30 his successor thought that another hour would see the show in readiness. What a truly surprising gift of prophecy that man had! By half-past twelve the arrangements were so far advanced as to permit of the admission of the public. But it was pretty rough on the man who got out of bed in the middle of the night to get to Edinburgh by 10 o'clock, and the only advantage resulting from the incident, so far as I can judge, is a proper appreciation of a curious feature of the show placard—the absence of any hour of opening. However, I got in quite soon enough for all there was to see. This statement may seem in strange contrast to the earlier comment above, but it simply means that as most of the cars had been on view elsewhere before there was very little really new. The new Singer car, having a 4-cylinder vertical motor, was exhibited for the first time at any show, and created a very favourable impression. The same firm had on view a new 6-cylinder motor, but nothing was known with respect to their intentions regarding it. A very interesting 6-cylinder engine



The Show of the Association of Licensed Automobile Manufacturers at Madison Square Gardens in New York. This is the show which has been run simultaneously in New York with that of the A.C. of America at the 69th Regiment Armoury, and was organised by the Association of Manufacturers, who are the owners of and upholders of the Selden "master patents." In strong contrast to the rival show at the 69th Armoury, the Association's scheme of decoration, although uniform, was of an elaborate and artistic character, as can be judged by the above photograph; a much more simple scheme was adopted by the A.C. of America.

was shown on the stand of Mr. A. C. Penman, of Dumfries. This machine has been made in the estate workshop of Mr. E. J. Brook, Hoddom Castle, near Ecclefechan. The engine has six cylinders of 2½-in. bore and 3-in. stroke cast separately, the castings, very fine work, being by Willans and Robinson, Rugby. Several special features distinguish this engine, including the speed-control by means of the carburettor, but as they are not yet covered by patents they cannot be described just yet. I hope, however to be in a position to give details shortly. The motor is the work of the engineer employed on the estate, Mr. Ross, and is intended for a small run-about car, on which it will give much pleasanter running than a 2-cylinder engine of 10-h.p. at which it is rated. The new Arrol-Johnston Co. adopted an unusual method of at once giving prominence to the Tourist Trophy winner, and economising space. One of their exhibits being an industrial vehicle chassis with skeleton lurry frame, planks were placed on it from end to end, and the car run up till it rested prominently on the platform thus provided.

A languid sort of interest was manifested in the running of the various cars coming by road from London—the De Dion, the Crossley, and the motor 'bus—but it was confined pretty much to the trade and those connected with it.

I heard some complaint of the want of facilities for trial runs, inquirers about cars, who were taken out for the purpose, being required to pay again on returning to the Show; and I know from experience that, on going out for lunch, I had to pay to get in again, no provision being made by means of pass-out checks for re-admission. This appears to be a mistaken policy, and not likely to help those who are helping to the success of the Show—viz., the exhibitors. After all, they take space for the purpose of selling cars; if they are hampered by such irritating restrictions, it may easily be conceivable that they will seek elsewhere for an outlet for their business energies.

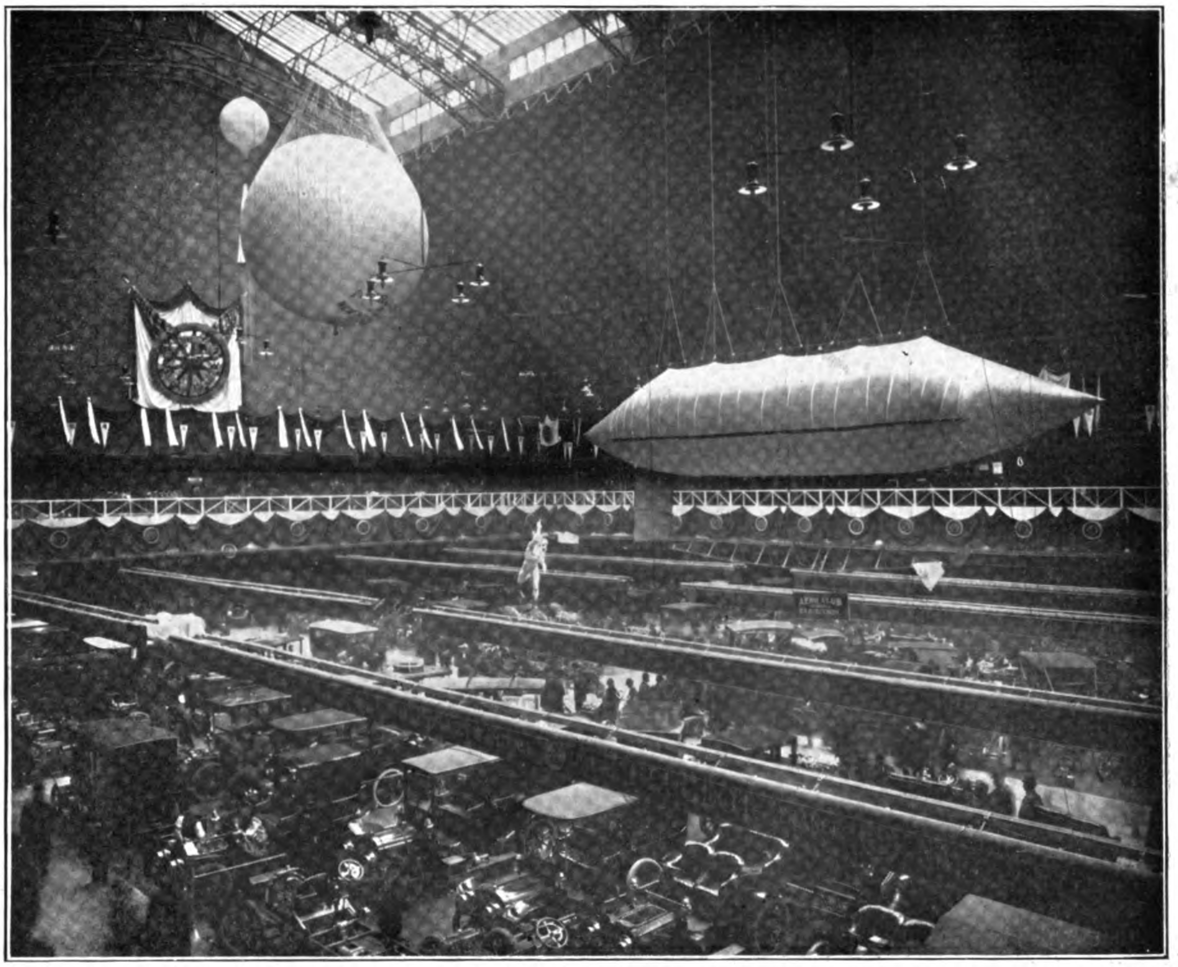
The display of vehicles other than pleasure cars was extremely limited. Besides a new Arrol-Johnston commercial vehicle chassis, suitable for omnibus body or for lurry body carrying loads up to four tons, two heavy steam lurries were exhibited—one by D. Stewart and Co. (1902), Limited, Glasgow; the other by the Glasgow Motor Lurry Company, Limited. Somehow these machines have not caught on in Scotland, and although the lighter petrol lurry is making good progress, the heavy steam machine is at a standstill. I had expected to see a good show of tricars, and, being personally interested in the subject, was somewhat disappointed. There were only five on view—one of them, the only one I should have fancied, a twin-cylinder Singer, being priced at over £150. The others were a Rexette, another Singer of less power, and two others of less consequence. There was a good show of Rex and N.S.U. motor bicycles, and some others scattered singly about the stands.

A. F. S.

* * *

THE MADISON SQUARE SHOW.

THE Sixth Annual Automobile Exhibition, held under the auspices of the Association of Licensed Automobile Manufacturers, opened on Saturday, January 13th. Never has an automobile show been more imposingly staged than was this large collection of cars beneath the roof of the famous Madison Square Gardens. At the entrance was an artistic statue representing the apotheosis of speed; inside, the cars themselves were ranged in orderly array about two wide gangways stretching straight down the length of the building. Individual originality in stands there was none, the staging was a prearranged effect. Down the middle of the main hall ran a line of Roman columns supporting a simple, but well proportioned, cornice, on which the names of the exhibitors beneath were set forth in plain but attractive lettering. Along the top of this cornice was a row of electric lights—powerful but subdued. Similarly arranged at either side were two other lines of columns, and in fact the whole building was decorated on the same modernised Roman lines. Altogether the effect was pleasing to the eye, but it is, of course, quite different to anything we are used to in this country.



The Automobile Exhibition of the A.C. of America in New York at 69th Regiment Armoury. Aeronautical exhibits formed an interesting section of the Show, and a feature, as seen in our photograph, was made of balloons and an airship in the body of the hall. The centre of the hall is marked by the figure of Mercury and the system of plain uniformity in the names of the exhibiting firms, combined with the method of lighting up the signs at night, is a departure in show regulations which, whilst no doubt detracting from the general effect of the Exhibition by the absence of the elaborate stand signs usually displayed, has obvious advantages in its favour.

Of the exhibits themselves there is not much to be said that is of interest to English motorists. Manufacturers in the States are for the most part confining their attention to the perfection of European types, but in the front rank of their respective classes are still those models such as the Winton, Cadillac, and Olds. which have been typical American cars, and have done such credit to their makers in England through the good reputation they established and maintained here. Details of construction vary as much as ever, but the percentage of freak cars steadily diminishes. Ball-bearings for the crank-shaft are in a similar relative minority to their position in this country. Almost the only example is that of the Stevens-Duryea firm, who employ ball-bearings for their 6-cylinder crank-shaft. Lubrication, too, is exercising very general attention, and is obviously being influenced by European practice. Several firms are now discovering the advantages of a simple pump in connection with the ordinary sight-feed fitting on the dash, while others—but they are fewer—are already investigating the possibilities in forced lubrication. Among the novelties, one of the most interesting is the pneumatic installation on the Northern car for working the clutch and the brakes. Driven by the engine is a small compressor capable of supplying air at 75 lbs per sq. inch. For operating the clutch the air is pumped through the hollow crank-shaft so that it acts on a leather-faced diaphragm, which it forces into contact with a corresponding disc on the driven shaft. This same firm have ingeniously converted the gear-wheels driving the cam-shaft into a circulating pump by enclosing them in a water-tight case; while another striking departure on the same vehicle is a ratchet-lever starting-gear instead of the familiar crank-handle.

Not unnaturally, perhaps, the ignition system has undergone a most marked change during the past year. Previously the magneto in any form was hardly in evidence, now it seems to have come to stay, although just at the present time there is no decided preference for either the low or the high-tension systems. Although hardly ever used in this country, it is well known that many American cars fit dry batteries instead of accumulators, and their merits, when used in connection with the magneto, are undoubtedly deserving of general attention. Unlike the accumulator, they are not so liable to deteriorate when idle, and, consequently, when only required for starting the engine, and as an occasional substitute for the magneto, their long life should render them, on the whole, economical.

THE A.C. OF AMERICA AUTOMOBILE SHOW.

In opposition to the Madison Square Exhibition, the A.C. of America held a Show in the Armoury of the 69th Regiment, which was patronised by a large collection of exhibitors, who were not enrolled under the banner of the Association controlling the Selden Patents. Among well known cars exhibited at the Show were the C.G.V., Daimler, Duryea, Ford, Mercedes, Mors, Napier, and White, but naturally the details of these did not differ from those already shown in this country. Among the other exhibits there was little of special interest, although the same tendencies in design as were evident at the other Show were, of course, to be noticed at this Exhibition also.

RACES, RECORDS, AND TRIALS.

Ormond-Daytona Race Meeting.

THIS year's racing on Daytona Beach has brought down several world's records to what would appear to be nearing finality in speed. The extraordinary performances of the Stanley steam car, which we mentioned last week, have been further added to, whilst a splendid victory has been achieved by the British-built 6-cylinder Napier in the 100 miles race. The nature of the beach course suggests the possibility of phenomenal speeds, but the very thought of a mile in 28⅕ secs. (equal to 127·65 miles per hour) makes one's breath come a good deal quicker. Clifford Earp's performance of 100 miles in 75m. 40⅗s., is, of course, a much more wonderful feat, owing to the continued strain entailed by driving at such a nerve-racking speed. The famous Darracq cars have also done well, although they have been driven under such serious handicap, owing to Hemery, the Darracq official driver, having fallen foul of the authorities and being disqualified. It appears that a false start was made in a 5 mile race in which Hemery was running against Stanley. Hemery, however, had got away, not knowing this, and covered the course, it is stated, in 2m. 34⅕s., and when told it was "off," he flatly refused to recognise any such decision and was in the end disqualified from further driving at the meeting. Arrangements were, therefore, made subsequently whereby Guy Vaughan and Chevrolet took over the wheels of the Darracq cars for the rest of the races.

Bad weather during the week necessitated a postponement of some of the races, so that the meeting extended into this week.

Stanley is reported to have undertaken to deliver by June next, to Mr. W. Gould Brokaw, the American millionaire, a steam car capable of covering 1 mile in 25 secs.!

The following are the chief results of the meeting:—

In the one mile race for the Dewar Cup, the Stanley steam car was the winner, in 33s., against Cedrino in a Fiat, in 38s.

Lancia, on a Fiat, secured the mile race for heavy petrol cars with 37s.

Stanley subsequently lowered his own record for the mile to 31⅗s.

Five Miles Open Race.—1. Lancia (Fiat), 3m. 1⅕s.; 2. Fletcher (Fiat), 3m. 2s.; 3. Stanley, 3m. 3s. In the heats Stanley made 2m. 47⅕s.

Five Miles—Heavy Petrol Cars.—1. Clifford Earp (Napier), 2m. 56s.; 2. Downey (Mercedes), 3m. 29⅕s.

Five Miles—Middle-weight Cars.—1. Cedrino (Fiat), 3m. 53⅗s.; 2. Holmes (Wayne), 5m. 46s.

Corinthian Race (Ten Miles).—1. Vaughan (80-h.p. Darracq), 9m. 28s.; 2. Breeze (60-h.p. Mercedes), 9m. 47⅗s. Darracq time during heats, 6m. 36⅗s.

Ten Miles—Middle-weight Cars.—1. Vaughan (80-h.p. Darracq), 7m. 2s.; 2. Cedrino (Fiat), 7m. 50s.

Flying Kilometre.—1. Marriott (Stanley steamer), 18⅖s.; 2. Chevrolet (Darracq) 19⅗s.; 3. Earp (Napier), 21⅗s.; 4. Cedrino (Fiat), 22⅕s.; 5. Kulick (Ford car), 24⅘s.

Flying mile (steam vehicles).—1. Stanley, 28⅕s. = 127·65 miles (205·43 kil.) per hour.

Flying mile (petrol cars).—1. Lancia (Fiat), 37s.; 2. Fletcher (Fiat), 37⅗s.; 3. Cedrino (Fiat), 38s.; 4. Earp (Napier), 40s.

Flying mile (heavy cars).—1. Chevrolet (Darracq), 30⅗s.; 2. Cedrino (Fiat), 36⅗s.; 3. Earp (Napier), 37⅘s.

10 miles Cornellian handicap (for amateur drivers).—1. H. N. Harding (45-h.p. Daimler), 8m. 48⅗s. (handicap 3½m.); 2. Stevens (80-h.p. Darracq), 6m. 42⅘s. (scratch).

100 miles (standing start) International Championship (Minneapolis Cup)—1. Earp (Napier), 75m. 40⅗s.; 2. Cedrino (Fiat), 76m. 39s.; 3. Hilliard (Napier), 81m. 5s. During this race, after the 35th mile, Earp shed a tyre, but took practically little notice of the mishap, simply pounding away in marvellous style and finishing winner in the magnificent record time as above—Cedrino, who stopped to repair a tyre, also drove grandly, securing second place.

Fifteen Miles.—1. Lancia (Fiat), 10m.; 2. Hilliard (Napier), 11m. 36⅗s.

Ten Miles.—1. Lancia (Fiat), 6m. 19⅖s.; 2. Marriott (Stanley), 7m. 35⅗s.

Thirty Miles, open to American cars only.—1. Marriott (Stanley), 34m. 18⅖s.; 2. Chevrolet (Christie), 37m. 24⅗s. In this race the Stanley car was delayed 5m. 40s. at the start, but even then managed to make the best time, as above.

"Two Miles to the Minute Race."—1. Demogeot (Darracq), 1m. 1⅗s.; 2. Marriott (Stanley), 1m. 3s.

In a later race these two cars are reported to have made the following extraordinary times for the two miles:—1. Demogeot (Hemery's mechanician), 58⅘s.; 2. Marriott, 59⅗s.

An objection was lodged, at the end of last week, by Lancia against the Darracq cars, as they were not fitted with reversing gear. This objection appears to have

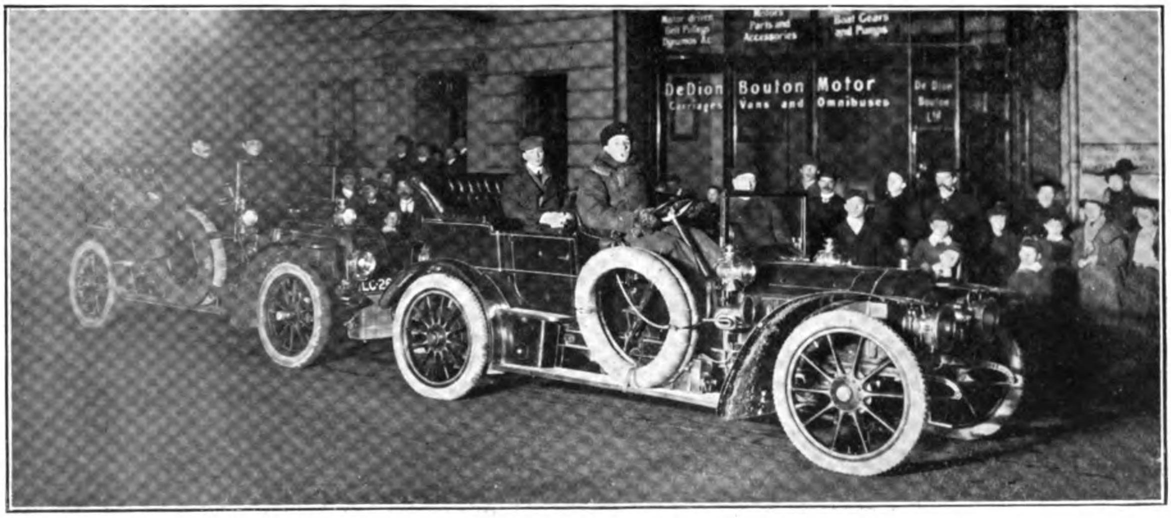


Photo by Argent Archer.

LONDON TO EDINBURGH IN ONE STAGE.—A flashlight photo of Mr. Charles Jarrott on his Crossley Car, and Mr. J. W. Stocks on his De Dion prior to the start for their "non-stop-engine" journey, on Friday night last week, from the London General Post Office to the Edinburgh Motor Exhibition.

been upheld, with the consequence that, on Monday, they were not permitted to run officially in any event over one mile in length. The conclusion of the meeting was finished in splendid weather on Monday of this week.

Tourist Trophy Race.

IT has been officially settled that the race for the Tourist Trophy this year will take take place on Thursday, 27th September, in the Isle of Man.

100-Guinea Cup for Tourist Trophy Race, 1906.

THE Continental Tyre Company announce their intention to again present a 100-guinea trophy (or cash if desired) in connection with this year's race, in the event of the winning car being fitted with their tyres. In the last year's race, it will be remembered, this trophy was secured by the winning Arrol-Johnston car, which so successfully employed these tyres.

Tyre, Lamp and Speedometer Trials—Change of Date.

THE A.C.G.B.I., acting on a suggestion made at a conference with the representatives of the tyre manufacturers on January 25th, has decided that the Tyre Trials —and with them the Lamp, Speedometer and Car Trials —shall begin on Monday, February 26th, 1906, and that entries shall be accepted up to noon on Monday, February 12th, 1906. Sufficient support has already been promised to make the holding of these Trials a certainty, and though one or two of the big firms have not as yet signified their intention to enter, it is thought that they will practically all do so. The regulations, which have already been published in THE AUTOMOTOR JOURNAL, provide for practically all classes of tyres.

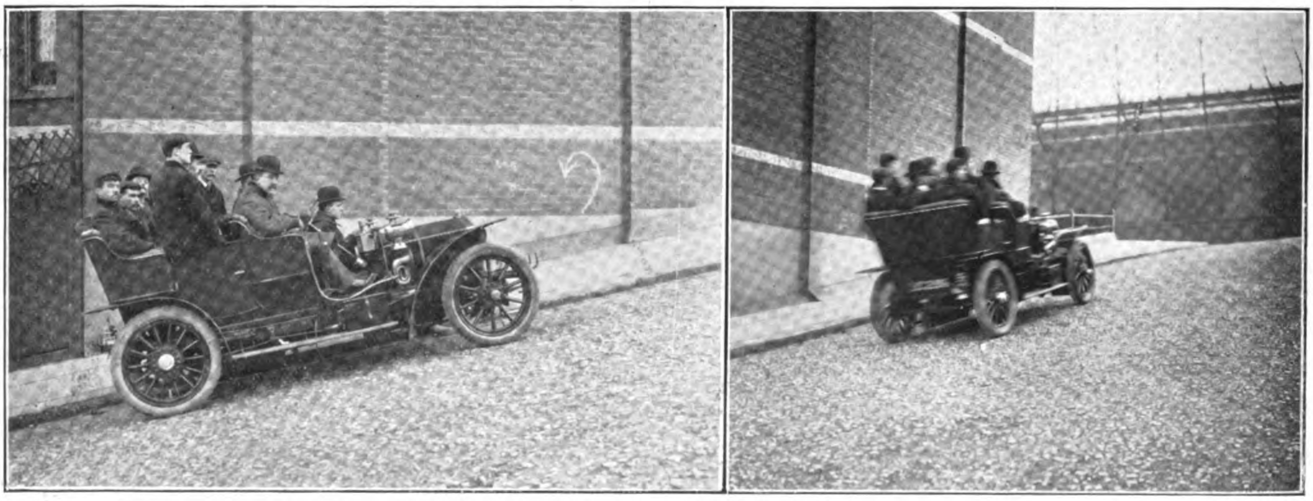
London to Edinburgh.

A STRAIGHT-THROUGH run between these two cities is not the pleasantest, nor the easiest, experience to have of motoring, especially in the winter. During last week, however, no less than three motor vehicles accomplished this self-imposed task. Of these, one was Mr. Chas. Jarrott's 22-h.p. Crossley, another was Mr. J. W. Stocks' 24-h.p. De Dion, and the third was a Fiat 'bus with a "party" of thirteen on board, under the guidance of Mr. Victor Miller. Leaving the G.P.O. at 9 o'clock on Friday night, the 26th inst., Messrs. Jarrott and Stocks, driving their respective cars, set out on their 400 miles' journey. Mr. Stocks acted as pilot, but even in spite of his very thorough knowledge of the route, he once lost his way after leaving Selby. This caused some little delay, but it was nothing of consequence, and the cars kept steadily together all the way to Berwick. Here Mr. Jarrott encountered the customary dog, and only saved an accident by jamming on the brakes with such violence that he deranged the gear, and had to remain behind for a while to put things right again. On this account the Crossley car did not arrive in Edinburgh until 5.30 p.m. Saturday, which was half an hour after the schedule time based on an allowance of 20 hours for the journey. Mr. Stocks arrived within the limit, both having accomplished their object of "engine non-stop" runs. The Fiat 'bus, which had started earlier in the day on Friday, was also in evidence about the same time, having travelled up in 32 hours.

Additional lustre was added to the run by Mr. Jarrott's subsequent adventurous drive up Arthur's Seat with the Crossley car, carrying Mr. Letts, a couple of journalists, a photographer, and a mechanician. With this considerable load Mr. Jarrott surmounted the sharp turns and difficulties of the ascent in fine style, and may, we believe, claim to have been the first pioneer who has ever ascended the celebrated eminence with a fully laden automobile.

5,000 Miles Humber Trial.

ON Saturday last, the 27th inst., Mr. R. M. Wright, of Lincoln, concluded a run of over 5,000 miles on a 10–12-h.p. 4-cylinder Humber car. It was a sporting trial, organised and carried out entirely by Mr. Wright, who was anxious to show the people of Lincolnshire what could be done with a British-built car of moderate power, for which, among others, he has an agency in that county. Local residents were enrolled as observers, among them being such well-known motorists as Messrs. W. B.



PREPARING FOR THE TOURIST TROPHY RACE.—A rule which has been instituted by the A.C.G.B.I. in connection with the T. T. race this year, provides that each car with its full load must be able to ascend a grade of 1 in 6 on its lowest gear and must be capable of travelling half a mile on the flat on the top gear without clutch manipulation at a speed of not more than 12 miles per hour. Recently the Rolls-Royce Tourist Trophy car of last year has undergone a series of tests under these conditions, when both these requirements of the rule were more than complied with. Our photographs show the car "at rest" upon, and actually ascending a gradient of 1 in 6·09, not only with the specified minimum weight (equal to four passengers) but with nine passengers averaging 11st. 2lbs. each.

Jevons (the first motorist in Lincoln), A. A. Padley, W. S. Foster, W. Foggo, M.I.M.E., J. R. Hatfield, W. Rasdall, and J. T. Coleman (Chief Constable of Lincoln).

The following is a summary of the running costs as published by the organiser of the trial:—

					£	s.	d.
Petrol	... ...	262 gals.	at 1s.	=	13	1	9
Oil ...	... ...	18 gals.	at 5s.	=	4	10	0
Grease	... ...	28 lbs.	at 6d.	=	0	14	0
Gear Oil	... ...	1 gal.	at 3s. 6d.	=	0	3	6
Accumulators	...	11 recharges	at 9d.	=	0	8	3
Commutator	...	Ring replaced		=	0	3	6
		Total for 5,000 miles		...	19	1	0

Running cost per mile = 0·915*d*.

In addition to this it is estimated that a sum of about ¾*d*. per mile should be allowed for tyre depreciation, which would permit retreading each cover at a cost of £3 12*s*. each.

The total involuntary stops for the car amounted to 49 mins., and for the tyres 2 hrs. 13 mins. for five punctures. The trial occupied over 41 successive days, the observers choosing the routes. Rain fell heavily on 11 days, and the roads were only dry on 5 days.

At the conclusion of the run on Saturday, the Humber Company and the Dunlop Tyre Company—the respective manufacturers of the car and tyres—jointly gave a luncheon to Mr. Wright at the Crystal Palace. Mr. E. Powell, chairman of the Humber Company, occupied the chair, and among those present were Messrs. W. B. Jevons, A. A. Padley, T. C. Pullinger, W. Phillips, W. J. Greer, J. Mason, L. Coatalen, and L. M. Bergin. While this pleasant function was in progress, the car was dismantled so that the parts were afterwards available for inspection. So far as could be seen, everything was in excellent condition. There were signs of there having been, at some time or other, a lack of oil on one of the big ends, and of the second speed having been injudiciously engaged occasionally, but otherwise no signs of undue wear could be seen on any of the parts.

The Grand Prix.

Santos Dumont will possibly be a starter in this race, with a car fitted with a Levasseur motor, with between 16 and 24 cylinders, developing anything up to 300 h.p. The date mentioned for the race is June 25th and 27th.

Gradual Variable Speed-Gear Contest.

A competition is to be organised in France by *Les Sports*, acting in conjunction with M. Ernest Archdeacon, for variable speed-gears.

Calcutta-Ranchi Motor Trials.

The Automobile Association of Bengal announce that, owing to the paucity of entries received, they were compelled to indefinitely postpone the holding of the proposed Trials on the 26th January and following days.

Western India Trials.

We learn that two Argyll cars have been successful in the four days' reliability trial organised by the Motor Union of Western India. The trial was over a distance of 500 miles. In class B (cars £250 to £450), the 10-12-h.p. car has secured two Cups, and in class C the 16-20-h.p. car wins the Challenge Shield and a Challenge Cup. These were the only Argyll cars entered.

Circuit Européen.

By degrees the detailed arrangements are shaping themselves for this important motoring event for 1906. The general outline for the route and the dates have been agreed upon, allowing for 15 days running and 6 exhibitions at the principal centres traversed. The suggested route is as follows:—

July 29—Paris-Limoges.
,, 30—Limoges-Toulouse.
,, 31—Exhibition at Toulouse.
Aug. 1—Toulouse-Le Puy.
,, 2—Le Puy-Aix-les-Bains.
,, 3—Exhibition at Aix-les-Bains.
,, 4—Aix-les-Bains-Milan.
,, 5—Exhibition at Milan.
,, 6—Milan-Trieste.
,, 7—Trieste-Klagenfurth.
Aug. 8—Klagenfurth-Vienna.
,, 9—Exhibition at Vienna.
,, 10—Vienna-Prague.
,, 11—Prague-Breslau.
,, 12—Breslau-Berlin.
,, 13—Exhibition at Berlin.
,, 14—Berlin-Hanover.
,, 15—Hanover-Cologne.
,, 16—Exhibition at Cologne.
,, 17—Cologne-Mézières.
,, 18—Mézières-Paris.

Cars are to be penalised by one point per minute during breakdowns, except for tyre troubles. These points will be added to the time points allowed under the rules to each class for the total time occupied throughout the run. Time occupied in tyre troubles will count against a competitor, in the event of such time not being made up again in each day's run under the maximum time allowance—which provides for one point per minute penalisation for any excess of time beyond the maximum allowed to each class.

It is proposed to limit the total number of entries to 130—so that late entrants may find themselves "out of the running." Each of the recognised clubs will receive entries for their country—entries until April 15 will be at single fees, after that date at double fees. The club of each country will be responsible for looking after the roads selected for the contest, in regard to flagging and maintaining order and providing protection against possible accidents at congested points, &c. The official documents will be in French. Diplomas will be given to every competitor completing the full itinerary, in the joint names of the Automobile Clubs of France, Germany, Austria and Belgium. Already a number of the leading Continental makers have signified their intention to enter cars, and altogether there is little doubt the event will prove to be, from a commercial point of view, one of the most important contests hitherto organised.

* * *

MOTOR CYCLING.

International Cup for Motor Cycles.

It looks as if the motor cycle "Little Gordon-Bennett" contest of the Moto Club de France is to be squeezed out of existence, now the Cup has been won by Austria and taken out of France, in similar fashion to the attempt on the Gordon-Bennett Race for cars. It is with difficulty that a French maker has been found to enter for this year's contest. Neither Alcyon, Peugeot, or Griffon machines are to be run, and the only house to enter is the Gillet, the makers of which are to have three machines in line.

A New Motor Cycle Cup.

Following the meeting when this decision was arrived at, a cut and dried announcement of a new "Championnat International de Motocyclettes" was sprung upon the motoring world by the Moto Club de France. This is to take place in May, and there will be three categories, viz.:—(1) for motor bicycles under 30 kilogs. weight; (2) under 50 kilogs.; and (3) 2-seated motor cycles, with three or four wheels, under 250 kilogs. If, however, this new contest is so arranged that it promotes the use of *bona fide* touring machines, there need not be much outcry at the absence of the "crack" French motor cycles from the International Cup, as the new race should tend to help along the touring machine industry considerably.

AERONAUTICS.

"And Thick and Fast They Came at Last."

We mentioned last week the experiments of a Danish aeronaut with a motor-driven aeroplane, and now it would appear that quite a number of people (who hope to attract attention or win the Deutsch Prize with machines of the aeroplane type) are appearing upon the scene. Chief amongst these apparently is the Polish aeronaut, Mr. Godek, who has arrived in Paris, we are informed, in order to make trial trips with his aeroplane *before* competing for the Deutsch-Archdeacon Prize. Why Mr. Godek should regard Paris as a good place to experiment in or near is something of a mystery. As an example of the sort of statements finding currency on the subject it is claimed for his machine that the aeronaut operating it can take any position, "unlike the Wright aeroplane, which requires the operator to lie down." Surely it should be obvious that the question of lying down or standing up is merely a matter of wind-resistance and the reserve force available in the aeroplane, together perhaps with the comfort of the operator. Possibly, too, the feeling of security may have something to do with it. Anyone who has looked over the edge of a lofty cliff knows how very much safer he feels if he lies down to do so.

A "Léger" Machine.

Another competitor is announced in the person of M. Léger, engineer to the Prince of Monaco, who is understood to be adopting a machine of the "helicoptere" type. The Léger machine is said to have two vertically-lifting propellers, one above the other, revolving in different directions, and a tractive propeller in front. A mysterious particular announced in regard to the propulsion of the machine is that it is stated to be driven by two dynamos exercising a power of 10-h.p. This is not a very likely departure at the present day.

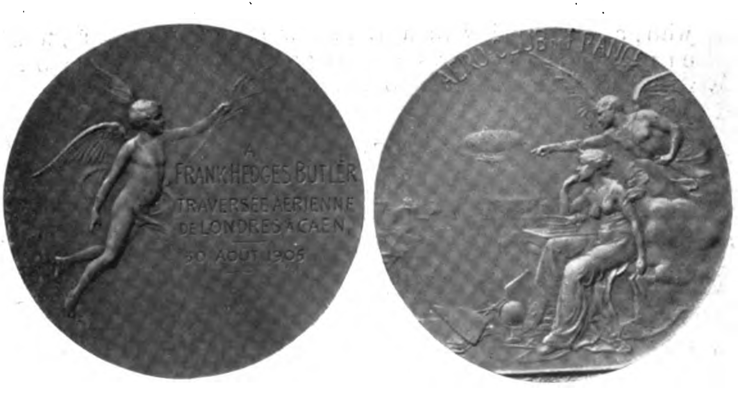
Other French Experimenters.

Two inventors of the name of Martzoff and Vuina are carrying on a number of experiments with what is said to be a new type of aeroplane in the neighbourhood of Mostesson. The aeroplane is mounted upon the framework of a quadricycle, and pulled forward by a tractive propeller. The tractive effort of the propeller driven by a 25-h.p. motor is effective in propelling the whole system along the road. The inventors hope, ultimately, to be able to attain sufficient speed to enable the aeroplane to rise in the air. Hitherto the speed attained has not been as great as was anticipated, but as the speed of rotation has been relatively small, it is expected that this condition of affairs will be improved at an early date.

Retirement of Count Zeppelin.

The rumour that, as a result of the failure of his great effort, Count Zeppelin has determined to definitely retire from aeronautics is now confirmed. Most people will feel a pang of regret at this final confession of failure on the part of the venerable and enthusiastic experimenter.

Though, owing mainly to the unsuitable dimensions of his apparatus and the inappropriate shape of his gas-vessel, great exploits were hardly to be expected from even the last Zeppelin airship, the circumstances which largely destroyed it were after all, it must be remembered, in the main accidental. It is generally understood that the catastrophe was due to the derangement of longitudinal stability in such a manner as to cause one end of the airship to come into violent contact with a tree. Had the result not been so disabling to the airship, no doubt longitudinal stability would soon have been attainable, though that any effective speed would ever have been obtained with the Zeppelin airship is almost more than doubtful. When all is said, however, it must be recollected that Count Zeppelin is an enthusiast of the best type. He has sacrificed his own fortune in his experiments, he was the second in the history of aeronautics to really direct and manœuvre a navigable balloon, and his experiments with aerial propellers, both on balloons and boats, has had a decided effect in advancing knowledge in regard to the actual propulsive effort that could be attained by this means. It is probably only Count Zeppelin's advanced age that decides him on retiring from his field of investigation, for after all the two accidents which he has had were no more damaging than each of those which overwhelmed the Lebaudy airship in the moments of its greatest triumphs. If the engineers and capitalists engaged in that great "emprise" had retired after two misfortunes, they would never have attained success. But, after all, one must retire some time, and Count Zeppelin has unquestionably done good work in the department of research to which he devoted his fortune, and a long period of his life.



Mr. Frank H. Butler is one of the best known supporters of aeronautical projects, and personally takes a great practical interest in the development of everything pertaining to aeronautics. We some months ago published a photograph of his "pilot" certificate, issued by the Aero Club of France, and he has now been further honoured by the same body, by the grant of a medal to commemorate the longest cross-Channel trip. This is the first one ever granted by them to an Englishman, and was awarded to Mr. Butler and Mr. Percival Spencer. We produce this beautiful medal above, on one side of which is engraved the record of Mr. Butler's performance, in the following words:—"A Frank Hedges Butler Traversée Aérienne de Londres à Caen. 30 Aout 1905."

The late Mr. Stanley Spencer.

The death of Mr. Stanley Spencer is announced from Malta. He was returning home from Calcutta when he fell a victim to an attack of typhoid fever, which became so serious that he was disembarked at Malta, at which place he subsequently succumbed to the fever. Mr. Spencer, as most people know, was a partner of his two brothers in the well-known Highbury firm of balloon-makers. He has always taken a great interest in aeronautical matters, and in 1903 constructed the "Mellin" airship, with which he passed over London. Mr. Spencer has made balloon ascents and parachute descents with much intrepidity in nearly all the principal countries of the world, so that to die of a commonplace disorder like typhoid fever is a rather unexpected termination to so adventurous a life, and one in which he had so often executed daring and dangerous exploits.

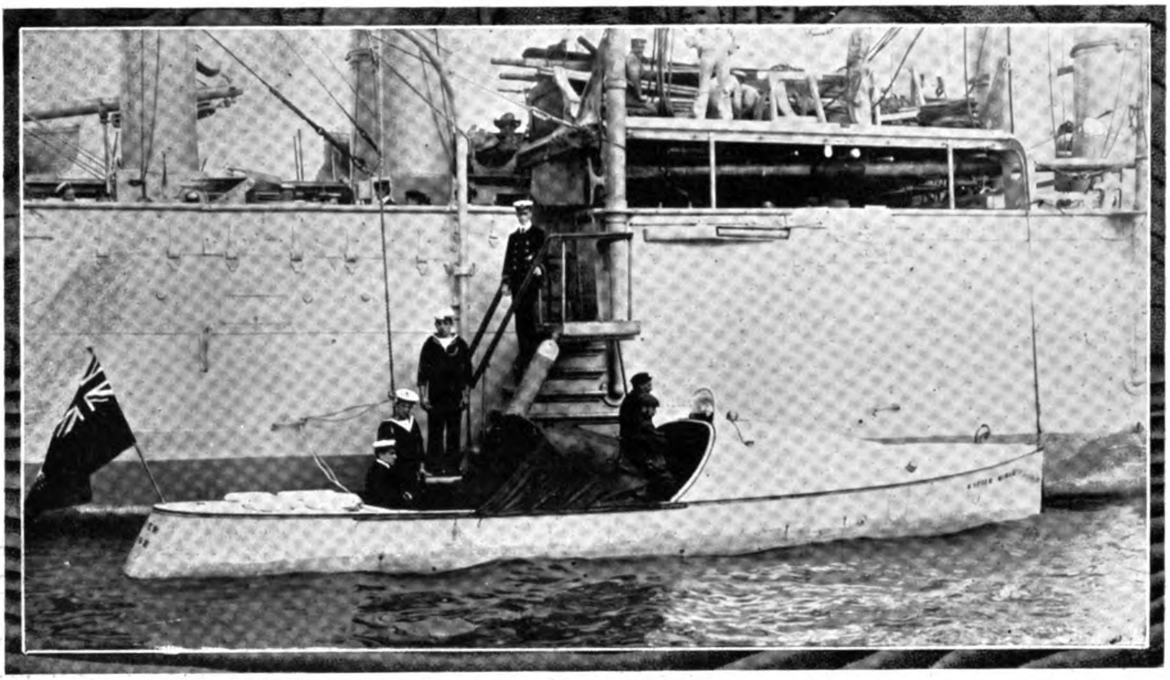
Not in Keeping with the Times.

It is somewhat disconcerting to find the Engineering Supplement of *The Times* reproducing the letter of Mr. Roe which we published last week, with the following editorial comment—the italics are ours. Says *The Times Supplement*:—

> "Whilst giving that encouragement to new enterprise denoted by the admission of what is patently a free advertisement to our literary columns, it is not to be supposed that we in any way adopt the writer's estimate of his undertaking, *being of the opinion, indeed, that all attempts at artificial aviation on the basis he* describes are not only *dangerous to human life, but foredoomed to failure from an engineering standpoint.*"

Prophecy has been generally admitted to be one of the most gratuitous errors which one can commit. It is bad enough to prophesy as regards the far distant future, and in regard to subjects so deeply wrapped in the mysteries of the "far-off," that no one living will have a chance of ascertaining whether the prophecy is destined to be fulfilled or not. It is more than usually gratuitous to prophesy or maintain the impossibility of what has already been done. Unhappily, this is just the view of the man in the street. It is not calculated to promote research, or what is of, perhaps, more importance, provision of funds for the purpose of research. That *The Times Engineering Supplement* should take this old-fashioned view, contraverted as it is by innumerable facts, is distinctly disheartening.

* * * *



During the 1904 season, the Admiralty were already coquetting with the motor boat in connection with the naval manœuvres. Our picture is an interesting little souvenir of this fact and represents Napier Minor, which was placed by Mr. S. F. Edge at the disposal of the Admiralty, alongside the second-class cruiser, Apollo. The photograph is by Mr. A. F. Evans, who was enabled to get this snap from a steam cutter placed at his disposal by the captain of the Apollo.

Major Lindsay Lloyd, R.E.

Owing to ill-health, we regret to learn that Major Lloyd has been reluctantly compelled to relinquish the post of President of the Marine Motor Association.

Where the Fire Engine Failed.

Messrs. Bowley and Sons' works were successful in "setting the Thames on fire" on Saturday morning last, and provided a brilliant pyrotechnical display for those who happened to be about Battersea at the time. Great floods of burning petrol and other oils "brightened" the surface of the Thames, and did a good deal of destruction to barges in the river. The proceedings of the fire floats, however, were calculated to raise a smile. How it could be supposed that burning oil floating on water was to be extinguished by pumping more water on it, is one of those mysteries of the official mind which ordinary people are unable to fathom. One is reminded of the suggestion, sarcastically attributed by *Punch* to a medical paper, that ice having been found frequently contaminated with microbes, it should never be used without having previously been boiled!

AUTOMOBILE ASSOCIATION CIGARS
WITH A MATCH FOR PERJURERS

AUTOMOBILE ASSOCIATION ANNUAL DINNER.—The clever menu card which was specially designed for the Association's Dinner last week happily hits off many of the little weaknesses of certain sections of the police in connection with their treatment of motorists.

Automobile Association.

Very enjoyable was the first annual dinner of the Automobile Association at the Trocadero last week. Under the genial chairmanship of Col. W. J. Bosworth the gathering was notable for its short toast list and its unprecedented list of popular entertainers. Altogether there were some 180 diners present, and as an assemblage of victims (or their sympathisers) of police—pardon, motor traps—the evident enjoyment of the guests would have made the Surrey and other police trappists pale with rage. The menu, which we reproduce in facsimile, was a cleverly-conceived skit upon the questionable tactics of certain sections of the police, and graphically drew attention to the neglect of their proper duties.

In a quaintly facetious and highly amusing speech, Mr. Mostyn Pigott proposed the toast of the Association. He said that he was not the owner of a car, and that if anybody bequeathed him one in his will he would be prompted to murmur, "Some enemy hath done this thing," because he would not know where to put the implement in question. To a certain extent he thought the Automobile Association rendered existence almost bearable to the impecunious pedestrian. Said Mr. Pigott, "As a private citizen I need protection. By protection, I mean protection from the dare-devil begoggled fellows who drive motor cars to the infinite peril of myself, my family, my hens and chickens, if I have any, or my neighbours' if I havn't. The law doesn't afford me this protection, nor do the police. Legal compensation for injuries is all very well, but it isn't protection. I prefer the protection, and am content to let the other fellow have both the injuries and the redress. That is where, as a private citizen who has not the privilege of owning a motor car, I look to the Automobile Association for protection, and find it. While the police are hiding behind hedges and lurking in ditches waiting for the fellow I'm afraid of, to break the law, the Automobile Association sends out its yellow badged scouts and prevents him breaking it. That is what I call protection."

Col. Bosworth, in responding, said that motorists had taken their persecution too long lying down, hence the formation of the Association. All members asked for was equal rights with other users of the highway—they asked no more. The Association had no sympathy with the motor hooligan any more than with the hooligan van or carriage driver. He was glad to say the friction between motorists and the police was now gradually subsiding. He had actually seen one of their members driving home the "components of a police trap" in his car after their day's work. He hoped the day was forthcoming when the police-trap constables would say: "Marcellus and Bernardo, break we our watch up."

Sir Archibald Macdonald, who also replied to the toast, spoke in flattering terms of the splendid work done by the chairman. The only reason for van drivers invariably driving on the wrong side of the road was, he thought, that they found it more to their liking going to sleep on the right side.

Lt.-Col. Mark Mayhew proposed "The Visitors," Mr. Sidney Straker replying; and Mr. Charles Jarrott, in giving the toast of "The Press," passed a well-merited compliment upon the particularly energetic and unflagging methods of Mr. Stenson Cooke, the secretary of the Association.

Amongst those who supported the chair were:—Sir A. Macdonald, Bart., Col Mark Mayhew, the Chevalier Distin Maddick, Baron A. Turckheim, Messrs. Sidney Straker, Mostyn Pigott, Charles Jarrott, Chas. Temperley, A. Harris, L. Schlentheim, Wm. Letts, Walter Gibbons, Capt. Leveson-Searth, Messrs. Stanley Spooner, Andrew McKelvie, B. C. Cass, F. Thring Robertson, H. W. Staner, C. L. Freeston, S. Byng Maddick, C. Cordingley, De Courcy Beamish, J. R. Cleave, A. Pelland, J. Barry O'Callaghan, H. Barnett, W. Willett, Turcat-Mèry, H. E. Harrison, J. P. Waddington, F. Glenister, C. P. Bennett, J. Ferguson, E. Baker, J. Duffy, R. O. Bryen, F. Newson-Smith, F. W. Dewdney, F. W. Lord, H. Newson-Smith, W. Worby Beaumont, A. Davies, J. Temperley, L. Brennan, C.B., Rocco Gatti, A. J. Wilson, J. W. Stocks, C. Pinoli, F. F. Wellington, E. H. Lancaster, R. Noble, J. D. Willis, A. Hoboken, J. A. Parkes, W. J. Peall, Dr. Stillwell, Mr. R. D'Arcy Baker, Capt. de Fasge, Dr. Jackson Lang, Messrs. Graham Notley, W. Wyatt, F. M. Trevor, M. E. Schlentheim, J. S. Purdie, E. E. Robb, R. I. Atkinson, L. Martin, J. S. Gibson, H. A. Matear, H. Tanner, Chas. Heathcote, D. W. McInnes, Dr. D'Esterre, Messrs. E. Heathcote, W. R Brooke, L. Langford, Major Woodley, Messrs. J. Finlay, C. H. Steam, A. J. McCarthy, W. Rees Jeffreys, F. T. Woodfine, F. Straight, S. Hyman, E. Aplin, F. Elliott, H. Sutton, Ben Nathan, Arthur Roberts, H. Masters, M. Warner, W. de Freece, H. Milburn, E. Romaine, &c.

The Aero Club.

THE Aero Club has recently purchased a special balloon for the use of its members. This balloon, built on up-to-date principles, is fitted with new type of valve, rip cord, and all the latest improvements, and will accommodate four to five persons, according to the length of the journey. Members can hire this balloon for two guineas a time, and special facilities have been made by the club for its quick inflation, &c.

The following have been elected to the club committee of 1906:—The Right Hon. Lord Howard de Walden, the Right. Hon. Lord Montagu of Beaulieu, the Hon. C. S. Rolls, Maj.-Gen. Sir H. E. Colvile, K.C.M.G., C.B., Rear-Admiral Sir Charles Campbell, K.C.M.G., C.B., Col. J. E. Capper, C.B., R.E. (Director of Military Ballooning), Professor A. K. Huntington, Dr. F. W. H. Hutchinson, Messrs. Roger W. Wallace, K.C. (chairman), C. F. Pollock, Hugh Weguelin, Frank Butler, A. Leslie Bucknall, Martin Dale, Stanley Spooner.

British Empire Motor Trades' Alliance.

THE Daimler Motor Company have sent £20 to the Alliance towards their Foundation Fund, this being the company's second donation to this fund.

British Motor Boat Club.

THE second lecture of the club will be held in the club room at the Craven Hotel, on February 15th, at 8 p.m. The paper will be given by Lieut. Windham, R.N., and will deal chiefly with matters relating to petrol and paraffin engines as fitted to motor boats, the markings on charts, laying out courses on charts, lights at sea, handling motor boats in rough seas. The paper will be followed by about sixty lantern slides on lifeboat work in Ireland, the slides being shown for the first time. There will also be about sixty slides on various motor subjects. The secretary will be pleased to receive, on loan for the evening, any slides interesting to motor boat owners. An informal dinner will precede the lecture.

Motor Union.

THE General Committee of the Motor Union of Great Britain and Ireland at their January meeting, elected the following distinguished vice-presidents of the Union:—The Rt. Hon. the Earl of Onslow, G.C.M.G.; the Rt. Hon. Earl Roberts, K.P., G.C.B., the Rt. Hon. the Earl of Lonsdale, the Rt. Hon. the Earl of Plymouth, Lord Hugh Cecil, Sir Hickman Bacon, Bart., J.P., D.L.; Sir Lindsay Wood, Bart., J.P., D.L.; the Rt. Hon. Sir J. H. A. Macdonald, K.C.B.; Sir Hugh Bell, Bart., J.P.; Sir David Salomons, Bart., J.P., D.L.; Sir A. Acland Hood, Bart., M.P.; Sir W. G. D. Goff, Bart.; Col. Bowles, J.P.

At the same meeting the Earl of Mexborugh, W. Birtwistle, J.P., and 20 other automobilists were elected to life-membership, and a further addition of 200 ordinary members, since the last meeting, was reported. The growth of the Union has been very rapid, and it now numbers considerably over 10,000 members.

The Directors of the Gaulois Tyres, Limited, have made a contribution of 25 guineas to the Legal and Legislative Defence Fund of the Motor Union. The thanks of the Union have been conveyed to this well-known Company for their generous support. Altogether the sum of £1,250 has now been contributed to this important Fund.

Motor Union First Provincial Meeting of 1906.

IT is proposed that the first provincial meeting of the Union this year shall be held at Birmingham. The date provisionally arranged is the 26th of May. The committee will meet at the Grand Hotel in the morning, and an interesting programme is under consideration for the afternoon. In the evening there will be a general reunion at the Grand Hotel, when the fifth Annual Dinner of the Midland Automobile Club, and the fourth Provincial Dinner of the Motor Union will be combined in one event. The Midland Auto mobile Club have all the arrangements in hand.

Motor Union "Season Tickets."

IN addition to the list of Provincial Exhibitions, published in a recent issue of THE AUTOMOTOR JOURNAL, to which free admission may be obtained on production of Motor Union tickets of membership, it was arranged for the same tickets to pass, without charge, into the Exhibition which is being held this week at Edinburgh, in the Waverley Market.

Motor Yacht Club.

FEBRUARY 27TH has been fixed for holding the Annual General Meeting.

Nottinghamshire A.C.

AS usual, the Annual Dinner of this Club, held at the Victoria Station Hotel, last week, was an unqualified success. Mr. Charles Hardy presided over a company of about 100 members and friends.

Mr. H. Belcher, in proposing the toast of "The Parent Club, Motor Union, and Automobilism," referred to the successful establishment in London of the motor omnibus, and pointed the moral by suggesting that the Corporation of Nottingham might pause in their proposition to lay down tramways for Sneinton. He believed they intended to spend something between £100,000 and £120,000 in putting down the system, and in street improvements to make room for the trams. Yet, if it were not for the prejudice against motors generally, they could provide a motor 'bus service through Sneinton, which would not in any way interfere with property, which would turn any corners there were to be negotiated, and which would not require the widening of any streets, for about £12,000. For that sum they could put down 15 motor 'buses, which would give a very good service, and save the town the enormous outlay that was contemplated. He thought the Notts Club might well take the matter up with the Corporation.

Mr. Rees Jeffreys, in responding on behalf of the Motor Union, naturally touched upon the Election question, and said it had done a great deal to educate not only the Legislature, but the electorate in the utility of the motor car, and it was safe to say that the new House of Commons would be far more sympathetic towards the industry than the past had been, while it had been fortunate that so many of the voters had been taken to and from the polling booths in cars, enabling them for the first time to realise the wonderful control that the drivers exercised over them. Whether the country

The Automobile Association's First Annual Dinner at the Trocadero Restaurant on Thursday, January 25th. Chairman, Col. W. J. Bosworth.

adopted Protection or stuck to Free Trade, it certainly would have to have, in a commercial country, an efficient and cheap system of land transport, and that could only be secured by making full and unfettered use of the motor vehicle; and it was their duty, both as clubs and central organisations, to advance the benefits of the motor as much as possible.

Amongst the other speakers were:—Messrs. A. Barlow, Claude Johnson, E. M. C. Instone, Clay, Charles Hardy (the president), and Booth Granger (the hon. secretary).

An excellent musical programme gave little chance for conversation between the speeches.

Yorkshire A.C.

At the annual general meeting on January 26th, held at the Leeds Great Northern Hotel, Earl Fitzwilliam was elected president, and the following members were elected as vice-presidents and to the committee for the ensuing year:—

Vice-Presidents.—A. W. M. Bosville (Bridlington), B. Bagshaw (Leeds), C. B. Crawshaw (Dewsbury), W. Penrose-Green (Leeds), H. R. Kirk (Leeds).

Committee.—E. Watson (Leeds), A. Towler (Ilkley), P. A. Stanier (Leeds), A. W. Dougill (Leeds), E. Faiers (Bradford), H. A. Jones (Bradford), R. Winn (Leeds), E. H. Hepper (Leeds), Dr. Rumboll (Leeds), A. Exley (Leeds), A. W. Roslington (Leeds), A. J. Hare (Roundhay).

Hon. Secretary.—C. P. Wilson (Leeds).

Hon. Treasurer.—L. Hey (Leeds).

Hon. Solicitor.—Alf. Masser (Leeds).

CORRESPONDENCE.

SCHOOLS FOR MOTOR MEN.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—The increasing number of motor schools, the advertisements of which are a constant feature of several daily newspapers, has led to some enquiry into the *bona fides* of these establishments, and it is not surprising to find from evidence brought forward by "pupils" who paid their fees, and received practically no useful information in return, that some of the "schools" are worthless from the point of view of the student.

We were particularly interested in some remarks made by Mr. Cecil Edge in the *Daily News* a short time ago, as to the time needed to obtain a thorough knowledge of motor car construction, Mr. Edge contending that it is only by actual experience in driving and in dealing with breakdowns as they occur, that the average chauffeur can gain the kind of experience he really needs. Mr. S. F. Edge in the same issue of the same paper, also put great stress upon the necessity of a perfect mechanical training, and intimated that he was prepared to supply competent motor mechanics from the home of the celebrated Napier.

Everyone will admit that such training, whether achieved in big works such as the Napier, or upon the road in actual driving experience, is far more valuable than any amount of training acquired at a motor school, and from a purely mechanical standpoint this is quite correct.

But there is another aspect of this question which seems to have escaped notice. Is it not a fact that the great majority of car mishaps result from tyre punctures, bursts, or other tyre defects? Although admittedly vastly improved during the last few years, we think it is indisputable that the tyres are still the weakest feature in motor car construction at the present day, absorbing quite 75 per cent. of the total cost of car upkeep. This being so, is it not essential that every chauffeur should have as good a tuition in tyre fitting and repairing as in the purely mechanical side of the motor car, more especially so when it is borne in mind that the result of that tuition should be a greatly diminished cost of tyre upkeep?

Engine construction has attained such a high level of efficiency that engine breakdowns are now never very serious. On the other hand, tyres are always prone to puncture, and subject to other troubles. They need periodical attention, no matter how good they may be, and a chauffeur or motor mechanic who has availed himself of our free school of tyre repairing by vulcanization, can apply the proper remedies at the right time, and greatly prolong the life of the tyres in use.

A fully competent chauffeur or mechanic should be able to repair tyres in the garage or upon the road as the circumstances demand, and in order to make every such chauffeur fully competent to do this, we opened, some time ago, a free school of instruction in tyre repairing, at 39, Great Eastern Street, and, as a result, we have been able to recommend chauffeurs and mechanics for positions which they could not have applied for otherwise.

It seems to us, therefore, that the education of the chauffeur or motor mechanic is not complete unless he can execute emergency tyre repairs, and if he cannot do these, it is obviously his own fault, for our free demonstrating school is open to anyone at any time who cares to avail himself of its great advantages.

Yours faithfully,
HARVEY FROST AND CO., LIMITED,
H. Harvey Frost, Managing Director.

January 23rd.

INACCURATE DESCRIPTIONS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—We notice, in a description of the Lacoste magneto that appeared in a contemporary of yours, that the high-tension distributor of this machine is described as a jump-spark type, and we should be glad, therefore, if you would kindly publish this letter, so as to remedy any misconception that may have arisen over this point.

The high-tension current, in the Lacoste magneto, is distributed through "rub contact" by means of a small steel arm, fixed to the half-time shaft of magneto, carrying at its extreme end a small nickel knob which rubs on to raised nickel studs set at certain intervals in a solid block of vulcanite, this vulcanite being enclosed in an aluminium casing.

The steel blade is so set that the knob it carries touches the raised nickel studs with very little pressure, and when revolving between the nickel studs, does not touch the insulating material at all, this being to prevent any deposit of metal particles on the insulation, which might short one stud to another.

What we think probably misled the writer of the article in question, is the fact that, if the magneto has run for a very long time without attention, and the distributor blade having become fatigued, or the knob on its extremity worn, so that the latter does not make actual contact with the studs, this would in no way prevent the efficient working of the magneto, as the high-tension current would then be transmitted by jump-spark, though across a very small gap indeed, as immediately the knob ceased to rub the nickel studs, there would be no more friction, and the gap would not be widened.

We know by experience that this gap only affects the magneto in that it makes starting slightly more difficult. To overcome this only takes a few seconds for either replacing the blade or bending out the existing one.

Faithfully yours,
J. LACOSTE AND CO.,
Jan. 29th. R. A. Cheswright.

THE FLYING PROBLEM.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Replying to the letter of Mr. A. V. Roe, although I should have liked to comply with his request for an illustration, in view of the fact that the principle of my machine is an entirely new one, I can hardly disclose the idea before it is protected not only in Great Britain but abroad. Mr. Roe overlooks in taking up the brief for the aeroplane the great primary and initial difficulty with all aeroplanes, viz., starting from the ground. There is also a much less difficulty, but one that must be considered nevertheless, viz., the alighting on return to earth without undue velocity. This will necessarily arise, although we do not hear much of this difficulty from the Wright Brothers or the other experimenters. A bird always turns its spread tail downwards just before alighting, to arrest its motion. Something similar to this action is necessary. A small double aeroplane that I released from a kite on Wimbledon Common in 1894, although very lightly constructed of bamboo and paper, came down with such velocity, although travelling in a line not more than 10 or 12 degrees from the horizontal when it reached the earth, that the bamboo frame was smashed.

What is required is an apparatus that will lift vertically or nearly so for a certain distance, before bringing the equivalent of the aeroplane into action. Then the two should operate together, the former controlling and guiding the erratic tendencies of the latter.

An aeroplane will only be usable, whatever the success and skill eventually attained with it, in a treeless and houseless country. The sand dune, in fact, is the best ground for the use of the aeroplane, and sand dunes are not everywhere obtainable. The simple aeroplane, it is obvious, could not be used in, or in the neighbourhood of, a city for instance, and its use will be very limited if it is usable only on land bare of every obstruction, such as trees or houses. The insurance premium on the lives of passengers of an aeroplane proposed to be operated in the neighbourhood of trees would, I believe, be prohibitive.

My principle is one that admits of complete control and dirigibility of the whole machine. Even in the small model this was sufficiently proved to my satisfaction, as I could set it to travel at almost any angle with the wind, and I am confident that on this principle the controllable, useful and commercial machine will come when it comes. I believe that even the eagle has some little difficulty in rising from level ground. I do not know whether the albatross has a like difficulty, but I should imagine it would have. An albatross might find a little difficulty in getting out of St. Paul's Churchyard, for instance. A commercial aerial machine must carry passengers with the same degree of safety as the train and the motor car.

Yours faithfully,
Jan. 29th. J. D. ROOTS.

WEIGHT OF MOTOR CAR BODIES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I notice in your last issue some particulars of the regulations which will be made in connection with the Circuit Européen. If it is not too late, I should like to protest against the unreasonable weight which is going to be fixed as a minimum for the carriage body work. It seems to me that in a costly trial of this description every effort should be made to embody in the rules regulations which will be practicable, and which will give information and guidance to the constructor of motor vehicles as well as to the general public.

I take it that most of the competitors will be representatives of motor car builders, and those who enter, and go through the trial successfully, will necessarily expend a very considerable amount of time and money. Under the circumstances, I think that as the weight of carriage bodies to-day is a matter demanding very careful consideration, it will be an excellent opportunity—as the course is a long one—of obtaining data as to the behaviour of the carriage work quite as much as the mechanism forming the chassis. I consider that a limousine body to carry five people in the back, with the parts specified in the draft rules, should not weigh more than 6½ cwts. at the outside, whereas a minimum of 8·84 cwts. has been apparently decided upon. Now that the public demand is in the direction of much longer wheel bases, and more luxurious body work, tyre troubles are becoming a serious question. Under the circumstances, it would surely be a step in the right direction if our carriage builders took advantage of this trial to see what could be done in the way of building a strong, serviceable, and yet light carriage body. I personally believe that there is a very great deal yet to learn in this connection, and should like to see the rules framed so that a maximum instead of a minimum weight of carriage body were fixed, considerably lower than the figures already specified, and a thorough examination made into the condition of the body both before and after the trial.

Some little time ago I saw a paragraph in one of the papers that the firm of Michelin and Company were proposing to offer a prize for a competition in motor carriage bodies, owing to the fact that they were becoming so heavy that the tyres were suffering in consequence. I have personally seen examples of what I consider unnecessarily heavy carriage work from some of our leading coachbuilders, and I think that we should take advantage, if possible, of this opportunity in settling a reasonable maximum for the weight of various standard bodies.

My firm are entering for this competition, and as we shall build our own carriage bodies we should like to obtain from the trial all the data possible relating to the dimensions, shape and weights of the body work, as well as the rest of the car. The majority of the measurements specified seem fairly satisfactory, with the exception of the height of the roof from the frame. I think this dimension should not exceed 5 ft., whereas 5 ft. 3 in. is specified. Some latitude should be allowed in the direction of measurements as well as in the weight of the carriage work, so as to obtain each maker's idea as to what he considers the best.

The question as to how the marks should be awarded could be arranged without any difficulty, as, if a competitor runs with a very light body, which during the trial shows signs of weakness, marks could be deducted, which would put him quite on a level with the competitor who had embodied substantial carriage work in his car.

As I consider that this contest is likely to be a very important one, I should like to hear what your readers have to say on this point, and, thanking you in anticipation for inserting this letter,

I remain,
Yours faithfully,
THE AUSTIN MOTOR COMPANY, LIMITED.
Jan. 30th. H. Austin, Governing Director.

FOUR CYLINDERS AND SIX CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—My challenge to test the comparative merits of 6-cylinder and 4-cylinder motor cars has elicited two possible acceptances, from Mr. Claude Johnson and Mr. S. F. Edge, respectively. The former does not think that a speed contest would settle the matter. For my part I am quite willing to take into account, not merely speed over the whole course, but also hill-climbing powers, speed on the level without changing gear ratio, petrol consumption, smoothness of running, &c.

Mr. Claude Johnson's suggestion that "the jury should consist of three ladies and three gentlemen who have been in the habit of driving in carriages drawn by horses, and who are not wedded to any particular form of motor traction," is, in my opinion, undoubtedly the weakest possible. On the other hand, I am prepared to accept the verdict of experts, and people who have had practical experience of motors generally, rather than that of persons who know nothing, or next to nothing, about them. One might as well ask naval officers to adjudicate on technical matters connected with cavalry.

I am very pleased to note that my friend, Mr. S. F. Edge, is ready to have a friendly match with me. I am also prepared to go to the Continent and have the match there, but not with a racing car. I consider that the match should be with *bona fide* touring cars, as sold to the public. I know this will open up a fresh discussion as to what is a touring car and what is a racing car. I think this has been solved by the Automobile Club of France, who recently, I understand, decided that cars with greater engine capacity than four cylinders of 130 mm. bore could not take part in the "Circuit Européen."

According to Mr. Edge's reply to my letter, I am under the very strong impression that the 6-cylinder car which he proposes to match against my 4-cylinder car, is undoubtedly a racing car.

As regards the test for silence, this is a very difficult one to carry out, whilst wear and tear of machinery may be left out, for I do not think for one moment that any car that would take part in such a test would be so badly constructed as to show any wear and tear of machinery. As to the wear and tear of tyres, a great deal depends upon the way the car is driven, and the type of clutch. Petrol consumption would be most interesting, also hill climbing and speed on the level with same gear ratios. As regards the slow running on top speed, and running say 500 miles without changing speed, I do not attach much importance to them, as I consider that in order to obtain the maximum horse-power at the road-wheels under all conditions, it is essential to have gears with suitable ratios.

I am not in any way prejudiced, and am quite prepared to advocate 6-cylinder cars in place of four, if cars of that type demonstrate to me their all-round superiority to cars of similar horse-power with four cylinders.

I am, Sir, Yours faithfully,
January 25th, 1906. H. H. P. DEASY.

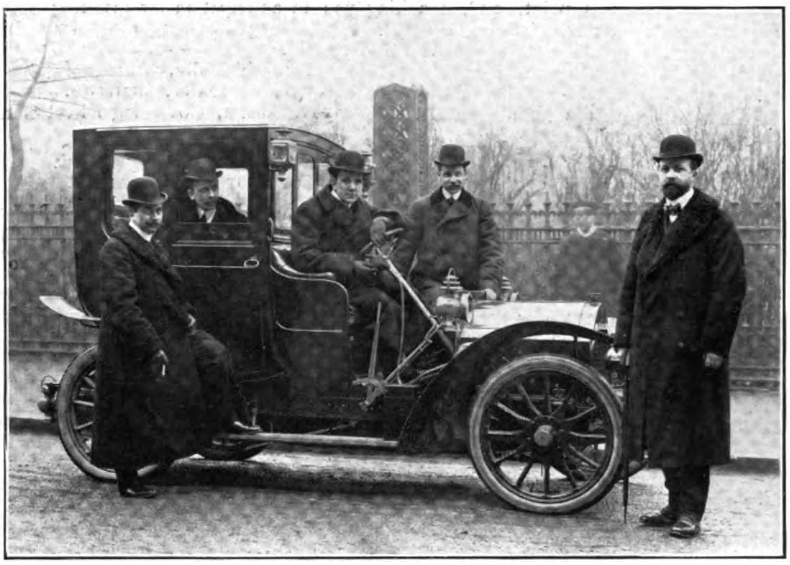
Free Inspection of Argyll Cars.

WITH reference to the form for their periodical report which Argylls, London, Limited, have prepared, and to which we referred last week, we learn that this has been copyrighted at Stationers' Hall.

Newcastle-on-Tyne Exhibition.

THE first list of exhibitors at this Show, which will be held February 9th to 17th, in the New Exhibition Hall, St. Mary's Place, includes most of the leading British cars and many of the best-known foreign makes, in addition to one or two motor boats. The Exhibition is under the patronage of the Right Hon. the Earl of Scarborough, Lord Armstrong, Lord Berwick, and many other distinguished personages. Five per cent. of the gate receipts will be given to local charities. Success should be assured for exhibitors, as every motor and allied trader will receive an invitation and free ticket. In addition ten thousand special complimentary invitation tickets will be sent to magistrates, solicitors, doctors, &c., that is, all likely buyers of a motor car in the north-eastern district will receive a free ticket. Also any member of the Motor Union will be admitted free to the Show on production of his membership card. The band of H.M. 1st Life Guards has been specially engaged.



An interesting group of motorists photographed by us one day last week near Regent's Park. Mr. Charles Jarrott at the wheel, and Mr. W. M. Letts, standing on the left, are readily recognised. The other automobilists in the picture are Baron de Turckheim, M. Turcat, and M. Mery, who are so well known in connection with the celebrated De Dietrich Cars.

An Amazing Piece of Law.

SIR RALPH LITTLER, K.C., Chairman of the Middlesex Sessions, on Saturday last laid down the rule (it is thus described by the daily papers, but we should prefer to say, "uttered the astonishing opinion") that "the motor car on the highway occupies the same relation to slower vehicles that a steamship does to sailing vessels at sea." "A motor car," he said, "must give way to slower vehicles." We should very much like to know where Sir Ralph Littler obtains justification for his pronouncement. There is nothing of the sort in the Highways Act, nor in any of the Acts which have regulated road traffic since. The steam vessel at sea gives way to the sailing vessel—and it is, we believe, an ordinance of maritime law that it should do so—because the sailing vessel has to tack, and if she were interrupted in changing from one "leg" to the other when, as sailors say, she is "in stays," the consequences might be disastrous. But there is nothing of the kind with the slower traffic on the road, whether horse drawn or otherwise. The pronouncement, in fact, is sheer nonsense, and Sir Ralph Littler had no more justification in making it than if he had announced his profound conviction from the Bench that the motor car has no right on public highways at all.

Cowled Chauffeurs.

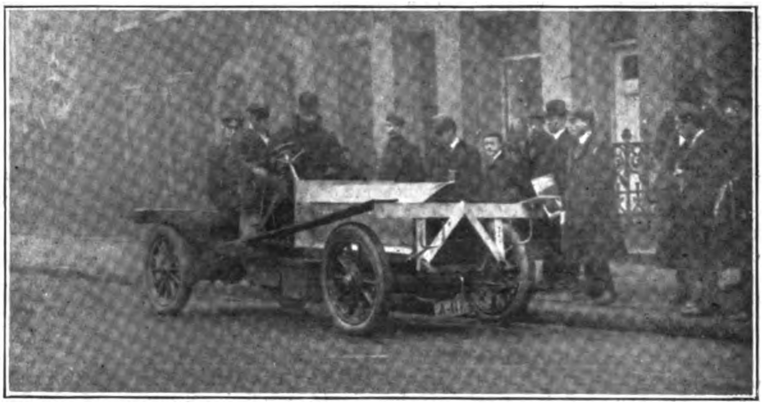
JUST as in the Middle Ages the church accommodated itself (with difficulty) to the theory that the earth goes round the sun instead of the sun round the earth, so it is now beginning gradually to recognise and appreciate the automobile, and the monks of the famous hospice on the Great St. Bernard who have been so long and justly famous for their exploits in saving snow-drifted travellers and tourists, are about to adopt the *rôle* of chauffeurs. We referred some time ago to the arrangements being made for transporting supplies from Valais to the great monastery. There has been some difficulty in obtaining permission, but that has now been got over and cars specially constructed to surmount the steep gradients encountered on the road, are being built and are to be driven by the monks, who will preserve their medieval cowls on the modern motor vehicles which they drive.

An Attractive Load for the Motor 'Bus.

THE motor 'bus is a general favourite with Londoners just at present, but to Miss Kate Cutler, of the Gaiety Theatre, must be accorded the palm of smartness for recognising its adaptability and the advantages of its roominess for carrying out the quick change of costume between one theatre and another which artistes who have had to appear on different stages in different characters on the same evening have hitherto usually carried out in the private brougham or the homely growler. Incidentally, too, no doubt the passage through the streets of a motor 'bus be-curtained and arranged (also placarded) as an actress's dressing-room could not fail to impress the popular imagination in the enterprising and charming actress's favour. One of the "Vanguard" 'buses which had previously been plying between St. John's Wood and Victoria, was accordingly transmogrified in the manner described, and one evening last week it awaited Miss Cutler at the Gaiety Theatre, conveyed her at 9.30 thence to the Palace Theatre, where she took her part in "Hero and Heroine," dressing for the part in the 'bus on the way, and afterwards returned to the Gaiety, where at 10.35 she was enjoying an impromptu meal on the stage at the "Crimson Butterfly" Restaurant.

The Institute of British Carriage Manufacturers.

MR. ARTHUR F. MULLINER has been elected President of the Institute of British Carriage Manufacturers.



Baron Turckheim, of the De Dietrich Company, together with M. Turcat and M. Mery of the same firm, have been paying a visit of inspection to England, and have been having a good look round several of the leading factories, *en passant*. Amongst these was the Napier works, where the visitors were particularly interested. In addition, Baron Turckheim availed himself of the opportunity of having a run with Mr. Cecil Edge on a 6-cylinder Napier. The snap which we are able to reproduce above, is a record of this interesting little episode. That the ride was an unexpected one, may be gathered from the temporary mudguards and their methods of fixing, which were adopted for the occasion.

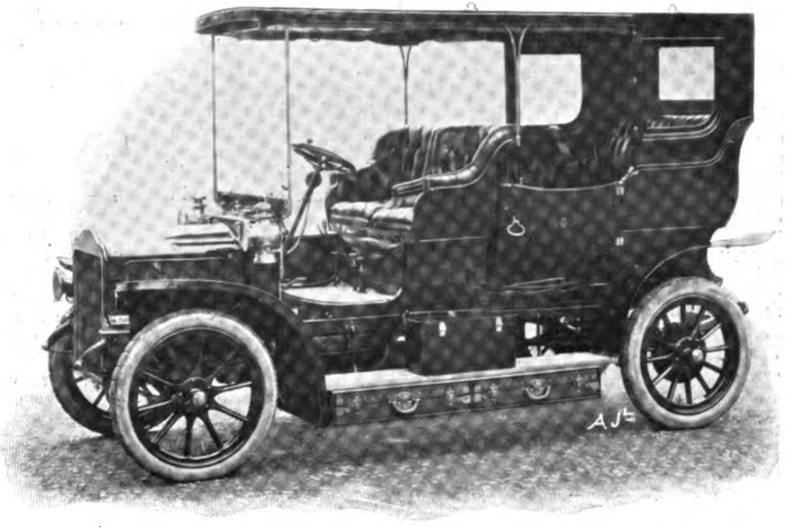
COMMERCIAL POINTS.

Motors for Ambulance Work.

FOR some time past the Council of the St. Andrew's Ambulance Association in Glasgow have had under consideration the question of pressing the petrol motor into their service. The question, naturally, demanded careful and critical examination, as the first essential for an ambulance vehicle is that it shall not be easily liable to breakdown or other derangements. After weighing up the pros and cons, and examining the designs and mechanical details of a number of leading makes, we learn that the council have placed an order with the Argyll Company for a 16–20-h.p. chassis with specially-designed body. In the internal arrangements of the vehicle a number of modifications will be introduced to suit the special work, largely on the initiative of Mr. A. T. Reid, of Hyde Park, and Colonel H. J. Barnes, R.A.M.C., secretary of the Association.

THE 6-cylinder Napier car, driven by Mr. Clifford Earp, which has made such splendid running at the Florida meeting, was, we learn, fitted with "Castle" accumulator and "Castle" distributor coil, both being standard models.

WE learn that H.M. The King's latest car has been fitted with the new pattern Continental tyres of a specially large size of the non-skid pattern. The car, which is fitted with a powerful engine, has a heavy covered-in carriage body, and consequently a great strain is thrown upon the tyres, and in view of the fact that a carriage for the use of the King must necessarily be as free as far as possible from tyre troubles, the selection of the Continental tyre is a compliment to the manufacturers, worthy of notice.



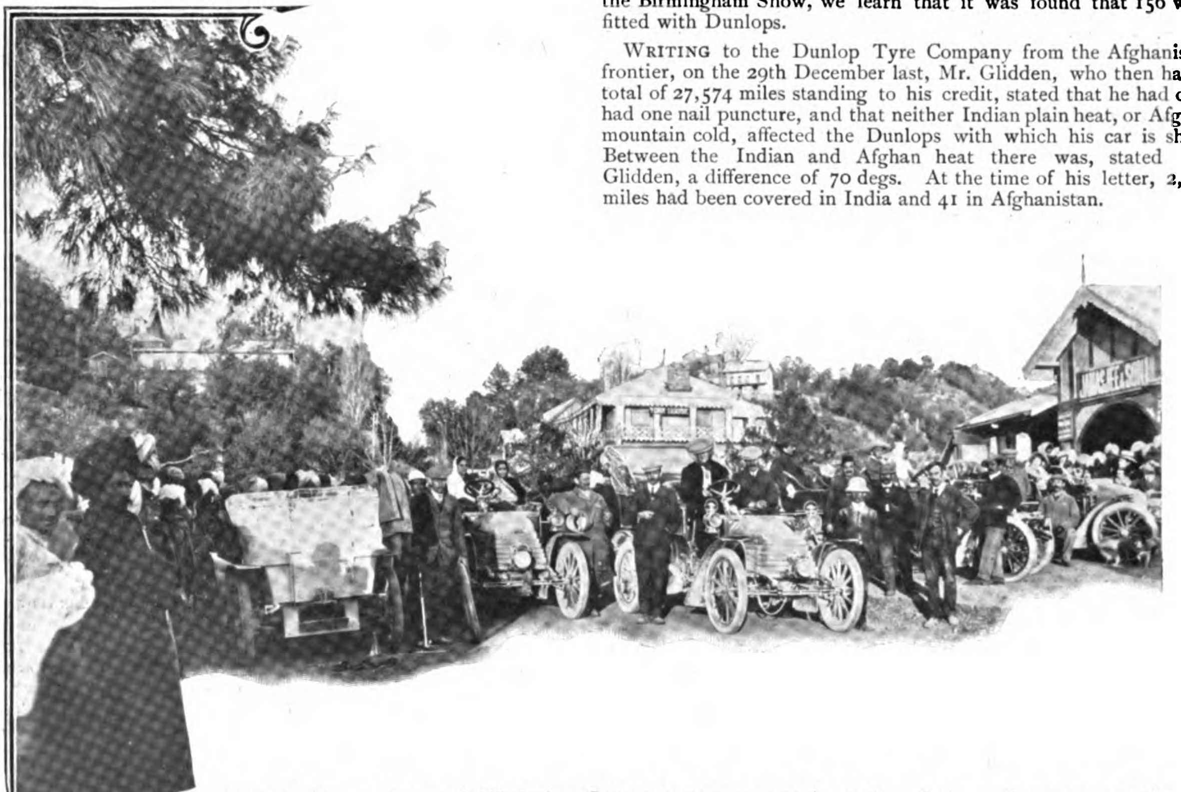
A BEAUTIFUL STEAM CAR.—One of the most recently produced White Steam Cars, which has just been completed to the order of the Duchess of Manchester.

SIRDAR tyres are being fitted to the new State carriages of Their Majesties the King and Queen of Norway.

MR. J. W. ADAMS, Messrs. Humber's sales manager, is leaving on an extended tour round the world, calling upon many of the numerous foreign agents of Humber's who have not previously been visited by a representative of the firm.

As the result of a count of motor tyres fitted to cars exhibited at the Birmingham Show, we learn that it was found that 156 were fitted with Dunlops.

WRITING to the Dunlop Tyre Company from the Afghanistan frontier, on the 29th December last, Mr. Glidden, who then had a total of 27,574 miles standing to his credit, stated that he had only had one nail puncture, and that neither Indian plain heat, or Afghan mountain cold, affected the Dunlops with which his car is shod. Between the Indian and Afghan heat there was, stated Mr. Glidden, a difference of 70 degs. At the time of his letter, 2,433 miles had been covered in India and 41 in Afghanistan.



Very large numbers of Wolseley Cars are now in use in India, their performances in the Delhi-Bombay, Bengal, and other trials having brought them into great prominence. In nearly all combined excursions of motorists in India, one or more of this type of car are included, and our picture shows an excursion which was made to Muree, a Punjaub Hill Station, situated 7,500 feet above the sea level. **The party was organised by Mr. Lalakka, of Bombay, and included:—Mrs. Mansfield (wife of General Mansfield), Major Warren, Captains Shuttlebrook, Fitzgerald, and Williams, Lieut. Wood, Mr. Dhonjibhoy, C.I.E., Mr. and Mrs. N. J. Jamasjee, Dr. and Mrs. Setna, Mr. and Mrs. Boga.**

Arrol-Johnston Extensions.

MUCH additional machinery of the most approved description having been recently laid down at the works of the New Arrol-Johnston Car Company, Limited, Paisley, Scotland, has enabled this progressive firm to greatly increase their facilities for the output of their popular cars and commercial vehicles. In connection with the Company's extensions, a large building belonging to the firm, hitherto unoccupied, is being fitted up as a running and repair department, so as to relieve somewhat the pressure on the main premises.

THE Scottish Motor Engineering Co., Ltd., of Granton Harbour, Edinburgh, have been appointed official repairers to the Automobile Club for the district. The Company inform us they have fitted up special repair shops to meet the requirements of owners of every type of car, and keep a special staff of men on the premises for this purpose.

Turin Motor Exhibition.

AMONGST the British firms whose cars will be represented at this important Show, opening on Feb. 3rd, will be Argyll Motors, Ltd., who will stage two of their most popular types of cars. One of these is a 10–12-h.p. 2-cylinder side-entrance car, and the other a 16-20-h.p. 4-cylinder. These cars will be shown in the stand of the Société Anonima Garage Croizat, the Argyll Co.'s agents in Turin. We are informed that "Argyll" cars are selling readily in Italy, there being now a large and increasing number in use in the country, and more particularly in the North.

LEGAL INTELLIGENCE.

"Motor Schools"—More Alleged Frauds.

RISKI MEDAWAR, 22, a Turkish subject, described as a motor car dealer, and John Raymond Kerr, 21, of Warwick Gardens, West Kensington, two well-dressed men, were on January 26th, at Westminster Police Court, charged on warrants with conspiring to obtain sums of 4 guineas and other sums by false pretences and fraud. It is alleged that they obtained money from a number of young men who were induced by advertisements and circulars to apply for motor car instruction at 47, Victoria Street, and Cartaret Street, Westminster.

Evidence of prisoners' arrest was given by Detective Cock, who said that many young men had lodged complaints of having been defrauded. Medawar remarked, "They will have to prove that it is a fraud." Kerr said nothing. Prisoners were remanded in custody.

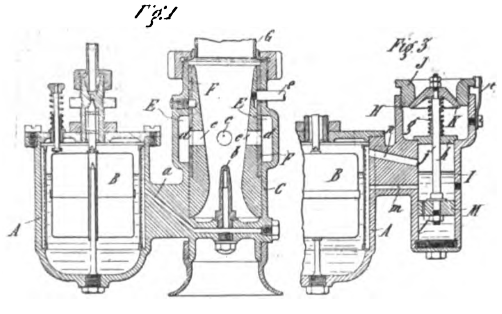
* * * *

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

20003. 3rd October, 1905. Improvements in Air Carburetting Apparatus for Internal Combustion Motors. Georges Richard, 108, Rue St. Maur, Paris. Date under International Convention 10th October, 1904. The feature of this invention is that the stem of the valve which allows the passage of supplemental air, carries a piston which acts as a controlling brake in being displaced in a liquid which passes from the one side to the other of this piston through an orifice of small section formed through the piston, thus constituting a dash-pot device. There are four figures. Fig. 1 is a vertical section. Fig. 3 is a part vertical section. The reservoir, A, with constant level has a float, B, the coned stem of which acts as a valve for the admission of the liquid supplied. The channel, *a*, communicates with the nozzle, *b*, situated at the centre of the chamber, C, through openings of which the external air enters. There is thus formed at the height of the nozzle a gaseous mixture to which is added the air admitted through the openings, *c*, to an annular channel, E. A cylindrical slide, F, having holes, *d*, of the same section as the openings, *c*, enables the openings, *c*, to be more or less closed or opened by turning the slide by the rod, *e*. The tube, G, conducts the gaseous mixture to the motor. The annular channel, E, for the admission of the supplemental air communicates through a passage with a vessel composed of an upper larger part, H, and another cylindrical part, I. The part, H, has screwed into it the seat, J, of the valve, K, for the admission of the supplemental air. On the underside of this valve is a spring, *g*, which tends to raise the valve against its seat. This spring bears, on the other hand, upon the cap, *h*, which separates the part, H, from the cylinder, I. By screwing the seat, J, more or less into the part, H, the tension of the spring which acts under the valve is regulated, the seat, J, being secured in the position imparted to it by means of a spring-catch, *i*, which engages in notches formed in the periphery of the seat, J. The stem, *j*, of the valve, K, passes loosely through the cap, *h*, into the interior of the cylinder, I, where it carries a piston, M, having a small passage, *l*. Two channels connect the vessel, A, with the cylinder, I; the one, *m*, is situated below the level of the liquid in the vessel, A; the other channel, *n*, connects the space above the liquid, so that there exists an equilibrium of pressure in A and in I. The suction-action of the motor acts through G *c* E. The spaces above the liquid in A and I are necessarily open to the suction, as if they were closed vapour pressure might accumulate, preventing the liquid in A from being maintained at the proper level. The liquid in the dash pot being the same as that fed into the apparatus, it will always be renewed, so that it is not subject to thickening after a time.—January 10th, 1906.

Fig. 1



1035. 19th January, 1905. Improvements in Carburettors for Oil Engines. Hedley S. Moorwood, Glenwood, Dore, Sheffield, and James F. Bennett, Gordon Cross House, Dronfield, Sheffield. The main object of this invention is the construction of a simple apparatus for producing a combustible mixture of air and hydrocarbon oil of high-flash point. Apparently, therefore, the title should have been "Improvements in Vaporisers for Oil Engines." There are seven figures. Fig. 1 is a vertical section. A is the vaporising chamber, having around it a jacket, B, through which the exhaust from the engine is passed. C is a passage extending across the interior of the chamber, A, through which the exhaust gases are also passed. This passage is enlarged at the centre into the form of a hollow ball. The exhaust gases are led in at the opening, D, and leave at E. At the bottom of the vaporising chamber is an air inlet passage, F, contracted at the top into a cylindrical opening within which is held a disc sprayer of somewhat less diameter, so that air on entering rushes through the narrow annular space left between them. The sprayer is formed of a disc at the top of a fixed stem, G, and a loose disc, H, resting above. The stem, G, has a central oil supply passage bored through it, and a stem projecting downwards from the upper disc fits loosely within the upper part of this passage, whilst its lower end serves as a valve to close the oil supply unless the upper disc is raised. A fine film of oil is left between the two discs ready to be sprayed as soon as the suction of the engine takes place. The lifting of the sprayer opens the valve and acting as a pump draws up a further supply of oil. I is a stop to limit the lift of the disc, H. The stem is secured at the bottom to a boss, J, carried by radial arms from a ring, J¹. The oil passage in G opens at the bottom into a corresponding passage in the boss, J, to which oil is supplied through one of the radial arms. Paraffin is supplied through an inlet supply pipe, K, and petrol through a supply pipe, L. This allows of petrol being used when starting and paraffin when the apparatus has become fully heated. M is a screw stop valve by which the supply of oil can be cut off or controlled. When starting the engine provision is made for holding up the disc, H, at this time by placing around the stem, G, a tube, N, having two pins projecting upwards from it to come below the disc, H, and lift it when the tube itself is lifted. To lift the tube a lever, O, turning on a fulcrum at O¹ is used, the lever being normally held out of action by a spring, P. R is a throttle by which the outlet, S, can be partially or entirely closed. The stem is held up by the action of a spring, U. The spring bears downwards upon a disc, V, placed above the cover, T. The cover, T, disc, V, and throttle valve, R, are all slotted, so that when desired air may be admitted through them to the vaporising chamber.—January 10th, 1906.

PASSING EVENTS.

Cars of To-day, and How to Recognise Them.

Most people, whether deeply interested in the automobile movement or not, like to know the build of cars that pass them on the road or in the street. With a view to rendering recognition of the principal types of vehicle as easy as possible, we this week commence a series of specially-arranged illustrations, under the heading of "Cars of To-day, and How to Recognise Them," which will be found to give the salient and characteristic features of the leading types and builds of present-day automobiles—including not only pleasure vehicles, but also such familiar objects in our streets as town vehicles and motor 'buses. Each of the leading makes or types is dealt with separately, and an indication is given of the various sizes in which similar types are built. On the right-hand side of the title is a small illustration of the complete car, and on the left, the country in which it is manufactured is denoted. Underneath are larger illustrations showing the most noticeable features of the vehicles in question, with arrows directing attention to them, while a short description sums up these leading peculiarities. These pages of The Automotor Journal will therefore constitute a graphic guide to practically every type of car on the market, and anyone with the exercise of a very little observation will be able to identify the build of any car at a glance.

◆ ◆ ◆

From the Heart, and Not as a Crank.

Attempts to resuscitate the "Juggernaut" in February, even such a mild February as we have had up to the present, are not likely to be very successful. It is in the sweltering dog-days, when the dust lies thick upon our highroads, that the worshippers of that monstrosity are most likely to be successful in infusing some appearance of life and vitality into his deflated carcase. All the same, the Marquis of Queensberry has made a gallant attempt to set the Juggernaut on his legs again, and it was the Marquis of Queensberry, as most of our readers will recollect, who applied in the open Court to a Metropolitan Magistrate to know if he might shoot at motorists with a pistol. Lord Queensberry is accordingly hardly to be taken as a serious personage. No, we do not think the Juggernaut will ever become a terror again, and certainly the month of February is a very unsuitable time to attempt his resuscitation. Still, Lord Queensberry must be credited with doing his best. This is what he says in a letter to the *Daily News* and other lay papers, referring to the unfortunate accidents to two children, named Ellen Broad and Thomas Snapes, who were recently killed by motor cars, in which coroners' juries found that no blame attached to the motorist:—

> In a morning paper of to-day, anent the deaths of Ellen Broad and Thomas Snapes, I find it under the following heading: "Child Runs Into a Motor. . . ."
>
> While winter was on us, and the roads were bad, where was the gentle motorist? We looked and longed again for the pleasant dust, and sniffed the air vainly for the spicy breezes, and listened hopefully for the cheerful grunt. Alas! he was at Monte Carlo taking his well-earned rest, or perhaps strengthening his nerves for the coming fray on his yacht in the Mediterranean, varied by an occasional dash ashore to sharpen up the wits of the very young and very old Continentals, or perchance in some savage land, showing to the astounded heathens (save the word!) the latest game of "hog-amok."
>
> But now, thank goodness! winter is waning. Once more the roads are drying up. Spring is knocking at the door, and all is bright and joyous, and, to crown all, the jaded motorist is back with ruddy cheeks and iron nerves, and funny oaths from foreign parts.
>
> But there is one thing mars the joyful season, and that is those abominable British children who will play marbles like we all used to in the good old days, and will go to school by the roads, as we used to in the good old days, instead of by the only safe modern way, over hedges and ditches: in fact, any d—d old way except the right one, and who will insist, as this daily tells us, on running into poor innocent motors. . . . And so the motor season commences.
>
> Good-bye, little Nellie Broad. Good-bye, little Tommy Snapes. Sleep well, you have earned better than most of us, who are older than you, your rest. Some words of that beautiful hymn, "We are but little children weak," should be your epitaph, and as sure as the sun rises, some Member of the new Government, of which I am an ardent, though voteless, supporter, will be your remaining little brothers' and sisters' champion. It was impossible to hope much from the last, as a search of the police courts will easily explain.

And he adds as a postscript, "I speak from the heart and not as a crank."

◆ ◆ ◆

Good May Result.

We are not sorry that Lord Queensberry has been stimulated into his ill-advised utterances. Except on the rare occasions when the British public loses its head, there is nothing so calculated to injure a cause in its eyes as exaggeration and unfairness. A better feeling between motorists and non-motorists is generally gaining ground as the result of the operation of causes to which we recently drew attention. One of the things most certain to prevent a recrudescence of prejudice is to find prejudice carried to burlesque extreme, particularly at a time of year when even the most prejudiced are not very angry with the motor car. Lord Queensberry, therefore, must be looked upon as having done a service to the industry rather than an injury to it. May all its enemies be as ill-advised, as unfair, and as immoderate in their language as his lordship! It is all we ask for. In fact, an effect of the kind has already been produced by Lord Queensberry's hysterics, as the *Daily News*, a day or so subsequently to the appearance of his letter, made the following very trenchant observation:—

> If he (Lord Queensberry) had taken a microscope and carefully searched the remote corners of the same newspapers that sported the lurid headline above, he would have found (in some of them) another paragraph about a child that was playing in the streets at Southwark, and was killed by a horse-drawn vehicle, but it didn't have any headline.

◆ ◆ ◆

The C.T.C. to Welcome Motorists.

The Cyclists' Touring Club has decided on what it terms "broadening the club's constitution." Hitherto, as everyone knows, it has been an organisation, and a very fine organisation, whose *raison d'etre* and sole occupation and business has been that of looking after and catering for the interests of the cycling tourist. It would not be exactly correct to say that its attitude to automobilism has ever been collectively hostile, but its friendship for the new locomotion, if it existed at all, has certainly up to the present been decidedly platonic in character. Not so very long ago, indeed, it was formally resolved not to admit motorists to the ranks of the club. Now, however, the club has decided on a course of action which is obviously intended to turn it into an institution designed to appeal to the touring automobilist as much as in the past it has appealed to the touring cyclist. The decision at which the Cyclists' Touring Club committee has arrived does not say this in so many words. It simply declares that steps are to be taken to "broaden the basis of the club so as to admit all tourists to membership." The expression "all tourists" does not of course specifically refer to automobilists, but pedestrian tourists are now few and far between—fewer and more far between than they used to be even when the Cyclists' Touring Club was at the zenith of its prosperity and membership. So we may be pretty sure that the Cyclists' Touring Club does not mean, by broadening its basis, merely to include pedestrians. It is automobile membership that it desires, and automobile membership that it evidently hopes to get.

◆ ◆ ◆

A Change of Attitude.

Automobilists generally will be satisfied to find that they will in future be able to reckon upon the co-operation, friendship, and support of so powerful a body, and one which possesses so admirable and far-reaching an organisation as the Cyclists' Touring Club. On certain points, the automobilists—or the bodies which represent their interests—have been in cordial co-operation with the Cyclists' Touring Club for a considerable length of time. We refer to such questions as the necessity of a universal law for the lighting of all vehicles after dark, the carrying of tail lights on all vehicles, and the important questions of highway administration, reform, and improvement, with which the Cyclists' Touring Club has cordially co-operated with the Roads Improvement Association, the A.C.G.B.I., and the Motor Union. From now on, however, we may reckon that we shall have the Cyclists' Touring Club's cordial co-operation and support on all subjects in which automobilists are interested.

◆ ◆ ◆

A Question of How Far.

How far the activity of the reformed Cyclists' Touring Club in supporting and assisting automobile interests is to be carried, is, of course, primarily a question for the Cyclists' Touring Club itself. One of the most useful directions, as far as its action in the past was concerned, has been to assist in the legal defence of cycling interests where they have been imperilled, doing, in fact, for the cyclist what the Motor Union in particular has made a speciality of doing for automobilists. We do not know whether the Cyclists' Touring Club now propose to act in the same capacity as legal advisers and assistants for prospective automobilist members. Considering the much smaller subscription required for membership to the Cyclists' Touring Club, and that the Motor Union has already established such an admirable record for the conduct and support of law cases in which automobilists have been concerned, it may possibly be as well if the principle of specialisation of function should still be retained, and that particular department still be left, in the future as in the past, to the Motor Union alone. This is, however, a matter on which we offer no opinion, and it is essentially one for mutual arrangement between the two bodies. Possibly, also, the matter of arranging tariffs with hotels—a movement of which the Cyclists' Touring Club was the pioneer organisation, and in which it performed, especially in its earlier days, such admirable service, may require reconsideration. The kind of tariff arrangements which are acceptable to the majority of touring cyclists, are not necessarily at all the same as those that suit the touring automobilist, and the general tariff established by the Automobile Club with hotel keepers who are placed on its lists, differs a good deal from the Cyclists' Touring Club tariff. Whether the Cyclists' Touring Club will adopt a modification of their tariff, or whether they could usefully arrange such matters in the interests of automobile members, is also one of the matters which must also be left for the future to decide.

A Testimonial to Importance.

In whatever way all these questions are ultimately decided, however, the recognition which the Cyclists' Touring Club is thus affording to automobilism by its proposal to identify itself with automobile interests cannot be regarded as anything but providing a very telling recognition of the immense growing importance of the automobile movement. It has been our pleasing duty to have to call attention, when summing up the events of last year, to the important evidence of the diminution of prejudice against the new locomotion which the history of last year provided. The new departure of the Cyclists' Touring Club is evidence of the further spread of the same spirit of tolerance. Some years ago cyclists were one of the classes of the community most bitterly opposed to automobilism. That the leading cyclist organisation should not only be willing but should practically be compelled to join forces with the motor car interest is in itself something of a phenomenon and the best possible evidence of the growth of a general friendlier feeling and a recognition of the growing importance and power of the automobile interest. Had the Cyclists' Touring Club taken this step earlier in the day, their action would have been even more keenly appreciated by the motoring community at large than it is now, for then there could have been no question as to the value of their co-operation. As it is, however, most of those to whom they now propose to appeal will feel that it is a case of "better late than never," but that it remains to be seen how far the Cyclists' Touring Club can establish itself as an automobile "power" in the land.

⊕ ⊕ ⊕ ⊕

Marked "Dead."

THE above title represents the present condition of the Bill for promoting the motor car road from Croydon to Patcham, near Brighton. As will be remembered, the preliminary examination before the Standing Orders Committee was adjourned for a week. When the subject came up again on Monday for further proceedings, the Parliamentary agents of the promoters announced that the said promoters did not intend to proceed with the Bill this session. We think the promoters have displayed distinct wisdom in coming to this decision, and we are thankful that what we have always regarded as a menace to the automobile movement is for the present, at any rate, defunct.

What is a Walking Pace for a Motor Car?

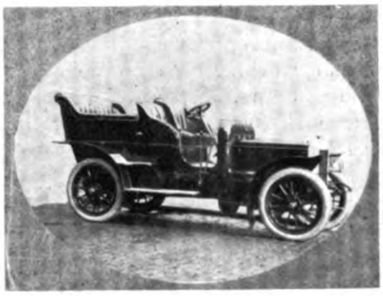
ACCORDING to the bye-laws of Northumberland, a vehicle proceeding at more than a walking pace must be furnished with two front lights after dark. A motorist was summoned for having only one of his front lights burning. Thereupon the solicitor pointed out that the bye-law was obviously framed with a view to horse-drawn traffic only, in which case the pace would, of course, be judged by whether the horse was walking or trotting. The solicitor asked the magistrates when they would consider a motor car going at a walking pace, and when it should be considered as going faster than a walking pace. The magistrates found the riddle too much for them, and dismissed the summons, suggesting at the same time to the County Council that the bye-law should be revised.

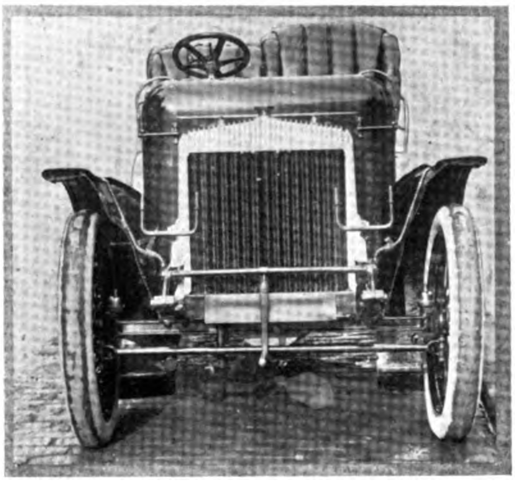
How to Recognise the Cars of To-day.

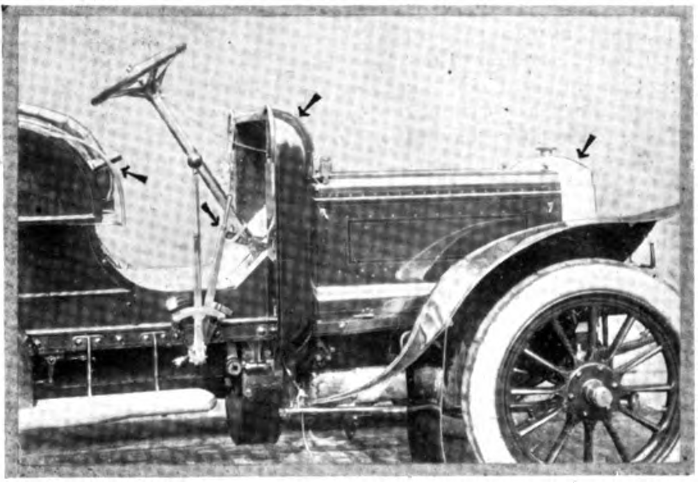
The Daimler

(BRITISH CARS)

28 H.P., 35 H.P., & 45 H.P.





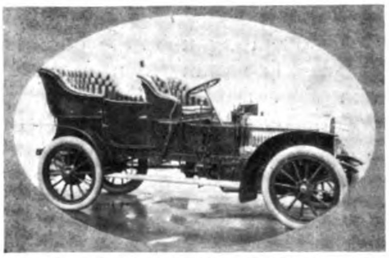


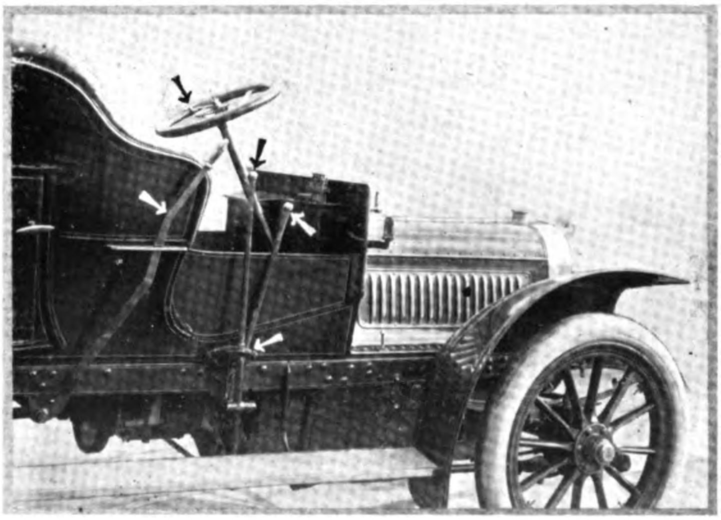
All Daimler Cars—built at Coventry—are chain driven and high-powered vehicles of large size. Their most noticeable features are the ALUMINIUM CASING ROUND THE RADIATOR, and the CURVED DASH—the latter is often copied, however, in other vehicles. Other characteristic details are the BRAKE LEVER (projecting from the side of the driver's seat), and the independent reversing lever. (See "AUTOMOTOR," Vol. X., Nov. 18th, 1904).

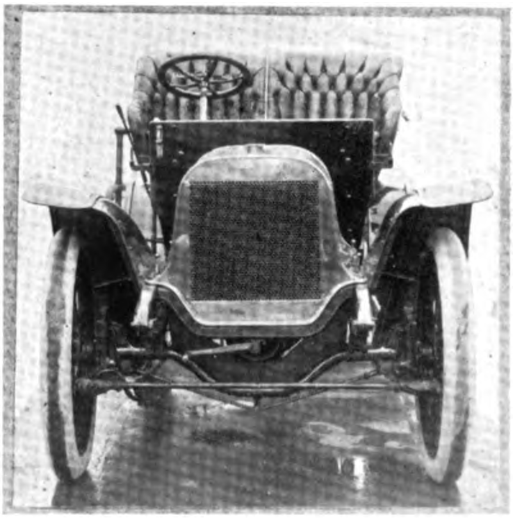
The Argyll

(BRITISH CARS)

10-12, 16-20, 20-24, & 24-30 H.P.







Argyll Cars—which are made in Scotland—are alike in their leading external characteristics, except that they vary considerably in size—and are of the "live" axle type. Peculiar to all are the RADIATOR, with its TUBES ARRANGED IN THE FORM OF A SQUARE, and the distinctive CURVATURE OF THE BONNET. The most noticeable details, however, are the CHANGE SPEED AND BRAKE LEVERS. (See "AUTOMOTOR," Vol. X., Oct. 14th to Nov. 4th, 1905).

THE 3-CYLINDER "NATIONAL" CAR.

SEVERAL important improvements have been made in the all British 3-cylinder car, which is built at Gainsborough by Messrs. Rose Bros., and for which Messrs. Lamb Bros. and Garnett are the sole agents, since it was last described in these columns,* and we are now able — with the assistance of photographs —to give some particulars concerning these new features. Being the only firm, so far as we are aware, to have restricted their attention hitherto to the production of a 3-cylinder type of vehicle having a vertical engine, the "National" car built by them is all the more interesting; it, in fact, stands to-day as one of the chief champions of the triple-cylinder principle—a principle which aims at inexpensive production combined with the advantages of multiple cylinder construction.

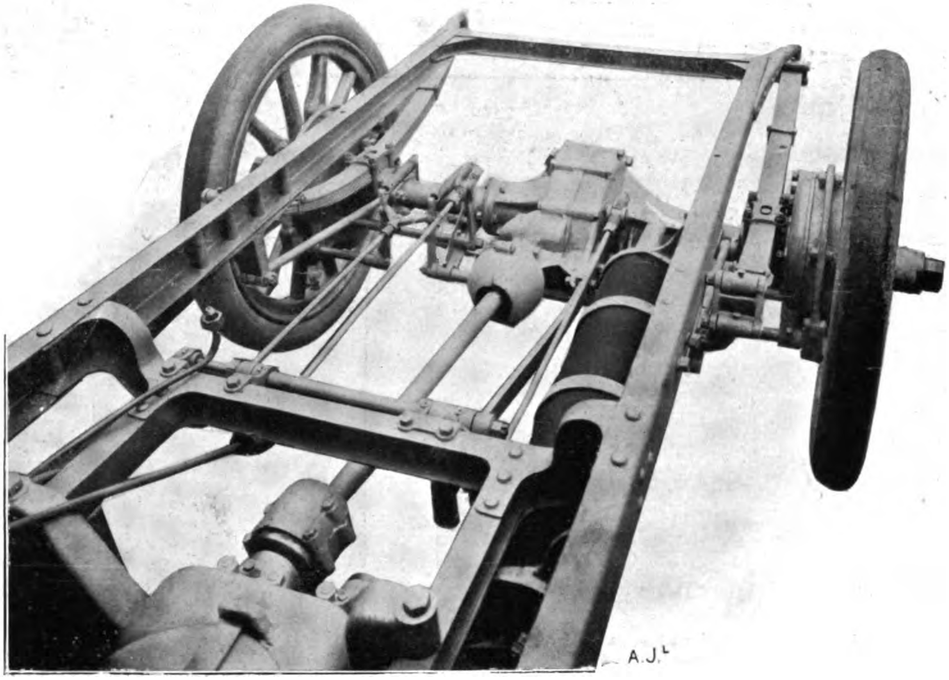


Fig. 1.—Rear portion of the 18-h.p. "National" Chassis, showing the arrangement of the hand and foot-brake mechanism on the "live" rear-axle.

One of the chief modifications has been the transference of the foot-operated brake from the transmission-gear direct to the hubs of the road wheels, so that this brake can no longer impose severe strains upon the shafts and gear-wheels which transmit the power, from the gear-box, to and through the live-axle. There are thus two sets of brakes acting direct on the hubs of the rear wheels, one pair being of the internal expanding type, and the other pair operating upon the outer face of the same brake-drums. The arrangement of these brakes is clearly shown in Figs. 1 and 2, the former giving an excellent idea of the operating rods with their compensating devices, while the latter enables the brakes them-

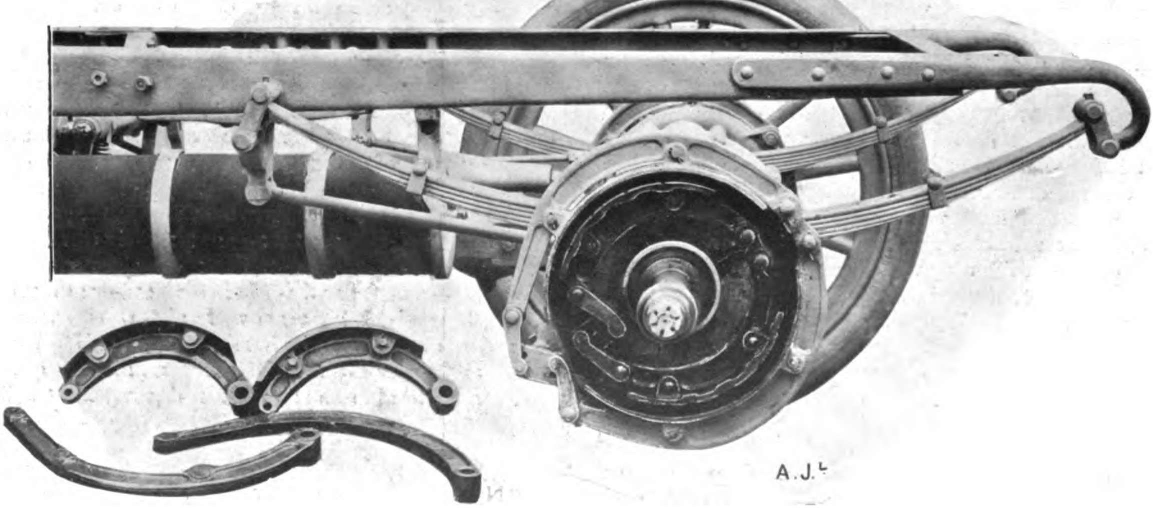

Fig. 2.—Side view of the 18-h.p. "National" Chassis, showing the rear portion, with the near-side wheel removed. The foot-operated, internal expanding brake is seen inside the hand-operated brake that acts upon the periphery of the same brake-drum. Also included in this illustration are a pair of internal, and a pair of external, brake-band-levers, the former having their renewable brake-shoes fitted to them.

---

* [An illustrated description of the engine appeared on p. 179 of our issue of February 11th, 1905, and a general article dealing with the construction of the chassis was given on July 23rd, 1904, pp. 871 and 872.—ED.]

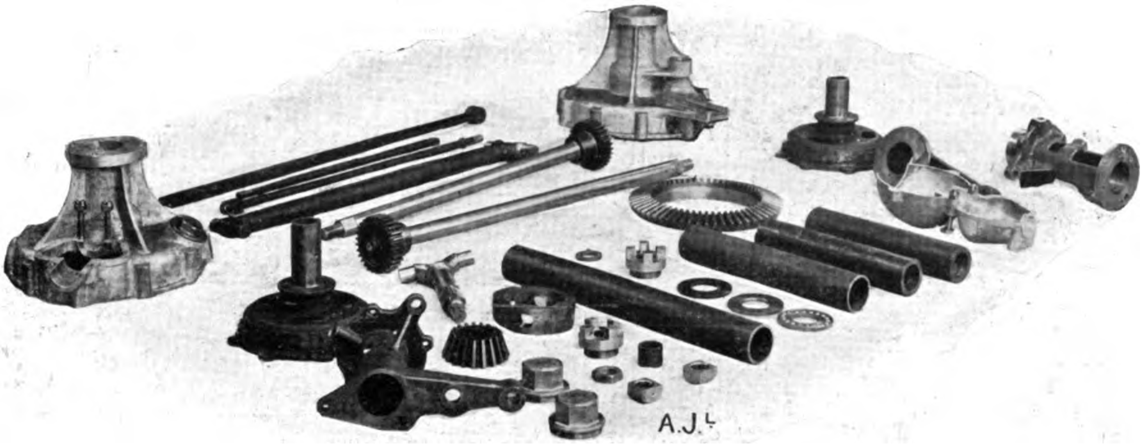

Fig. 3.—The chief component parts of the "National" "live" rear-axle, with its universally-jointed propeller-shaft, and the bevel-wheels that drive it.

selves to be seen. In Fig. 2 the road wheel, together with its brake-drum, has been removed, leaving the entire brake mechanism intact upon the chassis, while in the same illustration are included separate views of a pair of internal brake-strap levers, fitted with their renewable shoes, and a pair of external brake-strap levers with their shoes removed. Both brakes are of similar design, one end of each brake-strap lever being pivoted, and the other ends being connected by short links with crank-pins on the operating rock-shaft.

The same illustrations show the manner in which the short radius-rods are fitted between the side members of the frame and the spring-brackets on the axle-casing. In Fig. 1, the torque-rod that passes forward from the axle is also visible, but a word of explanation is required because in that view, it unfortunately appears to be hinged at its front end to the rock-shaft which controls the foot-brakes. As a matter of fact, it passes beneath that rock-shaft and is attached, with cushion springs above and beneath, to a hinged bracket beneath the cross-member of main-frame. At its rear end it is fixed rigidly to the casing that encloses the differential-gear and the bevel-wheels driving the axle. Other characteristics of this well-designed, and substantial, chassis will be noticed in Figs. 1 and 2, including the pressed-steel frame with its under-frame for the engine and the gear-box, the propeller-shaft with its neatly enclosed universal-joints at each end, and the long semi-elliptic side springs, lying between the frame and the road wheels.

Very great care has been taken in the design and construction of the live-axle—that most important part of any car of this type. It is built up in much the usual way, with steel tubes to enclose the revolving shafts, with a two-part casing about the central gear mechanisms, and with external stays beneath to take the bending strains. The road wheels run upon the outside surface of the stationary portion, thus relieving the shafts of the weight of the car, and the short shaft which connects the bevel-pinion with the propeller-shaft is supported by an additional bearing behind the bevel-pinion itself. Most of the component parts of the axle are shown separately in Fig. 3, and amongst them will be noticed the propeller-shaft, as well as one of the neat rings that form the simple universal-joints; in this type of universal-joint, the pins project outwardly from the two shafts, and the surrounding ring is made in two parts so that it can be made to receive, and form bearings for, the pins. Other parts which are prominent in Fig. 3 are the jaw-couplings by which the road wheels are connected to the "live" shafts.

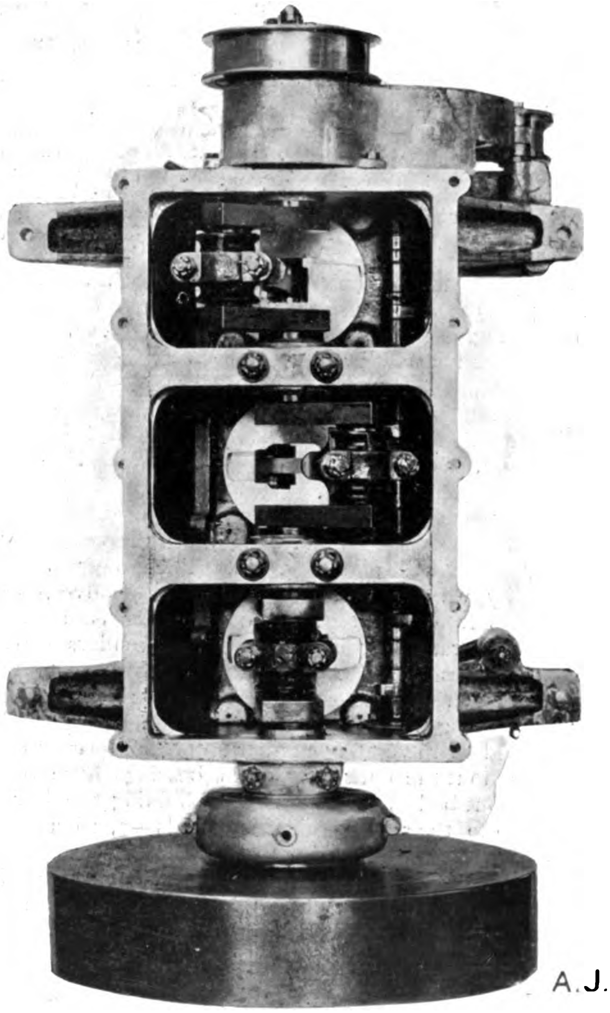

Fig. 4.—View, from beneath, of the 3-cylinder, 18-h.p. "National" engine, with the base of the crank-chamber removed. The crank-chamber is made in three parts, the base casting being quite independent of any moving parts, so that it can at any time be taken off for making a thorough inspection of the interior.

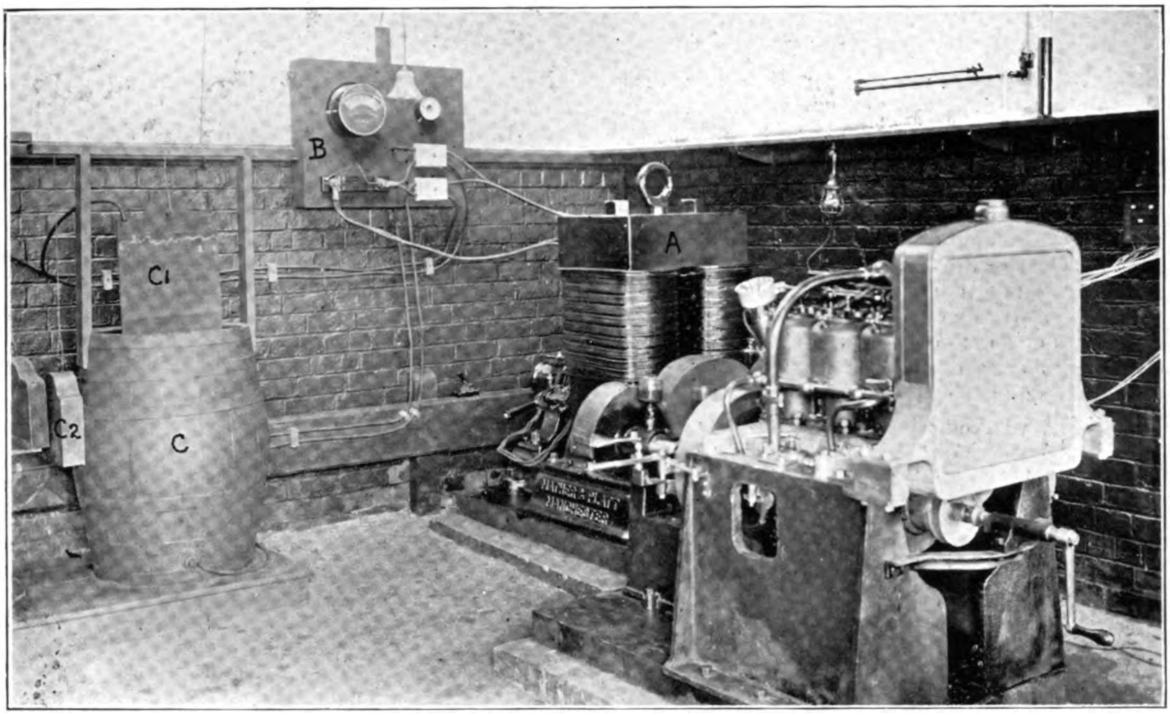

Fig. 5.—A corner of the test shop in Messrs. Rose Bros.' works at Gainsborough, showing a "National" petrol engine fitted up—with its own radiator, carburettor, and ignition coil—ready for testing. The power of the engine is measured electrically, the dynamo, A, being coupled up to it. From the dynamo the current is regulated by a simple water-resistance, consisting of the tub, C, the movable contact-plate, C^1, and the counter-weight, C^2, for balancing the plate, C^1; the metal plate can be immersed to any required depth inside the tub, thus varying the resistance in the electric circuit. From the readings of the ammeter and voltmeter on the instrument-board, B, the B.H.P. can at all times be calculated.

Fig. 4 is a view of the engine from beneath, the base-casting of the crank-chamber having been taken off. On the engine, the crank-chamber is made in three pieces instead of only two, and, therefore, the lowest portion is quite independent of all moving parts. The crank-shaft, with its four long bearings, and with the connecting-rods in place, is very well illustrated in this photograph, as also is the cam-shaft, up inside the chamber.

As now made, the engine gives 18-h.p. at a normal speed of 900 revs. per min., the cylinders having a bore of 4¼ in. and a stroke of 5¼ in. The power is controlled by varying the lift of the inlet-valves, the ignition is from batteries, the commutator is mounted upon a separate gear-driven shaft that renders it particularly accessible, the lubricator is subjected to the pressure of the exhaust-gases, and the circulating-pump for the cooling water forms a part of the engine itself, being fixed to the crank-chamber and being gear-driven.

Throughout the entire car, plain bearings have been adopted, but ball thrusts are used for holding the bevel-wheels up to their work. Three speeds—7, 16 and 30 miles per hour—are provided for by the gear-box, and a direct drive is obtained when the top speed is in operation. Usually the chassis is built with a wheel-base of 9 ft. 3 in., a track of 4 ft. 6 in., and is fitted with 870 mm. tyres, but it is also made with a 10 ft. wheel-base and with 875 mm. tyres for taking other types of body. In the former case the front and rear tyres are 90 and 100 mm. wide, respectively, and in the latter case they are 100 mm. and 105 mm. wide.

Engine Testing.

Very great care is taken to test the "National" engines in the works, under exactly the same conditions that they will subsequently have to run on the cars. For this purpose, the special arrangements shown in Fig. 5 have been made, this illustration being reproduced from a photograph taken in the test-shop. The engine is bolted down on the bed-plate, and is fitted with the actual radiator, carburettor, and ignition apparatus that are to be transferred with it to the chassis. It is coupled up, as seen, to the dynamo, A, and the current is led through the instrument-board, B, to the variable water-resistance, C. The load on the engine, as well as its speed, can be varied to a nicety in this way, by merely immersing the metal plate, C^1, to a greater or a less extent in the liquid contained in the barrel, C, for the amount of current that is allowed to flow through the electric circuit can thus be regulated to a nicety. At the same time, the power of the engine is indicated electrically by the instruments on the board, B. Every facility is consequently available for "tuning up" the engine properly before it is fixed to the chassis.

Royal Commission on Motor Cars.

On Tuesday last, the Royal Commission on motor cars held their thirtieth sitting. All the members were present. The following witnesses were examined:—Mr. G. G. Parkins, of Upper Holloway; Lieut.-Col. Fellowes, of Great Cumberland Place; Mr. H. Lucas and Mr. Johnson, of Messrs. Joseph Lucas and Co., Birmingham; and Mr. W. Hoare Ward, of the Weldhen and Bleriot Co., Ltd.

A MOTOR CAR ELEVATOR.

There must be many motorists whose private garages do not permit of a motor car pit, and as the necessity for occasionally getting under the car remains, it may be justly said that some form of portable elevator, such as that introduced by Adams and Co., of which we give illustrations, is well calculated to supply one of the motorist's much felt wants. Little explanation of the device is needed in view of the photographs, which clearly show its application. Simple channel girders form the two side members of the framework, which serve to guide the wheels of the car as it is being hauled up the incline (Fig. 1). Two winding drums, A, with adjustable handles, A^1, are fitted in order to enable the car to be drawn up into position by means of steel cables attached to the back axle. When the car is in place the whole frame of the elevator may be tilted up into a horizontal position, and supported by a trestle or box so that all parts of the chassis are as much accessible from beneath as they would be from a shallow pit.

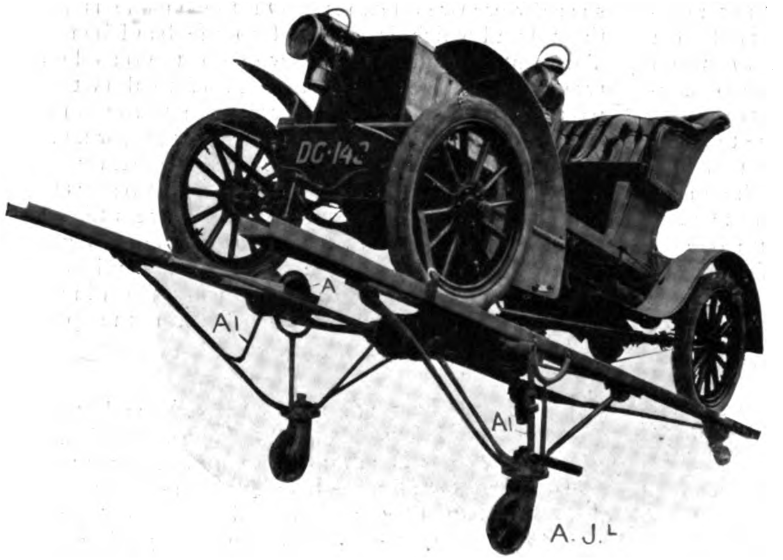

Fig. 1.—The Adams Elevator. View showing car on the Elevator when in an inclined position.

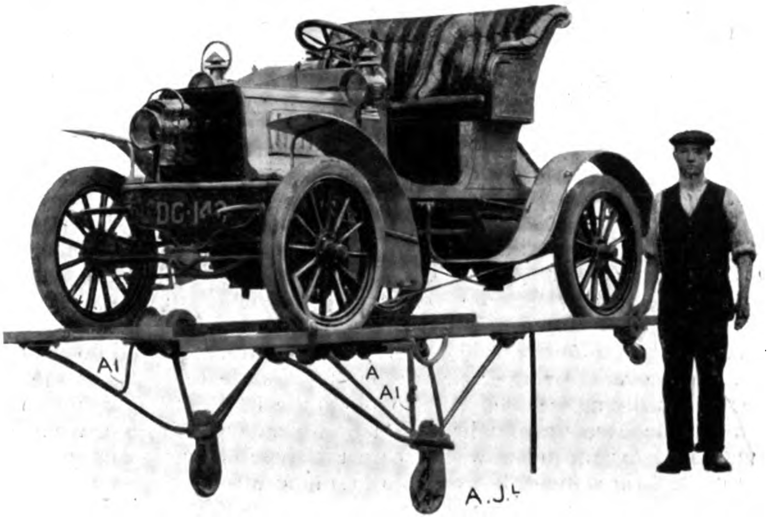

Fig. 2.—The Adams Elevator. View of a car in place after the Elevator has been tilted to a horizontal position. A trestle or box must be placed under the rear end of the framework to ensure security in this position.

It is not necessary, of course, to tilt up the framework in this way unless desired, because stout straps are provided for lashing the car in its inclined position. While so placed the machinery under the front portion is even more accessible, seeing that it is higher from the ground, and it is also in a somewhat more convenient position for working since there is not very much head room beneath the car when the elevator is horizontal.

As the width between the wheels of cars varies considerably, the elevator is made adjustable in this respect by means of a transverse screw and telescopic tie-rods. Being mounted on wheels, it is possible to move the car, when on the elevator, bodily from place to place, or to use the elevator as a turntable. When closed, the gauge is 3 ft. 5 in., when opened it is 5 ft. 2 in. The head-room provided for is 2 ft. 9 in., and the length of the channel 12 ft. Thirty feet of wire rope is provided on the drums, and the incline up which the car must be drawn is 1 in 3.

* * *

Effect of Motor Omnibuses.

There has been so much competition amongst motor omnibuses, particularly on the Cricklewood route, which seems to have been specially favoured by them, that various reductions have been made in the fares. One of the companies recently has reduced what was previously a 3*d.* fare for a $6\frac{1}{2}$ mile distance to 2*d.*, and the same Company has further lengthened the penny fare from Cricklewood by about half a mile. An interesting result of the improved communications to Cricklewood which the motor 'bus services have provided, is shown by the rapid filling up of much new house property in that suburb.

Progress in Australia.

In a communication received by the British Empire Motor Trades' Alliance, Limited, from the *Sydney Sunday Times*, it is interesting to learn that there are already some 500 motor cars running in Sydney and suburbs, and nearly 1,000 altogether in New South Wales. The New South Wales Government and sundry private companies are also establishing motor 'bus services. There are also about 400 motor boats on Sydney Harbour and the adjacent waters, and the New South Wales Motor Boat Club possesses about 140 active members. Evidently the automobile industry has been undergoing much the same rapid development in Australia as in this part of the world.

THE PULLMAN NON-SKID BAND.

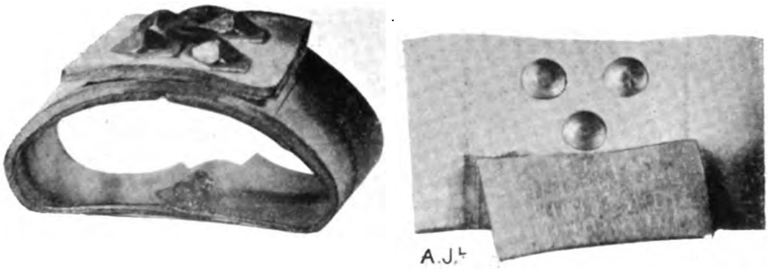
Few firms have such a well-established reputation in the manufacture of hard-wearing leather goods, even in England, which is notable for this work, than Messrs. Pullman, and that they should have turned their attention to the manufacture of a non-skid band is itself a matter for congratulation among motorists, to whom these things are of considerable importance.

In appearance the non-skids made by this firm are similar to the many other makes on the market, but there are one or two smaller differences in detail of construction, which are worthy of notice, and are well illustrated in our photographs. On the light-weight bands the rivets are inserted from the inside, and the hardened-steel nuts are riveted on the projecting ends. This allows the rivet heads, which are on the inside, to be smooth and flat, so that when covered by their protecting strips of leather they are hardly noticeable. It also allows the steel nuts to be made exceptionally hard and durable. On the bands used for the heavy-weight cars, this type of rivet is not used throughout, but only down the centre row. The other rows are formed by rivets which have pyramid-shaped heads on the outside, and their shanks are bifurcated, and riveted over on the inside.

Each band is formed by three separate strips of specially-prepared leather. On the outside is a fairly thick tread which is attached to the band beneath it. This central band covers the whole of the outside of the tyre, and its edges are chamfered off to allow them to pass over the beading of the tyre, so that, when in place, they are well under the rim of the wheel, which thus prevents the ingress of water between the leather and the outer cover. This is an important point because, even with very perfect vulcanising, there is always the chance that a tiny portion of the edge may come unstuck, and, if this is exposed, it is liable to collect dirt and moisture, which works its way in, thus destroying the adhesion of the remainder of the band. Beneath the principal leather band is another strip of leather which protects the inner ends of the rivets from the tyre.

Apart altogether from the excellence of any band in itself, there is also the manner of its fixing to be taken into account; but even when both are perfect, there is still the driver of the car to be answered for, and no doubt many motorists would save themselves much inconvenience, and no little money as well, if they could ensure that their chauffeurs would always practise true automobile economy, by considering their methods of driving with relationship to the effects they obviously must have on the tyres.

The Pullman Non-Skid.—Photograph of a band after completing 4,000 miles.



Two views of the Pullman Non-skids, showing (on the left) the Steel-Studded Tread used on the heavy-weight bands. The view on the right shows the smooth-faced inner ends of the special studs which are employed on the light-weight bands.

* * *

Railway "Enterprise" and Its Result.

A curious situation prevails at Brondesbury, a suburb in the north-west of London, which has for many years been very adequately served by the trains of the Metropolitan Railway. Some time ago, as is now very generally known, competing lines of motor 'buses were started, and these have since grown to such efficiency that many residents have transferred their patronage to them. Lately the Metropolitan Railway have so reduced their service from the station just at the most important time of the morning for business men, that many of the remaining would-be passengers have also been perforce compelled to make their journey by road. If this move on the part of the Company is merely an oversight, we fear that the management may find itself in a similar predicament to the cabmen after their strike, who discovered, too late, that the greatest effect of their action had been to make the majority of their erstwhile patrons, who had been driven to the homely but useful 'bus, confirmed users of that ubiquitous class of vehicle. No doubt the motor 'bus owners are fervently uttering hopes that the dearth of trains may continue.

Cheap American Cars.

A report from the United States announces that the Ford car makers are this year marketing a 12-16-h.p. 4-cylinder car at £100! Ten thousand is to be the year's output, and for 1907 this number is to be doubled.

AUXILIARY PETROL TANKS.

Devices for Preventing a Car from running short of Fuel on the Road.

MANY motorists have at one time or another experienced the annoyance of being stranded on their cars in the open country with their petrol tank empty and with many miles between them and the nearest source of supply, while even more cautious drivers must now and again have wished that there were some device on their cars that would save them any anxiety on that score. Some owners of cars have even gone the length of having a second tank fitted to enable them to carry an emergency supply, but as often as not the desired effect is cancelled in practice by habitually leaving both cocks open, while even if the auxiliary supply has been scrupulously kept in reserve, the petrol is apt to become stale and almost useless by the time it is urgently required.

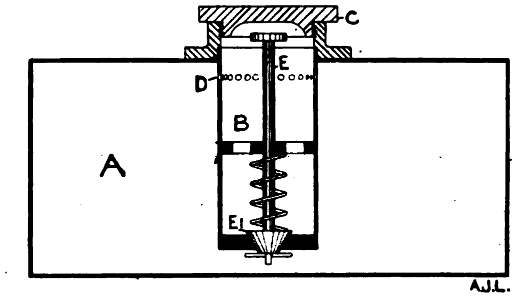


FIG. 1.

Our diagrammatic drawings show three alternative arrangements, all of which give equivalent results, the main features of Messrs. Soames and Langdon-Davies' invention being that the reserve supply is renewed with fresh petrol each time that the main tank is refilled, and that some definite act is necessary on the part of the driver before the auxiliary supply can be used. In all these illustrations the letter, A, is employed to denote the main tank; B denotes the auxiliary reservoir; C represents the filling cap; D indicates the overflow from the reservoir to the main tank; and the letter, E, is used for that portion of the mechanism which enables the auxiliary supply to be fed into the main tank. The device shown in Fig. 1 is equally applicable either for gravity feed or for pressure feed to the carburettor, while that represented in Fig. 2 is more especially intended for a pressure-feed system, and that in Fig. 3 is particularly applicable for gravity-feed.

Referring to Fig. 1, it will be seen that the reservoir, B, lies immediately beneath the filler-cap, C, inside the main tank, A, and that the row of holes, D, allows the petrol to flow over into the main tank as soon as the smaller reservoir has been quite filled. When, subsequently, all the fuel has been drawn off from the main tank, the auxiliary supply will remain in the reservoir, because, under ordinary circumstances, there is no other comunication between the two tanks than that through the holes, D. But it will also be noticed that a valve, E^1, is arranged in the bottom of the reservoir, B, and that this valve can be opened by means of the rod, E, which lies inside the cap, C. Thus, it is only necessary to remove the cap, C, and raise the valve, E^1, in order to transfer the reserve supply of petrol into the main tank. It is neither possible to remove the valve, E^1, bodily nor to leave it open, so that this device is practically proof against carelessness of any kind.

In Fig. 2, the filler, C, may be fitted some distance away from the tank, and the large connecting pipe, C^1, enters the top of the reservoir, B—which, in this case, is formed by a partition at one end of the tank, A. The only connection between the reservoir, B, and the main body of the tank, A, is through the pipe, D, which passes from the bottom of the former to the top of the latter. There is, however, a vent pipe, D^1, which is led from the top of the tank, A, to the filler cap, C, and this allows the air to escape when filling the tank. For filling, the entire cap, C, is removed; the petrol which is poured in then flows into the reservoir, and—as soon as the reservoir is full—the petrol overflows into the main tank. When, afterwards, the pressure in the tank has fed the main supply of fuel to the engine in the usual way, the reservoir, B, still remains full, and this auxiliary supply can only be utilised by first transferring it into the main tank. By the device adopted for this purpose, it is unnecessary to remove the filler cap, C, the only operation required being that of pumping air into the reservoir, B. This is done by removing the small cap, E^2, and attaching

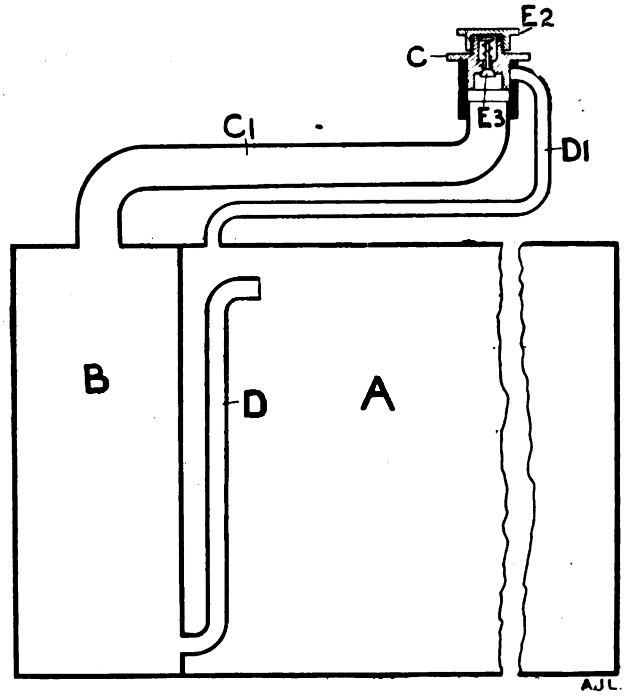

FIG. 2.

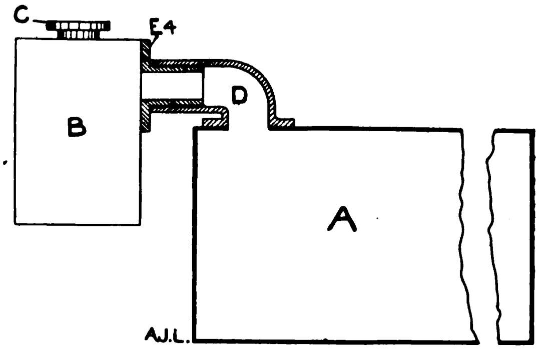

FIG. 3.

an ordinary tyre pump to the threaded nipple, when air can be forced through the valve, E^3, until the petrol is displaced from the reservoir, B, into the tank, A. As will be seen, the filler cap, C, closes the vent-pipe, D^1, and thus prevents the pumped air from entering direct into the main tank—an arrangement which is obviously essential.

In certain cases this device even enables the pressure to be retained in the tank while transferring the auxiliary supply of fuel from the reservoir to the tank, but on most petrol cars, of course, the pressure would be lost through the carburettor immediately after the main tank became empty. It will, too, be recognised in connection with this design that, if it is used for a gravity-feed system, the vent-pipe, D^1, would have to be replaced by an ordinary vent orifice communicating with the atmosphere.

Comparatively little need be said in order to explain the device shown in Fig. 3, for in this instance the reservoir, B, is quite distinct from the tank, A, and is merely connected to it in such a way that it can be turned upside down and its contents emptied into the tank through the swivel-joint (or gland if required), E^4, and the pipe, D. The reservoir must, however, be turned the right way up for filling the tank, since the filler-cap, C, is fitted in its upper face, and it is consequently impossible to fill the main tank without first filling the reservoir. It goes without saying that the connecting pipe, D, may be of any required length, but that it must enter the upper portion of the reservoir.

All these three variations of the same idea are remarkably simple, and are therefore likely to be adopted by many makers in the near future. At present, the designers are bringing their invention before the notice of automobile manufacturers, with the object of arranging with them to employ it on their vehicles.

THE RENAULT PATENT—INTERESTING DEVELOPMENTS.

There seems to be a probability, which has increased since we first referred to the subject, that we shall before long see a fight in the English Law Courts on the direct-drive question. As our readers will remember, the Renault Company of France are the proprietors of a British patent, which they consider will, if found valid, enable them to obtain royalties, damages, or an account of profits from all makers, sellers, or users of cars in this country who employ a gear-box which gives a direct-through-drive in combination with a live-rear-axle.

When referring to the matter before, we pointed out the essential need under such circumstances of combination amongst British manufacturers, who are in such case likely to become defendants. The need for such combination, however, is now superseded, since the Society of Motor Manufacturers and Traders announce that they will defend all proceedings taken against manufacturers, and that they have obtained counsel for the purpose. If the Renault Company or their supporters, therefore, are well provided with funds, there is a probability that we may before long witness an interesting and, technically, at any rate, highly instructive automobile patent case being tried in our Courts, which will have more interest for automobilists than any case that has been heard since the well-known Maybach carburettor action was fought some five years ago.

At any rate, if it comes off, there would be a fair fight and no favour. Whatever may be the outcome of the litigation, the Frenchmen can rely on absolutely fair treatment. The British Court of Chancery is perfectly unprejudiced and probably the fairest institution in the universe, and the judges, either in the Court of First Instance, in the Court of Appeal, or in the House of Lords, who are called upon to give their decisions, will decide the issue absolutely on its merits, on the evidence placed before them, and without even a suggestion of the bias which might in some countries possibly arise owing to the patent having originated abroad. That is one of the things of which Englishmen have a right to be proud. Our legal arrangements are far from ideal. They are much too expensive, and much too dilatory, but our judges of the Court of Chancery, the Court of Appeal, and the House of Lords, move in an atmosphere in which prejudice or partiality, at any rate, is unknown.

As regards the action of the Renault Company in France, it may be of interest in this connection to chronicle that some ten motor car manufacturers have, as the result of the action which has already been tried there, agreed to take licences from the Renault Company, and that the royalties the company fixed have been ½ per cent. per chassis for 1906 cars, and 1 per cent. per chassis for subsequent years. Of course, the provision has been introduced—as all good lawyers would insist on being done—to the effect that the licensee shall only be bound to pay the said royalty as long as the present decision of the Courts remains unreversed.

Thirsk Starts Motor 'Buses.

A new service of motor 'buses has been established in the Thirsk district, and the first vehicles were at work on the 8th instant. The Surveyor of the Rural District Council, who evidently does not like them, has reported that they are "making sad havoc" of the Ripon Road.

Continental Exhibitions.

In the absence of Prince Henry of Prussia, owing to the lamented death of the late King of Denmark, the Berlin Exhibition was opened on Saturday last by the Duke of Ratibor, in the Art Exhibition Building. About 340 exhibits are staged, but, as at Paris, there is nothing of any moment to record, bearing in mind the display of 1906 novelties at Olympia.

On the same day, the Turin Exhibition was inaugurated by the Duke of Genoa, officially representing His Majesty the King of Italy.

Motor Cars for Gold Mines.

The importance of the motor car for getting to a new goldfield which is off the line of railways, is being evidenced at present to the north-east of the Nevada Goldfield, where a new Eldorado, a camp called Manhattan, is said to have been discovered. Within a week the population of this mining camp has grown from 20 inhabitants to 4,000, and would-be gold-diggers and claimants are offering as much as £50 a day for the hire of motor cars to get them in time to jump their claims.

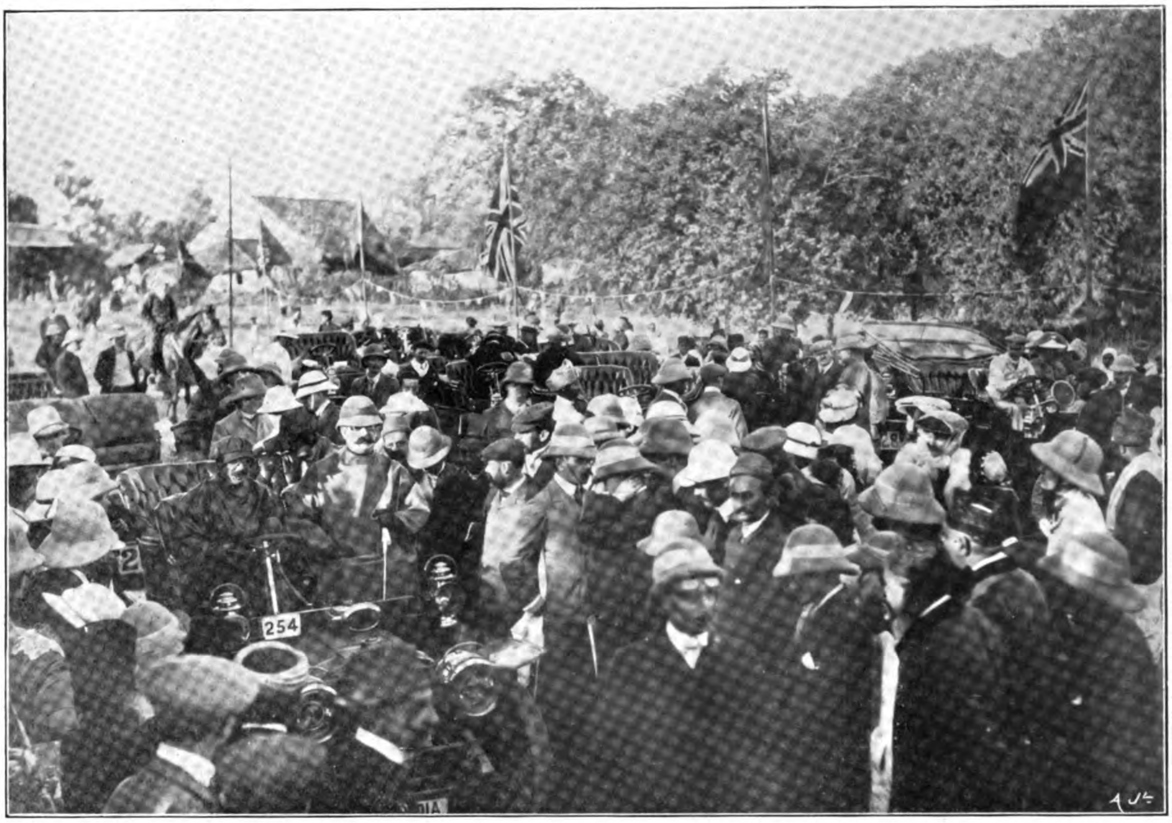
RACES, RECORDS, AND TRIALS.

INDIAN MOTOR TRIALS.

Somewhat more than twelve months have elapsed since the Motor Union of Western India inaugurated their very successful trials between Delhi and Bombay—an event in which, it will be remembered, no little interest was taken in this country. Now they have repeated the event, this year between Bombay and Mahableshwar, and with gratifying success. No less than thirty-seven cars left the starting-point on their first day's run to Poona, and throughout the whole 116 miles of the course traffic was suspended, except for military purposes, while the cars passed by. Interest among the natives there was in plenty, but of so curious a character that many of the motorists were not a little surprised at the effect of the appearance of their cars. So far from exhibiting any excitement, the inhabitants of the various villages, who had turned out *en masse* to witness the event, merely stood awe-struck and silent as the cars passed on their way.

On arrival at Poona all the cars were parked in the grounds of Mr. Jeejeebhoy's bungalow, half an hour being allowed for washing them down. There had been no incidents of note during the run, many of the cars arriving without losing any marks, although five did not turn up within the time limit. Mahableshwar was the second day's goal and the turning point of the whole run. It is only 75 miles distant from Poona, but the road, although good, is not easy, for it runs over the Katraj, Khandalla, Wai, and Panchgani Ghats, the latter especially being very long and difficult, winding its rising course around the hills for a distance of over 12 miles. In spite of these "obstacles," however, some of the cars again made non-stop runs, and few of the competitors had anything to complain of except punctures.

For the return journey a regulation was made respecting the passage through the tunnel at the summit of Katraj Ghat, this having proved a source of danger to motorists owing to its dim light, and the clouds of dust raised by the first few cars. For this reason, therefore, each competitor was prohibited from entering the tunnel before the preceding car had made its exit. At the very commencement of this day's run was the descent of the famous Satara Ghat, which, although really a very dangerous hill, was happily negotiated without accident. During the journey to Poona one of the three little 6-h.p. Wolseley cars—which are familiarly known among motorists in the country as the "Little Wonders"—unfortunately came to grief with a damaged gear. It is a striking testimony to the competing cars, however, when it is said that nothing more serious than this happened throughout the trials.



BOMBAY-MAHABLESHWAR TRIALS.—The scene at the Bombay starting point. The Richard-Brasier ready for the word to start.

By four o'clock on the following afternoon the cars were home again in Bombay once more, the actual control at Vincent Road being just a few miles outside the town. In the Class (D) for big cars, as we recently announced, no less than three cars tied, these being Mr. Sorel's De Dietrich, Mr. Khatau's Fiat, and the Paris-India Company's Richard-Brasier. They were, therefore declared joint winners, having each made non-stop runs. An agreement was entered into, by the competitors in question, by which the cup is to be inscribed

Maj. C. N. L. Meyer	10-12-h.p. Bayard	0
Paris-India Co.	10-12-h.p. Richard-Brasier	19
F. B. Stewart	10-12-h.p. Argyll	0
F. B. Stewart	10-12-h.p. Richard-Brasier	10
H. Sorabjee	10-12-h.p. Relyante	64
E. J. Lee	10-h.p. Clement	42
M. Ebrahim	10-h.p. Bayard	0
CLASS A.—*Cars costing £250 and under.*		
R. D. N. Wadia	8-10-h.p. Humber	12
C. M. Banaji	6-h.p. Wolseley	9
C. D. Kerrawalla	6-h.p. Wolseley	0

with a statement to the above effect. In Class B there were even more ties for the "Charles Harding" Cup, for the three Clement-Bayards, together with Mr. Lalkaka's Wolseley, and Mr. Stewart's Argyll all made non-stop runs. A similar agreement, as in Class D, as to the inscription of the Cup was entered into by the competitors, and the committee have voted a small silver shield to each as a memento of their success.

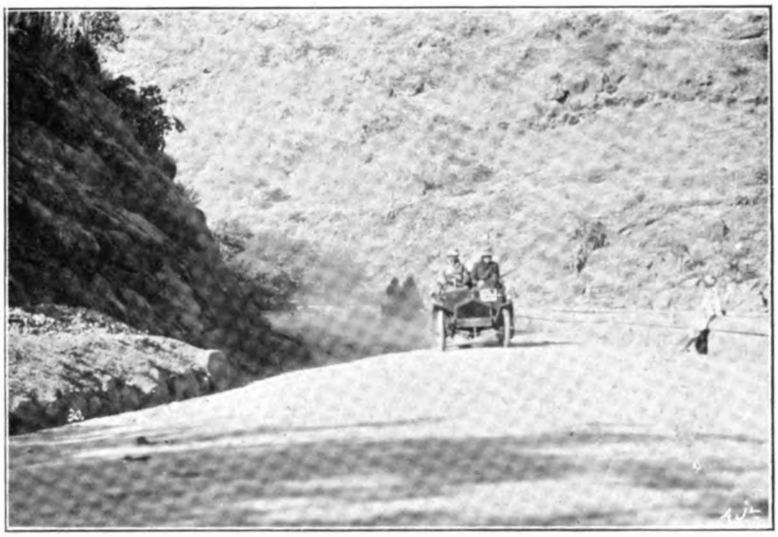
Dr. Deane's Argyll won the Challenge Shield in Class C, and Mr. Kerrawalla's 6-h.p. Wolseley the Union Cup in Class A. We annex a list of the competitors and the marks lost by them on the run.

A.C.G.B.I. Tyre Trials.

Relative value of the points to be taken into consideration in making the awards in the Tyre Trials:—

	Per cent.
1. (*a*) *Reliability.* — As shown by freedom from puncture (N.B.—From the 240 bad marks which will be imposed for each puncture or burst, 1 per cent. will be deducted for every minute occupied in repair or replacement less than 60 minutes) (*b*) *Durability.*—As shown by the running cost per ton-mile (N.B.—This cost will be made up as follows: Cost of outer covers and of inner tubes used or partly used, cost of repairs)	85
2. "*Yield and Return.*"—As shown by the "pile-driver"	10
3. *Other Points.*—Detachability, valves, security bolts, &c.	5
	100

Entries close on February 12th, at noon. Eleven firms have entered up to date.



BOMBAY-MAHABLESHWAR TRIALS.—The Humber Car, No. 33, on Wai Ghat, during the second day's run.

THE committee of judges appointed by the club for the trials of tyres, speedometers, and lamps is as follows:—

Ex-officio.—Hon. Arthur Stanley, M.P.; Mr. Alfred F. Bird, Sir Boverton Redwood, D.Sc., F.R.S.E.; Mr. Robert Todd, Col. H. C. L. Holden, R.A., F.R.S.

Mr. W. Worby Beaumont, Prof. C. Vernon Boys, Messrs. G. H. Baillie, Dugald Clerk, E. H. Cozens-Hardy, E. R. Calthrop, Major F. Lindsay Lloyd, R.E.; Messrs. A. G. New, Wilson Noble, Mervyn O'Gorman, Robert E. Phillips, Bernard Redwood, Earl Russell, Sir David Salomons, Bart.; Messrs. J. Lyons Sampson, A. A. Campbell Swinton.

Resilient Wheel Competition.

THE A.C. de France has accorded its patronage to this trial, which has been organised by our contemporary, *L'Auto*, and was announced in our issue of Jan. 13th. Under the modified rules there will be two classes, one for ordinary wheels shod with resilient tyres (pneumatics in contact with the road are excluded), and the other for spring-wheels in which the resilient medium is between the hub and the felloe. In each class there will be two categories.

The first is for vehicles having engines of not more than 314·16 cm^2 piston area, the total weight of the car with passengers and in running order to be not less than 1,500 kilogs. Luggage and spare parts for the wheel may not be included in this minimum weight. The second category is for vehicles which weigh (as above) at least 1,800 kilogs., and have engines of not more than 490·86 cm^2.

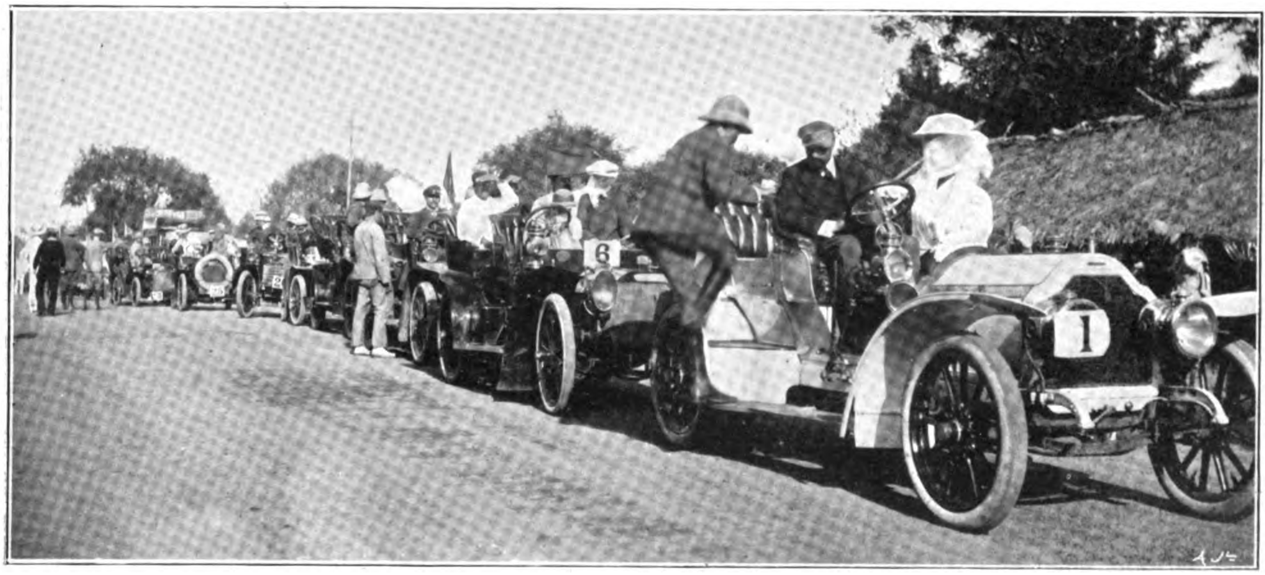
The entry fee for each vehicle is to be 100 francs, and the four wheels may only be fitted with devices of the same pattern. Entries will be received up to March 20th, 1906, and competitors must specify beforehand which parts of their device they wish to be allowed to change during the run, and how many times they will require the liberty. Drawings and models of the device must be submitted in advance.

Trials will be held over a distance of 2,000 kiloms. in daily stages of about 300 kiloms. Nine days will be allowed, which will give time for one day's rest, and for an exhibition if necessary. Closed "parcs" will be enforced throughout the trial; drivers may be changed, and each competitor must provide one observer for other competitors' cars. Repairs may be executed *en route* by those on the car with the tools carried by them, but an inclusive average speed of 30 kiloms. per hour must be maintained, otherwise the car will not be classed.

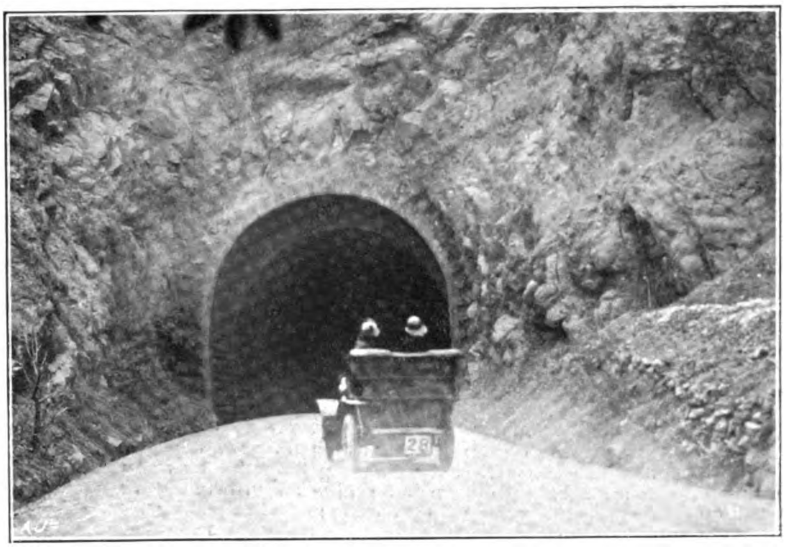
The competition will be held between March 25th and April 16th, 1906.

Swiss Industrial Vehicle Trial.

A TRIAL for commercial motor vehicles, entirely of Swiss manufacture, is to be held at Geneva, under the



BOMBAY-MAHABLESHWAR TRIALS.—Winners in the Contest.



BOMBAY-MAHABLESHWAR TRIALS.—The Clement Car, No. 29, entering the dangerous tunnel at the summit of Katraj Ghat, on the return journey during the third day.

auspices of the Swiss A.C. in April next. It is the first event of this character in Switzerland, and may possibly help to bring about a better feeling in the country towards automobilists. There will be two classes, viz.:—(A) Motor omnibuses, (B) Motor wagons and vans. Class A entrants will run over a distance of 435 kiloms., and Class B vehicles 341 kiloms., each spread over four days, with an exhibition of the competing machines at Berne on April 25th.

Milan to San Remo.

A COMPETITION for voiturettes between these two points is announced to take place from April 2nd to 8th next. There will be three classes, viz.:—

Cat. A.—Three or four-wheeled voiturettes, under 250 kilogs. weight, with one cylinder of 1,000 cc.

Cat. B. — Four-wheeled voiturettes costing, with carriage body, under 4.500 francs.

Cat. C.—Four-seated voiturettes costing, with carriage body, under 8,000 francs.

In every case not less than two riders must be in each vehicle. "Teams" of three cars of the same make will have a special cup for competition.

MOTOR CYCLING.

Land's End to John-o'-Groat's Trial.

AT the last meeting of the sub-committee of the Auto Cycle Club appointed to consider this matter, the following programme was drawn up for this Trial:—

First Day.—Leave Penzance, 7 a.m., for Taunton, via Land's End, Launceston (Lunch). Total 151 miles.

Second Day.—Leave Taunton, 8 a.m., for Warrington, via Worcester (Lunch). 201 miles.

Third Day.—Leave Warrington, 8 a.m., for Locherbie, via Kendal. 140 miles.

Fourth Day.—Leave Locherbie, 8 a.m., for Pitlochrie, via Stirling (Lunch). 155 miles.

Fifth Day.—Leave Pitlochrie, 8 a.m., for Tain, via Inverness (Lunch). 136 miles.

Sixth Day.—Leave Tain, 8 a.m., for John-o'-Groats, via Wick. Arrive John-o'-Groats, 3 30 p.m. 112 miles.

The time schedule has been worked out on a basis of minimum speed 15 m.p.h., and maximum speed 20 m.p.h.

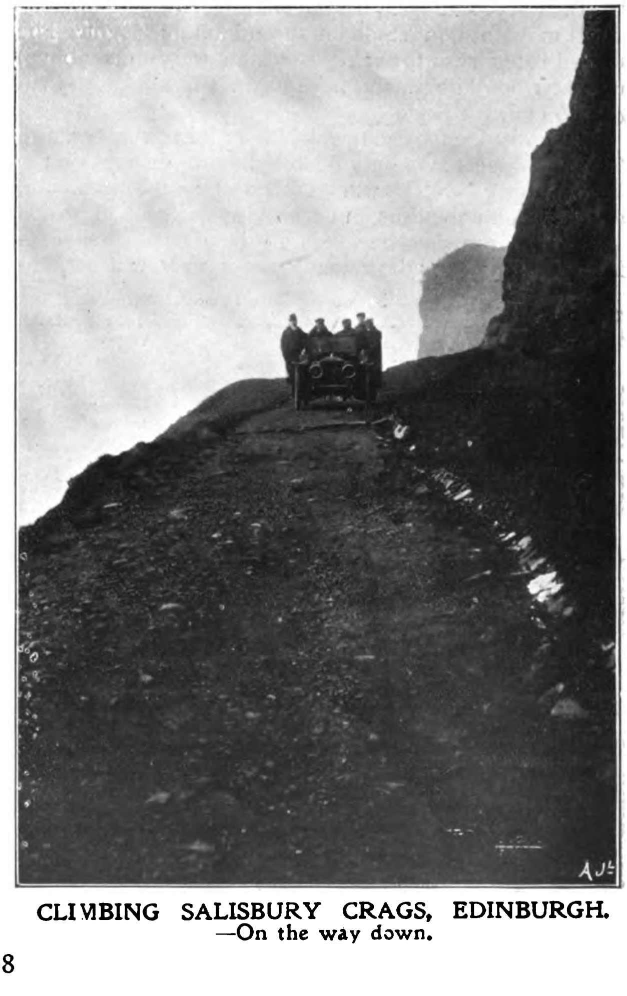
The Trial is to start on Monday, 11th June, and be open to all classes of motor cycles. This Trial is to take the place of the Annual Six Days' Trial, and no other long distance events will be held during 1906. Entrance fee, Five guineas first machine, Three guineas each additional machine to manufacturers; private owners, one guinea; members of Affiliated Clubs, 15*s.*; and of the A.C.C., 10*s.*

International Cup.

THREE challenges have been lodged with Austria, the holders of the Cup, for this year's contest, viz., by Great Britain, France and Germany. The date and place fixed for the event are June 29 in South Bohemia. For the British eliminating trials three machines are already assured, viz., two from Messrs. H. Collier and Sons, of Plumstead, and one from Mr. C. B. Franklin.

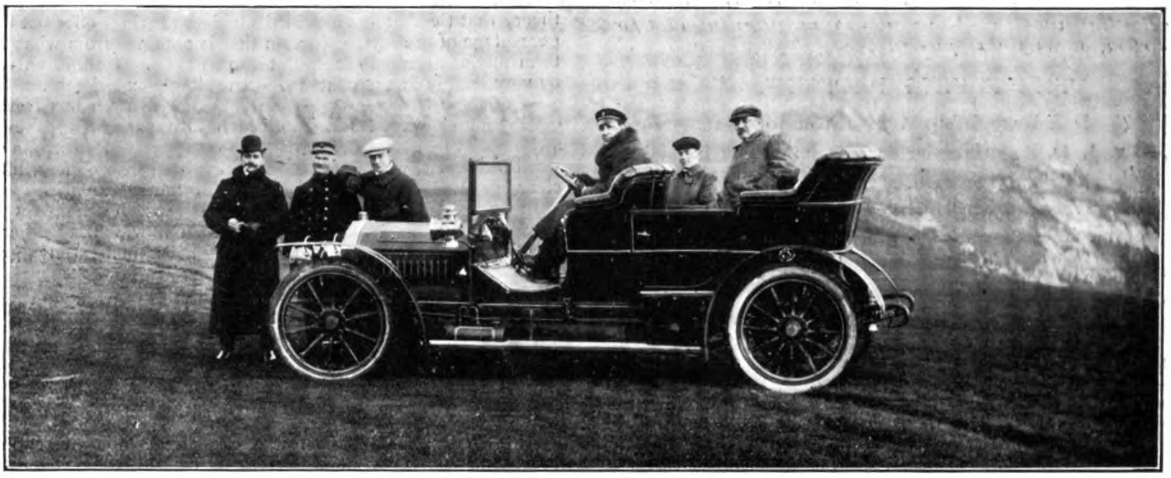
French Events.

IT has now been decided to run the Motor Cycle Club de France international championship events for motor bicycles only (30 and 50 kilogs.), to which we drew attention last week, in May next, the "Criterium du Motocycle," which embraces motor tricycles, tricars, and quads up to 250 kilogs. weight, being relegated to June.



CLIMBING SALISBURY CRAGS, EDINBURGH. —On the way down.

CLIMBING SALISBURY CRAGS, EDINBURGH.



CLIMBING SALISBURY CRAGS, EDINBURGH.—Mr. Charles Jarrott and his 22-h.p. Crossley Car at the point where he started for his climb up the Crags.

Very briefly last week we mentioned the climbing, by Mr. Charles Jarrott on his 22-h.p. Crossley car, of the famous "Radical Road" up the Salisbury Crags at Edinburgh. We have now received a series of photographs of the event, which we reproduce this week, and the following pithy account of the feat from *The Scotsman* gives some further points in regard to the performance, and shows the estimation in which Mr. Jarrott's climb is held in the Scottish capital. The task, Mr. Jarrott mentions, was a difficult one, particularly by reason of the fact that the ground was exceedingly soft and offered no holding for the tyres. The path itself was an ugly one and very slippery, and at spots on the ascent deep gullies led to the sheer cliff, where faulty steering would have meant a drop of from 800 to 1,000 feet.

The Scotsman writes:—"Motoring on the 'Radical Road.'—The path—for it is little more—which skirts the base of the Salisbury Crags and is known as the 'Radical Road,' is about the last road in the vicinity of Edinburgh where one would expect to encounter a motor car, but Mr. Charles Jarrott, the well known motorist, yesterday afternoon accomplished the feat of driving his car to the highest point of the road, turning and bringing it back again in perfect safety. The car was a 22-h.p. Crossley, and it carried six passengers.

"The gradient in places appproaches 1 to 4, and there are bits of the road where it required the most skilful steering to prevent the car from overbalancing. The climb was made from near where the flag post denotes the entrance to the 'Hunters' Bog,' as approached from the Albert Gate, and it was in itself no mean feat to get the car on to the track from the drive.

"This is believed to be the first time any vehicle has traversed the 'Radical Road.'"

Likewise the Cadillac.

A similar performance was also undertaken and successfully carried through by Mr. F. S. Bennett on an 8½–10-h.p. Cadillac car. Mr. Bennett travelled up the "Radical Road" and descended the rocky face of the Cragside to Holyrood Palace—a remarkable feat in view of the low horse-power of the Cadillac car.

Mr. Bennett's return journey did not follow the same route as that of Mr. Jarrott, it will be noticed, and if there be any difference between the two descents, the palm for difficulty lies with that leading to Holyrood Palace. It is said that no vehicle has ever before made the ascent, and if the tradition has any truth in it, then it is very fitting that the automobile should be the first to reach the top, for if the conquest of the hill had to wait for a still more perfect form of road locomotion to be evolved, it would probably remain "untracked" for a very long time to come.

CLIMBING SALISBURY CRAGS, EDINBURGH.—Commencement of the descent.

CORRESPONDENCE.

⁂ *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion, or containing queries.*

THE FLYING PROBLEM.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Mr. J. D. Roots is under a wrong impression in thinking I have overlooked the difficulties of starting from and alighting on the ground with an aeroplane, for it is quite reasonable to suppose that an aeroplane cannot be supported in the air with a wind velocity of much less than 20 m.p.h. passing under its surface, and I gather this is Mr. Roots' chief objection. Although this appears to be a difficulty at first, I think eventually it will be overcome in a satisfactory manner. One thing, it is desirable that an aeroplane for general use should be mounted on four wheels for simplifying starting and alighting.

On a calm day, when there is little or no wind about, a bird will arrest its motion, as Mr. Roots states, by turning its tail downwards, but when there is a wind, it does not necessarily do this, for with its wings outstretched it will gradually reduce its speed until it is comparatively stationary a few inches above the ground, when it will suddenly close its wings and step on to the ground. So should there be a breeze of, say, 20 m.p.h., then it is possible to alight with practically no momentum, and also a start from the ground against this breeze could be made with only a very slight forward motion, as the Wright Brothers have done.

But one of the difficulties, if this can be called one, is when there is a calm, then the required speed must be obtained by moving the machine along by its own propeller; on alighting, it is a simple matter to turn up wind-resisting surfaces and so check the speed, or, on the other hand, say the machine alights at a slight angle and at a speed of 20 m.p.h., this momentum could be quickly arrested by applying the brakes to the wheels.

I hardly agree with Mr. Roots' statement that "an aeroplane will only be usable, whatever the success and skill eventually attained with it, in a treeless and houseless country." There are many spots in and around most towns where departures and arrivals could be made by motor-driven aeroplanes, should they be a success and become general; surely landing and departing places on open spots will be quickly made, namely, clear and smooth-surfaced spaces.

Certainly it is a very desirable feature to be able to rise straight up, but it appears to me that if this is done on a calm day it must entail a great expenditure of power.

With reference to the eagle and the albatross experiencing difficulty in rising from the ground, it all depends if there is a wind; the former can rise easily in either case, whereas I have only seen the albatross rising in the wind, which it does when on the sea by facing it, and on reaching the crest of a wave it outstretches its wings, the wave passes on leaving the albatross floating on the air. But should the albatross find itself in St. Paul's Churchyard, it would, I should say, simply flap its wings in the orthodox manner, whereas, on the other hand, if it had a sufficiently light and powerful motor, it could, by outstretching its wings, be propelled out either in a spiral form or in a straight line up one of the roads.

I quite agree with Mr. Roots that a commercial aerial machine must carry passengers with the same degree of safety as the train and the motor car. I hope the future will prove the aeroplane not only to be the quickest but safest means of locomotion.

Yours faithfully,
Putney. A. V. ROE.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Mr. J. D. Roots, in this week's issue, has very happily brought the albatross into the discussion centreing on aeroplanes, and of a surety the albatross, if he could only speak, could tell us much concerning this subject.

It has been my fortune to spend many a happy hour watching these birds, leaning over the poop rail of a sailing ship travelling at a moderate speed; I have seen a huge bird appear right astern, come up on the quarter about a hundred yards off, take out his clutch, and then without one single flap of his 17-ft. spread of wing, circle round the ship, and finish up at the place where he started, let in his clutch again for half-a-dozen reciprocations, and continue the manœuvre *ad infinitum*.

According to the ordinary accepted laws, in order to keep a body afloat in the air—that is of a greater specific gravity than this fluid—work must be done either by this body falling or by the reduction of its initial velocity. But in the case of the albatross it certainly did not fall, as it was only a few feet from the water at the commencement, so the work must have been obtained through the inertia source, but although I repeatedly endeavoured to observe this, I could never notice any diminution of speed.

This, I have come to the conclusion, can be explained by the theory that the feathers of a bird's body and wings offer but a small percentage of the surface friction that is obtained from what I may term any artificial substance yet known to us. I think this could be very readily demonstrated by some simple experiment.

With regard to the suggestion that the albatross has trouble in getting under way, I have noticed he always accomplishes it by swimming to windward, and as he tops the crest of a wave, a downward beat of his wings, and a good kick from his web feet, lifts him clear, and he is soon going at the rate of knots.

In alighting, say to pick up some scraps, he makes a spiral descent, and finishes by an upward sweep, which, together with outstretched feet, bring him to rest in a moderately graceful manner.

Yours faithfully,
Ipswich, February 3rd. ARTHUR F. EVANS.

CAR INSPECTION.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—With reference to the interesting paragraph which appeared on page 105 of your issue of the 27th January to the effect that the manager of a motor company has arranged for a periodical examination to be made by an inspector of engineers of every car sold by him, it may interest you to know that we some time since decided on this policy, and that at the present time one of our 8-cylinder cars is touring the Kingdom with an inspector from our works on board, who is making a thorough examination, gratis, of every Rolls-Royce car—2-cylinder, 3-cylinder, 4-cylinder, 6-cylinder and 8-cylinder—which has been sold by us, and we are glad to report that this experiment has proved not only to be a great satisfaction to the owners of cars, but also a great instruction to us, as by this means we have been able to effect small adjustments which were naturally overlooked by an unskilled mechanic, or amateur owner of a car, and have—as acknowledged by the latter—made considerable improvements in the running of our cars.

These tours of inspection are arranged to take place periodically.

Yours faithfully,
C. S. ROLLS AND CO.,
Geo. H. Malton, Managing Secretary.
February 1st.

TRIALS OF RESILIENT WHEELS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—As one closely connected with motor traction, I have read the accounts of the recent 4,000 miles Reliability Trials established by the Automobile Club of Great Britain and Ireland with keen attention.

That power-driven vehicles are destined, sooner or later, to supersede animal traction upon our roads is admitted on all sides. How soon or how late this consummation will arrive depends solely upon the evolution of the practical, economical, vibration-absorbing wheel.

The Automobile Club has once more earned the gratitude of all who are interested, directly or indirectly, in the new but already vast movement of which it is the acknowledged head, by initiating these competitions, but it appears to be a matter of regret that when inaugurating these exceedingly valuable tests, the club committee did not go a step further and set forth more clearly the only conditions under which, in their opinion, it is possible to definitely determine the actual vibration-absorbing qualities of any particular wheel offered for trial.

It certainly appears to be very hard upon the inventor or proprietor of any spring wheel, that after pluckily incurring all the labour, anxiety, and heavy expenses which these official trials involve, he should be told by the judges, at the conclusion of the 4,000 miles run, that his performance has practically demonstrated nothing. Yet this is apparently what has actually happened in the case of the reliability trials of the two spring wheels which have alone, up to now, had the courage to offer themselves for public trial, owing to the fact that both these spring wheels were furnished with solid rubber tyres on their outer periphery.

I observe in the certificate of performance in a 4,000 miles long-distance trial of the Middleton pneumatic hub wheels, published in *The Automobile Club Journal*, Vol. XI., No. 194, page 40, the judges emphasise the fact that this wheel "may be run with a deflated tube . . . . and that the fact that it is deflated is not readily detected by those riding in the car." They continue: "This points to the importance of the part played by the solid rubber tyre in connection with this device," and they suggest that "the true way to test the efficacy of the pneumatic hub would be to try it in conjunction with iron tyres."

The same remarks might obviously have been made with equal justice and equal reason in regard to the other set of spring wheels, the Hallé, which underwent a similar trial.

Such a test as that proposed by the judges would indeed be severe, almost to the point of brutality, but would at least have the advantage of leaving no room for doubt in the public mind as to how much of the vibration-absorbing qualities claimed by any particular wheel is due to the old device of a solid rubber tyre and how much is due to the new device introduced by the inventor.

The first man who designs and builds a set of spring wheels with steel rims or treads capable of carrying a car of say 2 tons over ordinary English country roads, *averaging* 20 miles an hour (which would necessitate occasionally attaining a speed of 30 miles an hour) will have gone far towards solving perhaps the most pressing mechanical problem of the day.

Yours truly,
CECIL EDGE.

February 5th.

FOUR CYLINDERS AND SIX CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—The suggestion which Mr. Johnson makes on behalf of Messrs. Rolls and Company is a good one; but I think the jury of "unconverted" persons which he proposes is open to the objection that so much could be done to hoodwink them by an expert driver. I would sooner see the jury composed of men who are alive to all the "tricks of the trade."

I do not think that further correspondence will do anything to settle the relative merits of the two types of engine. The proof of the pudding is in the eating, and the "eating" is best done on the road.

The bore and stroke of the Sunbeam car which I propose to use are 95mm. and 120mm. respectively, and the normal engine speed is 1,000 revolutions per minute. My wheel base is 9 ft. 7 in.

I shall be pleased to meet any 6-cylinder car of similar power in a contest such as has been proposed. We shall begin to learn something then.

Yours faithfully,
T. EASTMEAD.

February 1st.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—We note under the heading of "4-cylinder versus 6-cylinder" a letter from Mr. G. Smith.

In his letter Mr. Smith says that Mr. Edge must be perfectly well aware that there is no such thing as an up-to-date 40-h.p. Mercedes, as they do not make this model for 1906.

We should like to point out, in order to prevent any misunderstanding, that the 45-h.p. 1906 Mercedes, fitted with direct drive, ball bearings to engine, &c., takes the place of the 40-h.p. 1905 model, and the 35-40-h.p. 1906 model takes the place of the 28-32 1905 model.

Yours faithfully,
For Ducros Mercedes Limited.
H. DU CROS, Managing Director.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I am sorry to see that Captain Deasy, after making a challenge on behalf of the 4-cylinder car, which I accepted with a 6-cylinder, has now withdrawn, because my 6-cylinder Napier is too fast.

When I accepted the challenge I appreciated that on the speed question I should beat him, and that is why I suggested further tests of silence, hill-climbing capabilities, &c., but as even on these points he does not think that the 4-cylinder would be superior, I am willing to leave the matter in the position he has left it, namely, making a challenge, and then refusing acceptance in accordance with the conditions that he himself laid down.

Yours truly,
S. F. EDGE.

February 1st.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I note that Captain Deasy expresses in the Press the hope that a match may be arranged between a 6-cylinder car and his own 4-cylinder car. I am pleased to inform you that, on the 31st ult., when I informed Captain Deasy that I could arrange for one of C. S. Rolls and Company's 6-cylinder cars to be run against his 4-cylinder car, provided that the result should not rest purely on speed, but that the advantages which are claimed for the 6-cylinder car over the 4-cylinder car should also be taken into consideration, he generally agreed to the proposal. I think I may safely say, therefore, that we may look forward to a very interesting trial between a car driven by four cylinders and a car driven by six cylinders.

As the trial is likely to be of interest to your readers, I trust that you will permit us to communicate to you for publication suggestions concerning the form of contest, as it is possible that your readers may help Captain Deasy and myself to arrive at the best form of competition.

I wish, at the outset, to state that in the design of the 6-cylinder Rolls-Royce motor car, the desirability of obtaining the highest possible car speed out of a given piston area was not viewed as the primary consideration. This question was, of course, specially studied in the construction of the Rolls-Royce Tourist Trophy cars. In producing the 6-cylinder cars however, a difference in speed of a few miles per hour has been considered as being of little importance as compared with absence of engine vibration, smoothness of retardation and acceleration without declutching, removal of the necessity of changing gears, absence of shock, and silence.

The suggestion which I have placed before Captain Deasy, for his kind consideration, are, that the contest take the form of a reliability trial run on the high roads at the legal speed, with the additions of speed tests on hills and on the flat to be held on private roads; the jury, consisting partly of automobile experts and partly of private owners, to be divided into two halves, which would change cars at mid-distance, and would ride on each car during the speed tests; the jury to give records of the superiority of one car over the other as regards speed on the hills and speed on the flat, and to give opinions as to the superiority of one car over the other in respect of each of the points above-mentioned. As from a rough calculation it appears that Captain Deasy's 4-cylinder car has a piston area of 487 sq. cms., while the 6-cylinder Rolls-Royce has a piston area of 468 sq. cms., the match should be extremely interesting, especially if Captain Deasy will accept the suggestion that the total weight of the cars, together with passengers, should, by means of ballast, be made the same, and that the area presented to wind-resistance, should, so far as possible, be made identical in both cases.

I am, Sir,
Yours obediently,
CLAUDE JOHNSON.

February 2nd.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I notice a somewhat curious statement made recently in your paper by a correspondent who was trying to uphold the 4-cylinder principle against the six, and one of his arguments was that the 6-cylinder engine had 50 per cent. more parts than the 4-cylinder.

The statement appeared to me so far from the truth that I had the actual facts got out and the engine of a well known make completely taken to pieces, and all the parts carefully tabulated and counted, and I find that the parts in a 4-cylinder engine number 776, and that the increase on a similar powered 6-cylinder is less than one quarter.

Perhaps your correspondent would not mind now giving information as to why he made such a wild statement. I have all my papers carefully tabulated so that he can check them if he so desires. I think it will come as rather a surprise to many people that the 4-cylinder principle, which they have been upholding as of such great simplicity, should consist of 776 separate and distinct pieces, and it will now be clear to them why the 6-cylinder engine will wear so much better than the four, as, owing to the very even turning motion, the large number of pieces that are necessary in a multiple cylinder engine have the shock on each part so reduced by the Napier 6-cylinder principle.

Yours truly,
S. F. EDGE.

February 1st.

A PROPOSAL AND A CHALLENGE CUP.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—It has struck me, in connection with the forthcoming match between 4-cylinder and 6-cylinder cars, which is at present being arranged between Mr. Claude Johnson and myself, that although this match will no doubt be interesting in itself, the result may not be absolutely conclusive as to the respective merits of four or more cylinders. I have therefore decided to offer a cup, valued 100 guineas, to be called the "Deasy Challenge Cup," for a competition, to be run under rules the general principles of which are briefly outlined below.

I trust that the Automobile Club will see their way to take this matter up, as I believe the competition will not only be of great interest, but exceedingly useful to the automobile world.

If no better opportunity is available, I would suggest that the competition take place in the Isle of Man, at about the same time that the Tourist Trophy is held.

Yours truly,
H. H. P. DEASY.

February 6th.

Proposed Rules for the "Deasy Challenge Cup," value 100 Guineas.

1. The competition to be under the control of the A.C.G.B.I. Distance to be not less than 150 miles, nor more than 250 miles.

2. To be confined to *bona fide* touring cars of standard types, as usually sold to the public, and with a limitation of power, as in the "Circuit Européen."

3. Cars of three cylinders, or any number above, to be eligible, provided the total piston area of all the cylinders does not exceed the total maximum area of four cylinders, as defined by the rules of the "Circuit Européen."

4. Minimum weight and minimum standard dimensions to apply to chassis and bodies.

5. Minimum load to be five persons, and about 150 lbs. of luggage, or the equivalent.

6. The race to be open to the world.

7. The winning car shall be that which completes the course in the shortest time; but the record of petrol consumption, speed on the level and on hills, gear ratio, weight, and other features which are likely to be of interest to automobilists, to be published.

8. The cup to be the absolute property of the *entrant* who wins twice in succession or three times in all.

SIX-CYLINDER *v.* FOREIGN CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I have read with interest the various discussions in your late issues of the four *v.* the 6-cylinder and the British *v.* the foreign cars. Having had a 6-cylinder Napier put at my disposal by Mr. S. F. Edge, and also an inspection of the 6-cylinder under construction at the Napier works, I am certain one can only realise the various advantages of the 6-cylinder over the four by close inspection of the internal parts of the engine, and by the way Mr. Cecil Edge put the 6-cylinder car to various tests which I suggested. This is where the British manufacturer is showing his heels to the foreigner. I do not think it worth while for agents in this country representing foreign cars to try and make the public doubtful as to whether the foreign car is in any way superior to the British manufactured car. It may be the agents for the foreign cars are feeling the effects of the sale of the British cars and the way the public are preferring the British to the foreign car, or it may be because the foreigner is not manufacturing a 6-cylinder car, which I believe I am right in stating; but I do not hesitate in saying there will be only one more Olympia Show, or there may not be even one before the public will see the foreign agent at the shows, opening the bonnet of their foreign cars, and there you will see the 6-cylinder engine. I was much amused in one letter, the writer stating that it was a good thing for the British industry that foreign built cars have been imported freely into this country, as the English constructors have had set before them the finest products of Continental factories to test, copy and criticise. This, in my mind, is where the British manufacturers have been put to a great disadvantage, as they had only one market for their produce, and in this one market they had to compete against the whole world, wherefore the foreign manufacturer has had the advantage of two markets (one protected for themselves), and so being in a position to lay down a large factory with a big output, and thereby putting them in a much better position to experiment with the profits of their larger output, whereas the British manufacturer had a smaller output, and had to compete with the foreign cars in their own market. I think this can easily be proved by the way some of the British firms have been financially in very low water in years passed; now the principal experimenting is over, and the British manufacturer is put on a little fairer competition with the foreigner, and has now put on the market a 6-cylinder car, and if the foreigner follows in the Britishers' footsteps by placing 6-cylinder cars on the market, I think I am quite right in saying that British manufacturers can claim themselves to be the leading motor manufacturers of the world, and in answering this time only will tell.

Yours faithfully,
J. PERCY DEAN.

February 5th.

Developments in the Edison Cell.

THE Edison cell has been re-modelled once again. The solemn announcement is made that the existing types are liable to lose capacity. This is the official recognition of what has all along been an open secret, a secret so open, in fact, as to have had no little effect in keeping the Edison battery out of commercial employment. We refer, of course, to the peculiarity that out of a particular number of cells installed for any particular purpose, say in an electric car, a certain number, it may be five, ten, or fifteen, out of fifty, would lose capacity without apparent rhyme or reason. Boiling, it has been said, restores their capacity, but boiling accumulator cells is not a nice operation to undertake. It is now claimed for the Edison battery that a new method of construction has got over this difficulty. The positive plates of the old cells, it will be remembered, were constructed of bricquettes of nickel oxide enclosed in perforated sheaths of nickel-plated sheet steel. This type of structure has now been abandoned or at any rate replaced by a tubular arrangement, the positive plates consisting of a number of vertical perforated tubes connected together in a grid, the nickel oxide being arranged inside the tubes. It is claimed for this arrangement that the loss of capacity referred to is completely eliminated. The truth of this contention obviously depends on the correctness of the assumption that the loss of capacity was really due to the alleged cause, *i.e.*, diminished continuity between the active material and the supporting grid. It is by no means certain that this is the true explanation, and we shall consequently not be at all surprised to find that the Edison cell is still liable to unexpected loss of capacity. Let us hope, however, that this surmise will not be borne out in practice.

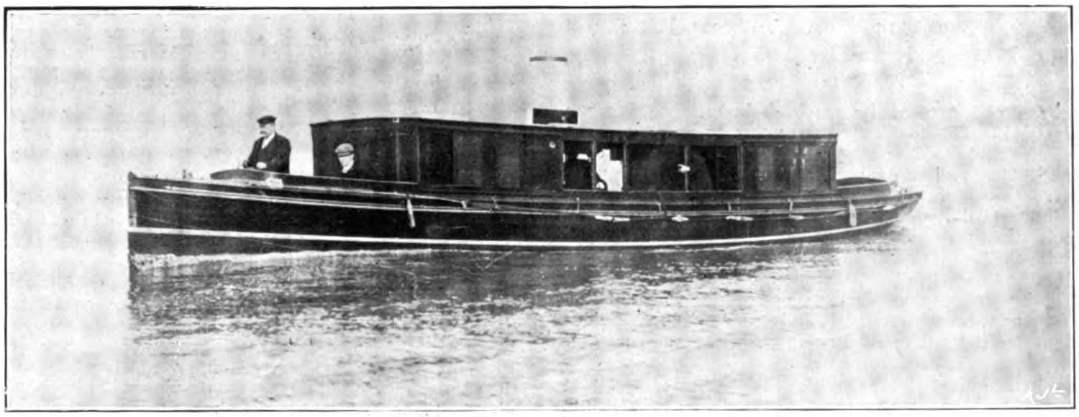
Transport in the Colonies.

THE need of transport, which, as we have on more than one occasion pointed out, is frequently such a terrible handicap to the development of out of the way mining districts, seems to be felt with special stress in the mineral zone of British Columbia. Extended use, it would seem, is made of aerial cables and glissades down mountain slopes (when snow prevails). The adoption of these methods is suggestive as regards the state of affairs prevailing. There is a crying need of heavy motor transport. But, just as in Matabeleland, as we have already pointed out, the advent of the motor will have to be preceded by the advent of the road maker, and the road maker will require a considerable amount of capital.

Cyclist v. Fowl.

A CASE in which the misbehaviour of a fowl on a public road resulted in damages against its owner instead of for him, as is the usual occurrence, is reported from Axminster. An eccentric pullet flew out of a house just as a school attendance officer of Colyton was passing on his bicycle. Sudden contact with the fowl threw him over and damaged his bicycle, and a County Court judge gave judgment for the plaintiff, saying that people ought to learn to exercise proper "control over their stock, whether it was cattle, pigs, or poultry," and, *we* should like to add, children. In fact, the new Parliament would deserve the thanks of the community by passing a law which should make it punishable for parents to imperil their children's lives by allowing them to use the high-road as a playground.

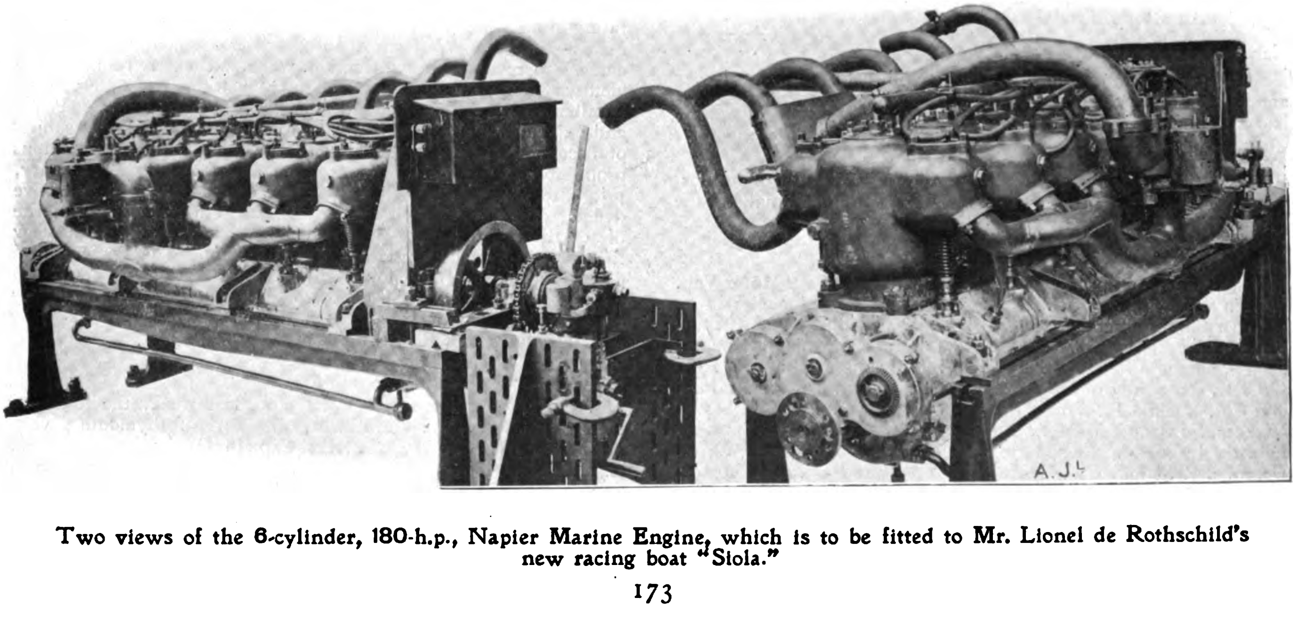
MOTOR BOATING.



A 55-ft. Thornycroft Motor Boat, built for the Governor of Nova Goa (Portuguese India). The boat is particularly roomy and has cabins fore and aft, the engine, a 6-cylinder 6 ins. by 8 ins., developing 78 b.h.p., being placed amidships. Paraffin is used as fuel. During a recent test the boat attained the satisfactory speed of 12 miles per hour, and is now on her way to Marmagoa. The principal dimensions are as follows:—Length, 55 ft.; beam, 8 ft.; draught 3 ft. 6 in.

Mr. Lionel de Rothschild's 180-h.p. Napier Motor Boat "Siola."

THE powerful 6-cylinder engine for Mr. Lionel de Rothschild's racing boat, "Siola," has now been completed, and we are able this week to reproduce two excellent photographs that clearly show its construction. It is essentially a marine motor, and has each cylinder formed by a separate casting, so that this engine is, to only a limited extent, designed on the same general Napier lines as the 60-h.p. car engine of which we gave a fully illustrated description quite recently. Its inlet-valves and exhaust-valves are of the same size as one another, but they are arranged symmetrically on opposite sides of the cylinders, with high-tension ignition-plugs fitted above the former. The induction-pipe is, moreover, designed with the object of rendering all the inlet-valves precisely equidistant from the carburettor, but it lies beneath the carburettor instead of above it, and the warm-air supply-pipe passes across above the cylinders. In spite of the enormous cylinder dimensions—8-inch bore by 5-inch stroke—the engine runs at a normal speed of 1,250 revs. per min. Special provision is made for protecting the valve-springs from salt water, all these springs being enclosed (though not so shown in our illustrations) by aluminium cases. Other features of this huge engine are the hollow nickel-steel crank-shaft, with bearings between each pair of cranks; the same type of oil circulation from a gear-driven pump as on the new 60-h.p. car engine, in addition to a pressure-fed drip-feed to the main bearings and a hand-pump to the crank-chamber; and the admission of water from the gear-driven pump into the jackets immediately around each exhaust-valve. Although the engine appears to be quite easy to start by hand—by the use of a prising bar—a 4-h.p. motor is fitted to it, as seen in the photographs; a disc clutch, and a double reduction gearing are interposed between the small single-cylinder engine and the large engine. Overall, the dimensions of this 180-h.p. machine are as follows: Length, 7 ft.; width, 2 ft. 2 in.; and height, 3 ft.



Two views of the 6-cylinder, 180-h.p., Napier Marine Engine, which is to be fitted to Mr. Lionel de Rothschild's new racing boat "Siola."

CLUBS AND ASSOCIATIONS.

A.C.G.B.I.

On Thursday, February 15th, Dr. W. Watson, F.R.S., will read a paper on "The Use of the Engine as a Brake."

Aero Club.

The club has now purchased a special balloon (about 50,000 cubic feet capacity) for the use of members; this balloon, built on the most modern and up-to date principles, is fitted with new type valve, rip cord, &c., and will accommodate four or five persons, according to length of journey, &c.

In addition to the balloon committee, it has been decided to form a technical committee on aerial locomotion, whose chief functions will be to advise the committee of the club as to the best means of encouraging and promoting in Great Britain the study and invention of machines of the heavier-than-air type, to organise competitions for aeroplanes, engined and otherwise, and to draw up the rules and regulations for the Salomons Prize. Also to examine and report on inventions submitted to the club.

It has been decided also to form a meteorological committee whose principal function will be to promote and carry on the scientific research of the higher atmosphere by means of meteorological observations and experiments from balloons and kites.

The Fédération Internationale Aéronautique has appointed the Aero Club as the recognised body representing aeronautics in the United Kingdom.

The next Annual Congress will take place at Berlin during the summer.

Aero Club Aeronautical Exhibition.

The Aero Club are organizing an Exhibition of aeronautical appliances, balloons, models, pictures of balloons and flying machines and other objects of aeronautical interest in connection with Messrs. Cordingley's Motor Car Show at the Agricultural Hall from March 24th to 31st.

The Secretary of the club will be glad to hear from any person who would be willing to exhibit or lend articles of interest. The club are prepared to defray the expense of carriage to and from the exhibition, and every care will be taken of articles lent or exhibited.

A prize of £10 in cash will be awarded for what in the opinion of the Committee is the best model or other exhibit in the Exhibition. Any further particulars can be obtained from the Secretary of the Aero Club, 110, Piccadilly, W.

Automobile and Cycle Engineers' Institute.

We learn from the Secretary of the Institute at Birmingham that at the request of those members of the Institute who are resident in or near London, it has been decided to form a London section of the Institute under the chairmanship of Lieut.-Col. Crompton, C.B.

The first meeting of the London section will be held on the 14th inst. at the Royal United Institution, Whitehall, London, and Colonel Crompton will read a paper on "Some Unsolved Problems in Motor Engineering."

This meeting will be an open one, and anyone interested can obtain a ticket for admission on application to the Secretary, at 109, Colmore Row, Birmingham.

Cardiff Motor Club.

At the first annual meeting of the club, held last week, it was announced that there is now a membership of 74, and the treasurer had a balance in hand.

Ladies' A.C.

"A Try for the Herkomer Trophy" is the title of an illustrated lecture which will be given by Mrs. Edward Manville at the Ladies' Club on February 22nd.

Motor Van and Wagon Users' Association.

The Association proposes to change its title to the "Motor Van, Wagon and Omnibus Users' Association," and now includes in its membership representatives of all the large trading and carrying companies. By way of example, the railway companies are represented, among others, by the Midland Railway, the G.W.R., the G.C.R., &c.; the carrying companies by Messrs. Carter, Paterson and Co., Messrs. Pickfords, &c.; manufacturing firms by Messrs. Vickers, Sons and Maxim, Stothert and Pitt, &c.; the brewing industry by Messrs. Bass, Ratcliffe and Gretton, Messrs. Watney, Coombe, Reid and Co., Messrs. Whitbread and Co., and Messrs. W. Hancock and Co., Ltd.; the milling industry by Messrs. Mark Mayhew, Ltd., Messrs. Whitworth Brothers, Messrs. F. Skurray and Son, &c.; and the omnibus companies by the Road Car Company, the London Motor Omnibus Company, &c.

In connection with the work of the Association, important new developments are in contemplation for the forthcoming year with a view to improving and securing the increased use of commercial vehicles. Particulars of the Association may be obtained from the secretary, Mr. Rees Jeffreys, 1, Albemarle Street, Piccadilly. Its membership is open to all firms using, or proposing to use, commercial motor vehicles, and any person interested in road transport problems.

North London A.C.

The joint committees of the Southern Motor Club and the North London Automobile Club have decided that the competition between the two clubs for the "Gamage" Challenge Cup shall take the form of a speed judging contest, to be held in May next, on the Bath Road. The North London Club announce a Cinderella dance, to be held on the 17th inst., at the Midland Grand Hotel.

Nottinghamshire A.C.

Mr. Charles Hardy, the president, occupied the chair at the annual meeting of the club on January 29th, when the report disclosed a substantial position, both as regards the balance of funds in hand and the membership, which stands at 166. Proposals were submitted by Mr. Barlow for the revision of the rules, making it impossible for any member concerned or "actively engaged" in the motor car industry to serve as an officer of the club. After a very animated discussion, in which it was contended that an arbitrary rule of this kind would do a grave injustice to members who were largely responsible for the inauguration of the club, it was rejected by an overwhelming majority. Mr. Charles Hardy was re-elected to the presidency; the vice-presidents chosen were Mr. E. W. Wells, Lieut.-Col. Birkin, Mr. B. W. Winter, Mr. G. H. Kirk, Mr. G. Cowen, and Mr. A. R. Atkey; Mr. Booth Granger was again elected hon. secretary and treasurer, with cordial thanks for his past services in these capacities; and the following were elected to serve on the committee: Dr. Hogarth, Dr. Buckley, Messrs. W. D. Wells, H. Rimington, J. J. Spencer, H. Belcher, M. Ross Browne, A. Barlow, W. D. Foster, and R. Cripps.

Society of Motor Manufacturers and Traders.

The offices of the Society are being removed to Maxwell House, Arundel Street, Strand.

The necessity for more commodious premises has arisen from the great increase in membership and the widening of the scope of the Society's work. The annual Exhibition is supplemented by general work for the protection of the motor industry. There are also sections dealing with commercial vehicles, marine motoring and components and tyres. The Society's new premises will provide a centre for its members where all motoring literature and works of reference will be at their disposal. A board room, capable of seating 200 persons, will be available for meetings.

Important Motor Trade Movements.

The Society of Motor Manufacturers and Traders, representing the British makers, have been specially active recently. They report that they have rendered assistance to the London Chamber of Commerce and other bodies in the Hunslet case respecting the rating of machinery. The Society also gave financial help in the case against the Western Road Carrying Company for special damage to roads by heavy traction, which ultimately resulted in a victory for the motor trade. The regulations respecting motor omnibuses, which are issued by the Chief Commissioner of Police and published by us in this week's Journal, have been the subject of discussion by a joint deputation of the Society and the omnibus proprietors, who laid their unanimous views before Mr. Henry, prior to his settling the various clauses. The prospective defence to the Renault patent claim to a monopoly on the direct drive for motors has been taken charge of with a view to protecting the interests of British makers. The Society have offered the Automobile Club a special prize for steam cars, to be competed for separately from petrol cars, in the Tourist Trophy race, and the important question of the petrol supply is now engaging the attention of the Society.

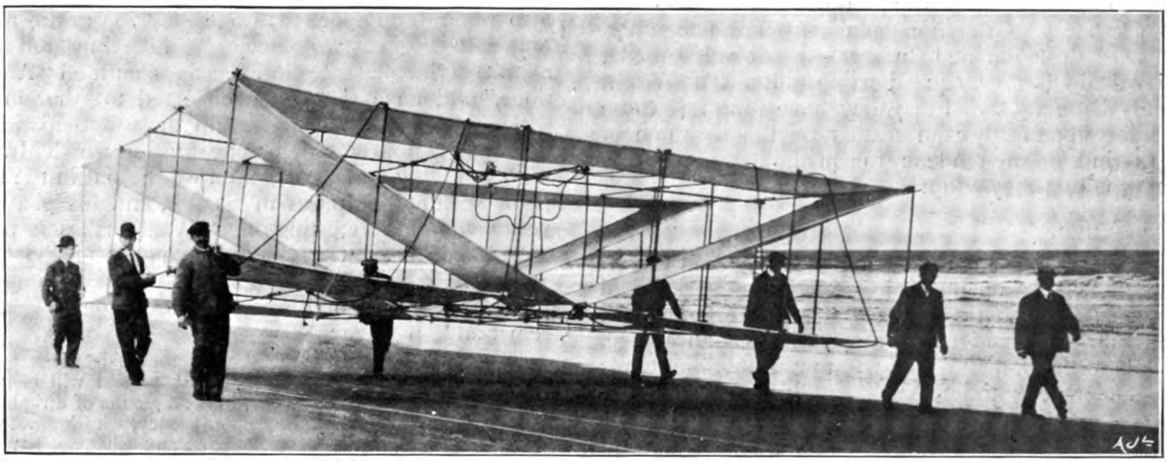
South Wales A.C.

At the annual meeting of the club, last week, the following officers were elected:—President, the Earl of Plymouth; vice-presidents, Mr. Godfrey L. Clark, Captain Hughes Morgan, Mr. C. H. Bailey (Newport), Mr. D. W. Graham (Ilston Park, Mon.), the Hon. C. S. Rolls, Mr. J. Colby (Boncath), and J. Thompson Willows; hon. treasurer, the Rev. Miles Whiteside; hon. secretary, J. Thompson Willows. The affairs and finances of the club were reported to be in a very satisfactory condition.

AERONAUTICS.

The Hamilton Aeroplane.

THE illustration which we give above, of a flying machine or aeroplane being marched along the Ormond-Daytona Beach, possesses a special interest of its own, as it shows the Hamilton aeroplane before it met with the very serious accident to which it fell a victim, though the aeronaut who was mounted on it escaped with great good fortune practically uninjured. We reproduce the photograph for several reasons. One of them is that we described the experiment and the resulting accident on the 27th of January last, and it may prove of interest to our readers to see how a machine, with which an actual experiment has been made, is constructed. It will be noted from the way in which the Hamilton aeroplane is held aloft by those marching it along, how light it is, and how it almost seems to float in the air, and this is the sort of thing that a photograph, and only a photograph, can show. There is, however, another reason why we reproduce the photograph. The arrangement of surfaces adopted in the Hamilton machine is, we believe, open to criticism. Of course, as we pointed out when referring to the experiments on the Ormond-Daytona Beach, and on other occasions also, it is very doubtful whether much can be learned from mere towing, which was being done with the Hamilton aeroplane when the accident occurred. We know quite well, and it has long passed out of the region of discussion, that an aeroplane, suitably shaped and driven by existing types of engines and existing types of propellers, will develop more than the necessary lift to maintain itself and a load in the air. That is no longer in dispute. It is in the manipulation of such machines successfully under *working conditions* that progress only has to be sought for, and it is in that direction only that progress is needed. We purposely emphasise the word "working" because towing experiments do not reproduce working conditions. The tow-rope provides not merely the motive power, but it provides stability as well. It is possible that the effects of rudders might be tested on a towed aeroplane to a certain extent, but only to a certain extent, and we question whether the knack of absolutely controlling the machine would in this way ever be learned at all. It may not at first sight be apparent to everyone how the tow-rope can give stability, but a moment's reflection will show that if at any moment the towed aeroplane tends to deviate from the definite direction which the tow-rope would give it, the tendency to restore it to that position goes on increasing and increasing till it is brought back to that direction. This is the exact opposite of the state of affairs that occurs when an aeronaut is controlling or attempting to control a free aeroplane, whether a gliding machine or a motor-driven one. The more he allows the machine to be deflected from its proper position, the more difficult would it be to get back into it, and it was this peculiarity of apparatus of the kind that was responsible for the deaths of Lilienthal and Pilcher.



The Hamilton Aeroplane being "marched" along the Ormond-Daytona Beach. It is with this machine that the experiments referred to on this page, and in our number of the 27th January, were carried out.

For the Sake of Criticism.

TOWING, therefore, provides no true test, and that brings us to the third reason for our reproducing the photograph, viz., for the purpose of criticism. We do not believe that the type of machine shown is ever destined to attain success in free flight without undergoing very considerable modification. It may act as a successful kite, in fact it has been proved to do so, but, as pointed out above, this is a very different thing from being a successful flying machine. Our views may be ultimately shown to be wrong. In a subject of such uncertainty, dogmatism is unwise, but the principles involved in the Hamilton aeroplane conflict with those which we are at present of opinion are the right ones. Even if subsequent experiment shows our views to be incorrect, we cannot avoid the belief that the science of aeronautics is likely to benefit from any *bona fide* criticism of the various types of machines proposed.

Why its Design is Open to Criticism.

IT will be remembered that the type of machine with which, in the first place, Mr. Chanute, and in the second place the Wright Brothers, have accomplished their successful glides, consisted of two aeroplanes, or, to be more correct, aerocurves, superposed and connected together by struts and ties on the lattice-girder principle. An attempt to improve this form of construction was made by M. Archdeacon in France, who adopted an arrangement of a similar nature, but added to it a couple of superposed aerocurves some distance behind it—the rear pair being rigidly connected with the front pair. This form has never been approved of, either by the Wright Brothers or by Mr. Chanute, the former holding the view that it diminishes the controllability, and M. Archdeacon's experiments with it, either for gliding purposes or when towed by boat, have been so unsatisfactory that we think the imperfections of this type of machine have been fully demonstrated. It is true that the Langley machine, a model of which executed a free flight of about a mile on the Potomac River, was built on these principles, but the results obtained with models (as has been pointed out often enough) are apt to be very misleading, and the Langley machine, as soon as built large enough to carry an aeronaut, made a signal fiasco of its only attempted flight.

Inclined Surfaces of Doubtful Utility.

SECONDLY, it will be observed that the Hamilton aeroplane, in addition to the top and bottom aerocurves, has inclined surfaces assisting in bracing the top and bottom surfaces of the horizontal aeroplanes together. The use of these inclined surfaces—the di-hedral angle, as it is called—is of very questionable utility. The Wright Brothers distinctly stated that they have found it to be satisfactory in perfectly calm weather, but that the moment there is wind, or any tendency to squalliness, it is inferior to the type that they adopt.

Other Faults.

BUT the Hamilton aeroplane does not adopt the di-hedral angle fairly and squarely. It sticks the inclined surfaces in between two horizontal surfaces, by which means they are deprived of their principal advantage. The idea of the di-hedral angle is that if anything tends to upset lateral equilibrium, such as a sudden gust of wind, if one side is lifted the tendency to lift on that side is diminished, while the other side is brought more horizontal. The pressure underneath it accordingly increases, and so there is a tendency to a restoration of equilibrium. This effect very largely depends on the inclined surfaces being free, and, as may be observed, in the Hamilton machine this is far from being the case. The diminishing upward pressure on say the left inclined surface as the machine tilts say to the right, is interfered with and diminished by the surface underneath it, while the pressure underneath the right-hand inclined surface, which should correspondingly increase, is prevented from fully doing so for precisely the same reason. At the same time the juncture of the surfaces forms solid angles at the sides of the machine, and data exist amounting almost to proof, that the presence of such solid angles is harmful. The apparatus, it will be seen, has neither a rear nor forward tail. There is nothing, as in the Wright machine, to raise or lower it, restore longitudinal horizontality if upset, or to enable it to turn either to the right or to the left so as to restore horizontality. These omissions suffice to show that the machine was and could only have been used as a man-carrying kite, to which the tow-rope supplied not only the lifting and propelling, but also the guiding force. Of course, it may have been that the experimenter intended to see what it felt like, up above, in a machine of the kind. But the absence of the controlling apparatus, to which we have drawn attention, is alone sufficient to explain the accident, if we merely suppose a little inattention or want of judgment on the part of the motorist towing. The experimenter had nothing in fact by which to control the height of his machine in the air, and the height to which it flew depended, of course in consequence, solely on the speed of the car and on the wind. If the motorist had been a careful man and, noticing that the aeroplane was going too high, had slowed down the car, nothing might have happened. But the aeronaut was at his mercy.

Whether our criticism is correct or mistaken, further experiment alone will show, but if it is found, as we believe it will be, that it is practically impossible to execute glides or free flight with a machine of this type, our views will have been shown to be correct. In any case, as we have previously remarked, we think little is to be learned from mere towing by a motor car.

A Prophecy and Its Realisation.

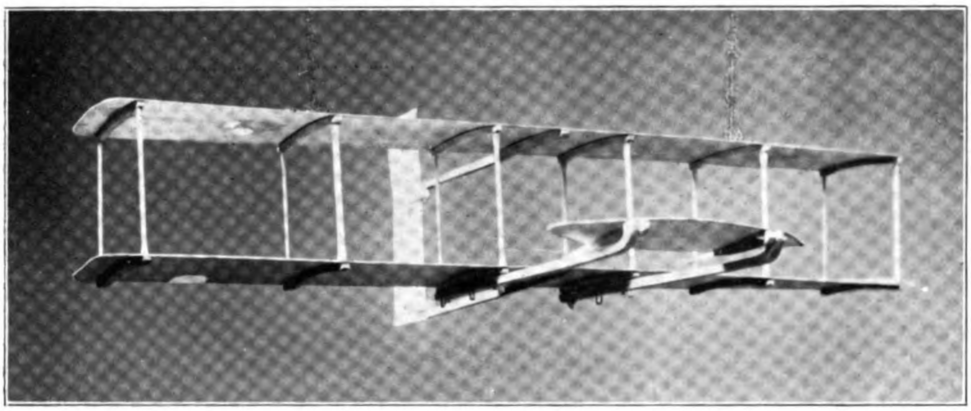
FROM time to time we have referred to the very pregnant suggestions relative to the future developments of aerial navigation put forward by Mr. H. G. Wells in his novels and imaginative tales of the future. We have also referred on more than one occasion to the remarkable collection of "prophecies" which appeared first of all as a series of articles in magazines, entitled "Anticipations," and have since been collected together in book form. It is noteworthy that in these anticipations the principal, if not the only practical use to which Mr. Wells seems to think aerial navigation will be put in the future, is for scouting purposes in warfare, and his picture is a very vivid and interesting one. What makes it particularly interesting is that since the chapter on the subject was written, one of the prophecies that it has contained has been already fulfilled. We refer to the following remarkable passage:—

> "I am inclined to think that the many considerations against a successful attack on balloons from the ground will enormously stimulate enterprise and invention in the direction of dirigible aerial devices that can fight. Few people, I fancy, who know the work of Langley, Lilienthal, Pilcher, Maxim, and Chanute, but will be inclined to believe that long before the year A.D. 2000 a successful aeroplane will have soared and come home safe and sound. Directly that is accomplished the new invention will be most assuredly applied to war."

When writing this, Mr. Wells had obviously never heard of the Wright Brothers' and the other important experiments which have been made during the last year. In fact, the first part of the prophecy, as we say, has already been fulfilled. It may therefore be of interest to readers of our aeronautical column to be reminded of the picture of the first operations in a future war, to which Mr. Wells has committed himself.

> "The fight between flying-machine and flying-machine, as we are trying to picture it, will be a fight of hawks, complicated by bullets and little shells. They will rush up and up to get the pitch of one another, until the aeronauts sob and sicken in the rarified air, and the blood comes to eyes and nails. The marksmen below will strain at last, eyes under hands, to see the circling battle that dwindles in the zenith. Then, perhaps, a wild adventurous dropping of one close beneath the other, an attempt to stoop, the sudden splutter of guns, a tilting up or down, a disengagement. What will have happened? One combatant, perhaps, will heel lamely earthward, dropping, dropping, with half its bladders burst or shot away, the other circles down in pursuit. . . 'What are they doing?' Our marksmen will snatch at their field-glasses, tremulously anxious. 'Is that a white flag or no?' . . 'If they drop now we have 'em.'"

Of course the reality may be quite different, but it is strikingly like Tennyson's similar vision about "The airy navies of the future grappling in the central blue," and prophecies by a prophet who has been successful even in a single prophecy, stand on a different level from most other utterances of the kind.



We are now able to reproduce, above, a photograph of the 40-inch Aeroplane Model promised by Mr. A. V. Roe in his letter to us, published on January 27th last. It is, as will be noticed, constructed on the lines adopted and developed so successfully by the Wright Brothers, and is fitted with its horizontal and vertical rudders. The extreme length of the aeroplane surfaces is 40 inches, their width is 6 inches, and they are 6 inches apart. Some interesting experiments having already been made by Mr. Roe with this model, he is now building a similar model of considerably larger size, after which he hopes to be able to make arrangements for building a practical motor-driven machine.

The Polar Airship.

The construction of the airship which is being built by M. Godard for Mr. Walter Wellman, the American explorer, and with which he intends to attempt to reach the North Pole next summer, is proceeding rapidly, and there is every reason to suppose that it will be ready at the time agreed upon. This machine, of which we hope to give some further details next week, is to be fitted with a 15-h.p. motor, and is calculated to attain an average speed of about 18 miles an hour.

Experiments at Aldershot.

Experiments with man-lifting kites are being carried out under the supervision of the military authorities on Laffan's Plain at Aldershot. The authorities are said to be very well satisfied with the results obtained, and Mr. Cody, with whose patent kites the experiments have been made and who has conducted them himself, on one occasion succeeded in rising as much as 26,000 feet into the air.

American Aero Club's Exhibition.

Of much interest to those interested in aeronautics was the subsidiary exhibit organised by the newly-formed Aero Club of America, which was held in connection with the Sixth Annual Automobile Show at the 69th Regiment's Armoury. Here were to be seen all sorts of machines, some of which, like Langley's, had actually flown by themselves, and, like one of the Lilienthal machines, had sustained an experimenter in the air in actual gliding flight. The principal exhibit was, in fact, the Langley aeroplane, which executed the longest free flight on the Potomac River ever accomplished by any machine of the heavier-than-air type without an aeronaut on board. There was also Professor Bell's tetrahedral kite, which is a wonderful multi-cellular arrangement looking not altogether unlike an elongated and greatly magnified chunk of honeycomb with the cells open and the honey taken out. It is provided, however, with front and rear tails similarly constructed, and is said to possess such stability that when launched from a balloon in mid-air it descends in a series of curves, sometimes going round in a complete circle like a soaring bird. Further exhibits of interest were the Herring dome kite, which is much like an enormous hat with a tail to it. One of the Lilienthal machines with which Lilienthal executed certain glides (though the longest and most frequent were accomplished with his multi-cellular machine) was shown, as well as the motor and part of the hull of Santos Dumont's No. 9. Models also of machines not differing noticeably from the accounts of the Wrights' motor-propelled machine were, in addition, exhibited.

The Vuina Aeroplane.

Experiments with the flying machine of M. Vuina, to which we referred last week, are still being carried out at Montesson. The arrangement, which consists of a pair of enormous wings and a motor-driven propeller, runs on a light quadricycle frame, which the propeller has proved itself able to drive at a considerable speed, and even uphill. The apparatus, however, has not yet risen in the air.

* * * *

Motor Samaritans.

Owing to the active co-operation with the police of the Automobile Association scouts, in many districts the trappists have ceased from troubling, and thus enable the bicycle scouts to be of further use to motorists by rendering them assistance in breakdowns. Last Sunday we heard of several such incidents on the Brighton road alone. Scout A.A. 5 was very practical in helping a stranded motorist over his ignition troubles, and A.A. 4 without any demur rode some miles to the Old Ship, Brighton, and secured help for an owner whose car had been rendered *hors de combat* by the roadside. Little acts of this sort refute the statements which have at times been made to the effect that the A.A. scouts, by their action, only assist scorchers in their malpractices.

Automobilism at the Antipodes.

Evidence of the great interest awakened in Australia by the Melbourne-Sydney Reliability Trials, which we described very fully at the time they were held, is provided by the fact that our contemporary, the *Scientific Australian*, devotes practically the whole of its Christmas number to automobile topics.

PUBLIC MOTOR VEHICLE REGULATIONS.

REVISED rules have now been issued by the Commissioner of Police as to conditions for proprietors obtaining a certificate of fitness for motor omnibuses for the Metropolis. On December 9th THE AUTOMOTOR JOURNAL published the suggested regulations which have since been revised after consultation with the representatives of the industry.

A recommendation by the Commissioner is that proprietors before entering into contracts for new types of motor omnibuses would do well to send the drawings to New Scotland Yard for approval as to type.

It is also specially added in a covering clause that the police conditions may have been complied with, yet, if there be anything in the construction, form, or general appearance which, in the opinion of the Commissioner, renders the carriage unfit for public use, it will not be licensed.

The following are the revised conditions which specially apply to mechanical vehicles. There are in addition the usual provisions in regard to space for passengers, display of fares, proprietors' names to be painted, lighting, &c.: —

Carriages must be submitted for inspection in a thoroughly good condition, and no carriage will be certified fit for public use unless it is newly painted and varnished. The following conditions must also be strictly complied with :—

1.—Stage carriages propelled by mechanical means, and subject to the Light Locomotives Act (59 and 60 Vict., cap. 36), and Motor Car Act (3 Edwd. VII., cap. 36), must comply with the requirements of those Acts and of the Orders of the Local Government Board made in pursuance thereof.

2.—Each new type of motor car, intended for licensing, must be presented at New Scotland Yard for inspection. The proprietor must, at the same time, produce the certificate of registration, and also one from the maker stating the machinery to be safe and in every way fit for use in a public carriage.

If, on inspection, the car is approved such approval may extend to all cars of that description, and cars of that type need not be again presented at New Scotland Yard; but may be taken to the usual passing station, provided a certificate from the maker is submitted with each car for licensing, stating that it is in every respect similar to the type already approved.

A certificate from the proprietor, stating there has been no alteration in the design of the machinery since the previous inspection and date covered by the maker's certificate, must be presented with each car submitted for renewal of licence.

Should an alteration be made, the same course may be required as for a first inspection.

Should it be deemed necessary, an expert will be employed to advise on the subject. The fee for the expert examination to be deposited by the proprietor with the Commissioner, which fee will be returned if the car is passed without alteration being required.

3.—The following measurements and requirements for an omnibus with top deck seats must be adhered to, and the number of passengers to be provided for on such vehicles must in no case exceed sixteen inside and eighteen outside :—

Chassis.

Length.—Not to exceed 20 ft.; but if the platform is carried on the frame the total length may be 23 ft.

Clearance.—The front axle and all the underworks of the car inside the knuckles of the steering joints (provided they are placed as near as possible to the wheels), as far back at least as the rear axle, must clear the ground at least 10 in. when the car is fully loaded, allowing half-an-inch in addition for new tyres to provide for wear.

Wheel Base.—Should not exceed 14 ft. 6 in., and it should in all cases be so proportioned that skidding or other improper movements shall be as far as possible avoided.

(NOTE.—The Commissioner reserves the right, even after a car has been passed, if it is found to be apt to skid unduly, to issue a notice on the proprietor not to use, and may refuse to license again until the defects have been remedied.)

Springs.—The springs must be properly hung, of sufficient strength and flexibility, to meet all purposes which may be required of them. Those springs carrying the load must be attached to, or bear upon the back axle, as near to the wheels as possible, the distance between the outsides of the rear springs, shall not be less than 45 in. The front springs must be as wide apart as possible, but not less than 38 in. from outside to outside. Where a cross spring is used, it must be so applied that it shall not cause or increase side sway.

Wheel Track.—Centre of must not be less than 5 ft. 6 in.

Body.

Height.—Inside, minimum 5 ft. 10 in., maximum 6 ft. Outside, from ground to spring of roof, 9 ft. Outside, from ground to centre of roof, 9 ft. 3 in.

Camber.—The camber should not be more than 3 in., but may, if the proprietor so desires, be made up to but not exceeding 5 in., provided the outside of roof is so constructed as to give an equivalent in all respects to a 3-in. camber, and the height from the ground is not in any way increased.

Guard rails.—The side guard rails must be 3 ft. from roof and 18 in. above the seats. The front and back guard rails must be 3 ft. 3 in.

Width.—Inside between seat backs not to be less than 56 in.
,, From off hind roof seat to back rail, minimum 26 in.

Steps.—Where more than one is used the staircase handrail must reach to the centre step, and be properly and rigidly fixed.

Length of Platform.—Not less than 36 in. nor more than 42 in.

The total overall length of the chassis and body must in no case exceed 23 ft., nor the extreme length be greater than 7 ft. 2 in.

Note.—Omnibuses which carry a less number of passengers than thirty to be made in proportion to the foregoing measurements as to length; but the number of passengers carried upon the outside must not be in greater proportion than seven to six inside.

4.—No canopy or other similar superstructure will be permitted on the roof of omnibuses constructed to carry passengers on the top deck.

5.—Each carriage must be fitted with at least two independent brakes of sufficient strength that either of them is capable of stopping and holding the carriage under all conditions.

NOTE.—The maintenance of the brakes in perfect order is of the utmost importance, and this will at all times be insisted upon. They will at any time be subject to inspection.

6.—Each car must be capable of being readily steered and able to turn a corner without unduly interfering with other traffic.

7.—The steering arms, &c., to be of sufficient strength, and as far as possible protected from damage by collision.

8.—The machinery should be so constructed that no undue noise or vibration is caused, and the maintenance of the carriage in this condition will be strictly enforced.

9.—Effective means must be adopted for the radiation of heat, and cooling of the parts subject to heat.

10.—All wires carrying electric current to be sufficiently insulated and placed so as to be free from danger.

11.—Tanks for petrol or other liquid fuel must be made of suitable material, properly constructed, and of sufficient strength. They should be so placed that any overflow shall not accumulate on woodwork, or where it can be readily ignited. The filling nozzle or inlet for the petrol or other liquid fuel should, where possible, be brought to the outside of the body.

12.—Suitable appliances for extinguishing fire should be carried in such a position as to be readily available for use.

13.—Driving chains and sprockets to be protected by a suitable guard.

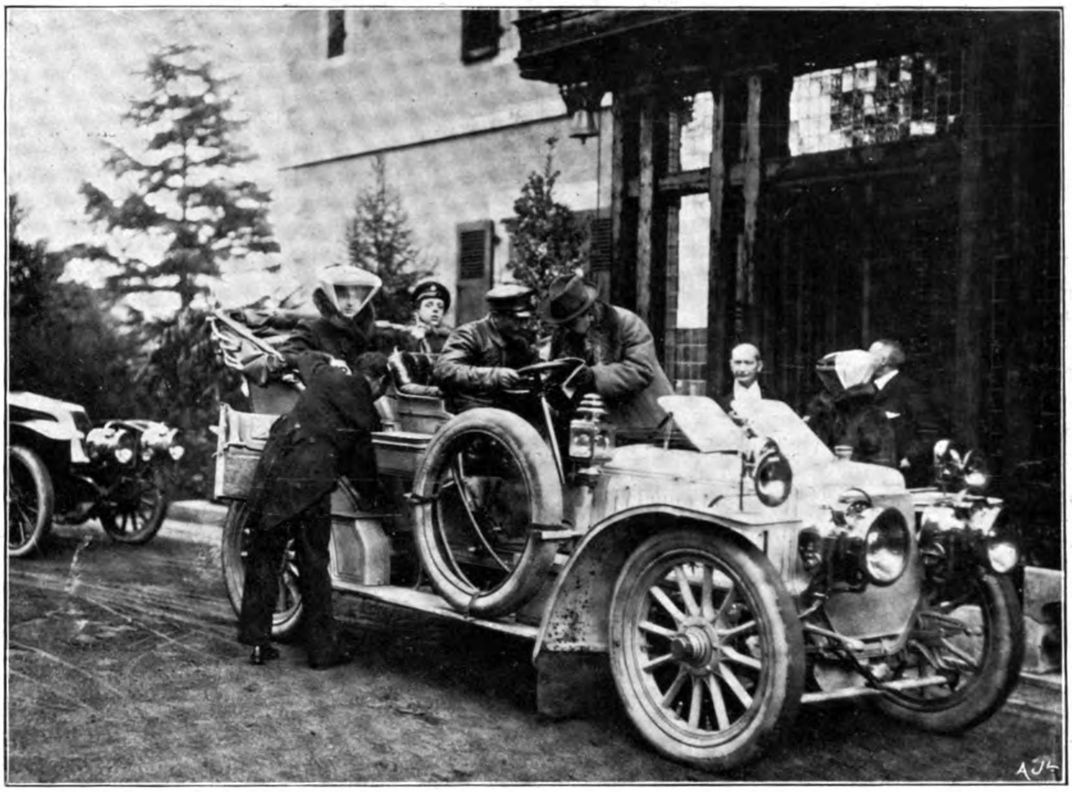
14.—Head lights of great brilliancy will not be permitted.

No celluloid or xylonite fittings to be placed inside or outside, but this does not apply to the inside of accumulators.

⁂

The Car of Cupid.

KING ALFONSO's motor car continues to render him such excellent service in his journeyings to and from Biarritz that the peasantry of the district have dubbed the Royal automobile "Cupid's car," and some of the natives have even been moved to write poems on the inspiring subject. We are able this week to give photographs of the King, Princess Ena, and the Queen Mother *en automobile.*



The King of Spain and Princess Ena of Battenberg just off for one of their daily motor drives from Biarritz.

Motor-Driven Fire Engines for Straits Settlements.

FOR use in hot climates, Messrs. Merryweather consider that the steam-propelled fire engine, such as their "Fire King" type, of which we have given full particulars in this Journal, is preferable to the petrol engine, of which they are also making large numbers. It is interesting to note that the Selangore Fire Brigade has had a steam fire engine in regular use for over three years, and Messrs. Merryweather have now supplied a similar machine for Penang. Ordinary petroleum is burnt in the furnaces under quick-steaming water-tube boilers, and a small gas or oil heater is temporarily used in the station, so that the engine can be turned out in under a minute in the event of a "call." The facilities for starting from cold, possessed by the petrol engine, are, of course, obvious, and in many cases this alone would act as a heavy balance in their favour. In tropical climates, however, it is easy to understand that the free use of petrol in a fire station is not desirable, but the Singapore and Penang brigades are to be congratulated on having self-propelled engines, all the same.

Enterprise by the M.F.B.

LONDON is also keeping abreast of the times, and the Metropolitan Fire Brigade have just acquired another "Motor Fire King," the trials of which were successfully carried out at the Southwark headquarters, under the superintendence of Mr. Gordon. As a test the machine was taken for a 70 mile run; it is geared to 30 miles per hour and can climb almost any hill at about 10 miles per hour, its pumping capacity is 500 gallons per minute.

More Cars for Bishops.

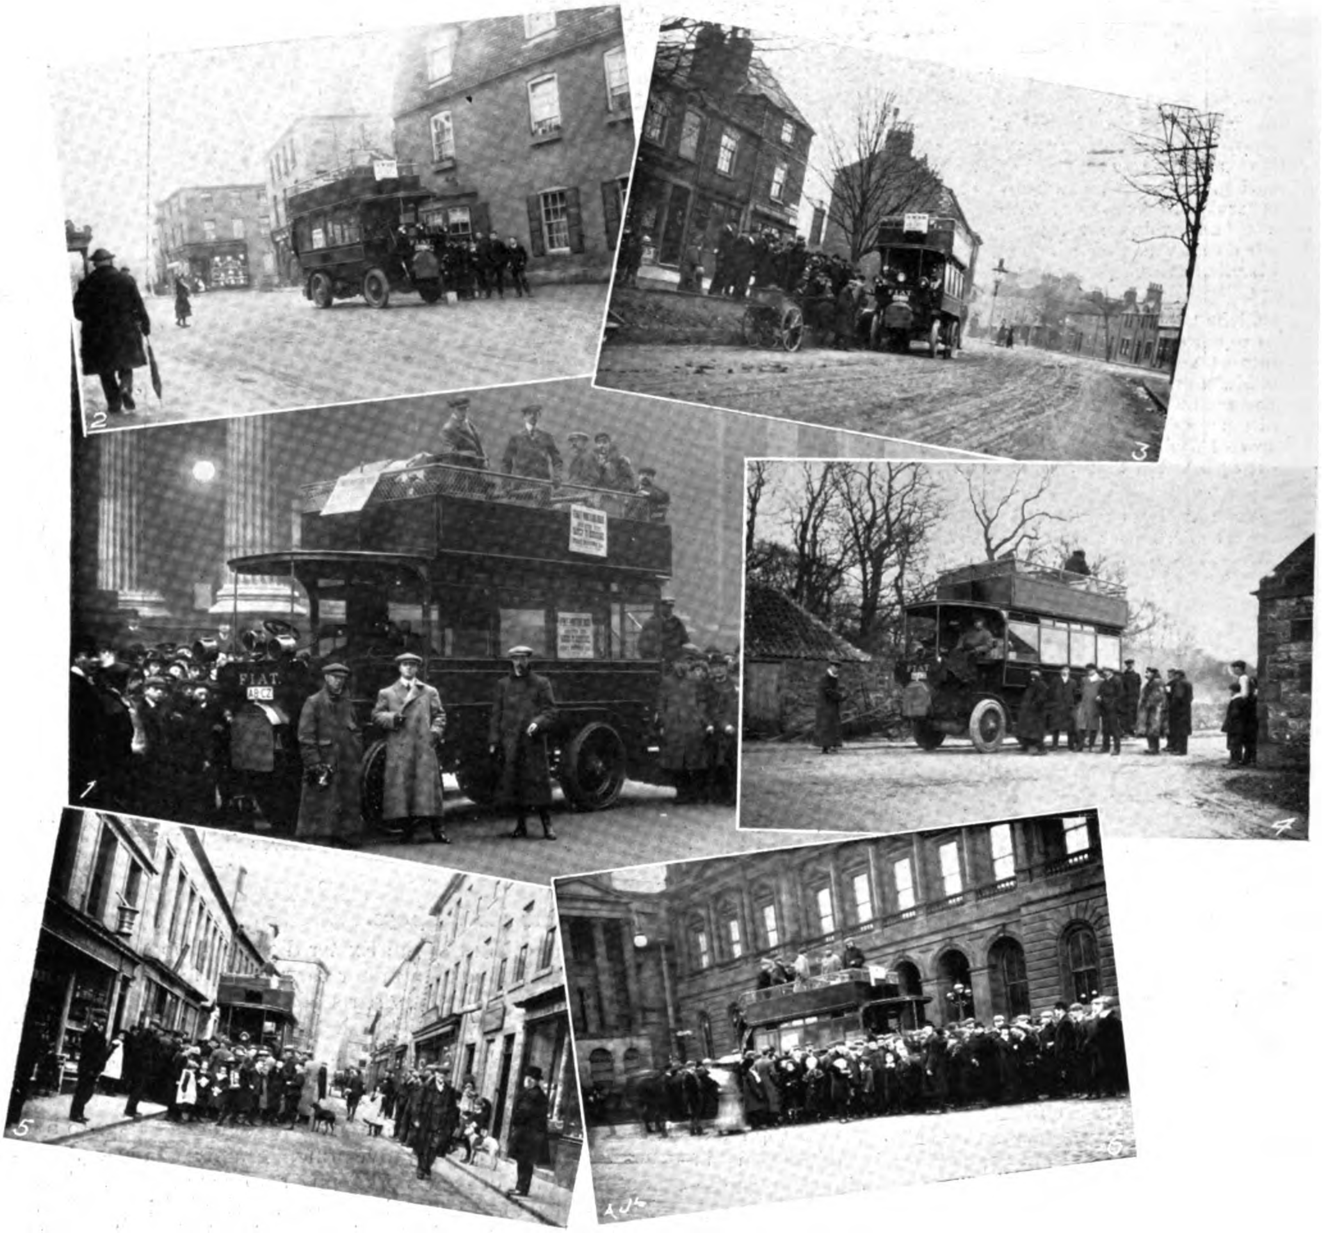
CHURCHMEN in the Exeter diocese propose presenting the Bishop with a motor car to enable him to reach more readily the remote parts of his see. In the diocese there are nearly 500 parishes, many of which are far distant from a railway station.

Co-operative Garages.

IN America, the proposal for arranging a garage to be organised upon co-operative principles amongst the leading automobilists of New York, appears to be maturing. It is to be called the "Club Garage of America," with premises in 62nd Street and Broadway. The A.C. of America have deemed it advisable, coincident with the "Club Garage" announcements, to issue a notice calling attention to the fact that there is no connection between the new garage and the A.C.A. Garage, which is now being built independently for the Club.

Mr. Charles Jarrott—hys Booke.

MR. JARROTT has arranged to write a book dealing, amongst other things, with automobilism in the early days, his experiences in connection with earlier types of cars and machines, and also his experiences on the road in the big Continental races in which he has taken part. The book will contain a chapter on motor cycling and motor cycle track racing, and an account of the disastrous Paris-Madrid race, in which Mr. Jarrott played so prominent a part. The book, which will be fully illustrated, will be published by the firm of E. Grant Richards, 7, Carlton Street, S.W., at half-a-guinea. Such a store of motoring experiences as Mr. Jarrott's should make the work cheap at double the price.



Photos by Wakefield, Brentford.

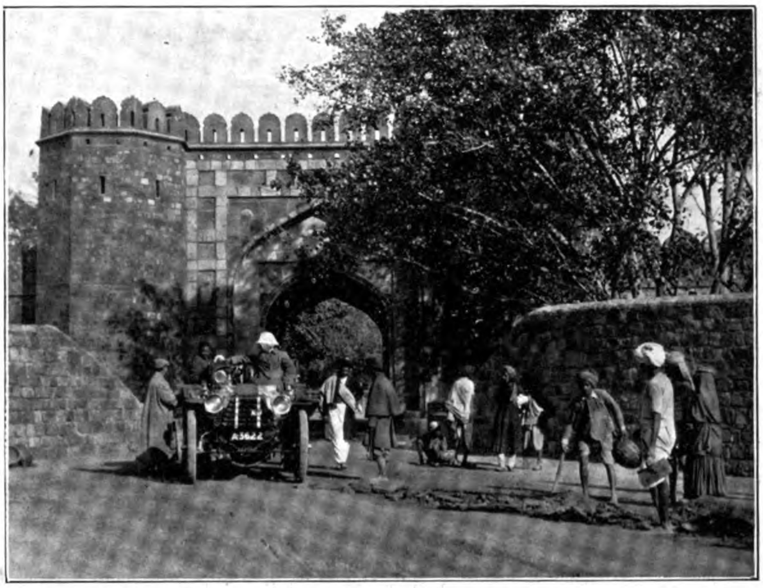
FROM LONDON TO EDINBURGH BY MOTOR OMNIBUS.—The run of the Fiat 'Bus on January 26th constitutes an unique record for such a performance. The above series of photographs secured by Mr. Wakefield, who accompanied the 'bus throughout, at various points en route, form an interesting souvenir of the journey. Our photographs, respectively, are taken at—1, the General Post Office, London (the start); 2, Biggleswade; 3, Grantham; 4, Morpeth; 5, Berwick; and 6, the General Post Office, Edinburgh (the finish).

Motor 'Bus Titles.

Some time ago we drew attention to the manner in which the companies running motor 'buses are reviving the old custom common in London in the early days of the horse 'bus and in the times of stage coaches, of employing special catch names for different services. Already we have had the "Vanguard," the "Arrow," the "Dart," and the "Pioneer"; now the "Victoria," the "General," and the "Union Jack" have been added, special interest attaching to the latter brand by reason of the fact that the first Clarkson steam 'buses in the Metropolis are serving under that banner.

Motoring in the Himalayas.

Describing a trip in the Himalayas, a correspondent in the *Pioneer* states that he believes his experience to have been the first motor climb in these famous mountains. The run was made in an 8-h.p. De Dion-Bouton car from the Dhukrani Estate, Western Dun, to Chakrata and back again, a total distance of 72 miles, which were covered in 7 hours, including all halts. Dhukrani is 1,300 ft. above sea level, and Chakrata close upon 7,000 ft., and the road for the last 15 miles of the upward journey is described as appearing "rather like a goat track, winding so steeply round impossible looking corners."



Reminders of Mr. C. J. Glidden's long touring trip are reaching us from time to time as postal opportunities serve. Our photograph shows Mr. and Mrs. Glidden and their Napier, A.3622, at the Cashmere Gate, Delhi. He has driven his car 5,000 miles in India since landing at Bombay—a longer distance than any other touring automobilist has hitherto accomplished in the Indian Empire.

Municipal Progress.

THE Chelsea Borough Council have decided to start a service of ten motor dust carts in the Borough at a cost of about £10,000.

A State Car.

IN one respect, at any rate, the colony of Australia is ahead of the mother country. The State of Victoria has adopted a state motor car, which is placed at the disposal of the Premier. This has enabled him to inspect many hundreds of miles of territory. He is so pleased with the vehicle that, on one occasion, he covered some ten miles in 15 minutes, there being, presumably, no law in the colony to prevent his doing so.

New Yorkshire 'Bus Services.

GASSINGTON, Keighley, Bolton, Skipton, Ilkley, and Addingham are, we understand, shortly to be served by motor omnibus services from Silsden as a centre. Vehicles capable of seating 36 passengers will be supplied to a Yorkshire company by the Scottish Motor Engineering Company, and will be British-built throughout. Slow speed (max. r.p.m. = 700) 4-cylinder engines capable of developing about 36 h.p. will be fitted to these cars, and the control mechanism will be simplified as much as possible. Sliding-spur-wheel change-speed gearing will not be used, for a type in which the gear-wheels are always in mesh has been designed instead. Side-chains will be adopted as the final transmission to the road-wheels, and the normal gearing will provide three alternative speeds of 3, 6, or 12 miles per hour respectively.

Importers Combine.

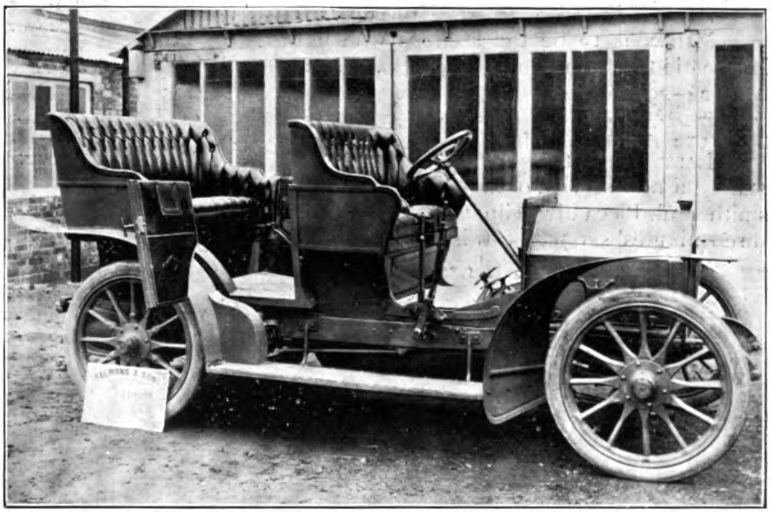
MOTOR car importers have formed an association, under the title of The Importers' Protection Association, for the guarding of their combined interests.

The Motor in the Malay States.

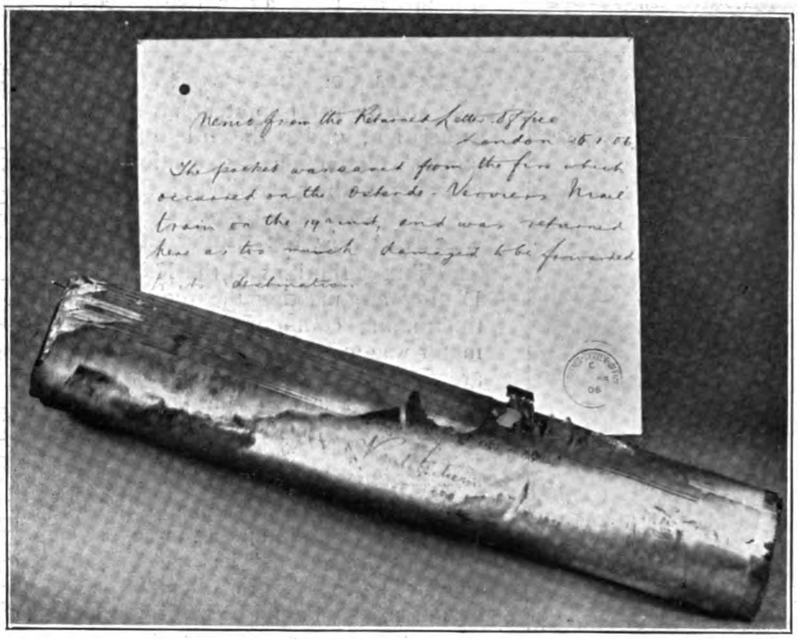
THE authorities of the Kuala Lumper District are meeting the requirements of the mining community by purchasing a motor wagon for transporting metal. They are following this departure up by completing the roads to Ginting Simpah and Petaling.

An Ingenious Camera Stand.

A NOVEL form of camera stand, which is being put on the market under the name of the "Swingcam," has been submitted for our inspection. It is ingenious in construction, and should prove of considerable value to photographers, whether amateur or professional, especially those engaged in engineering work. It is capable of every possible movement, and can be placed so as to direct the camera in every conceivable position. The normal height is 5 ft. 9 ins., but with extension bars, which can be supplied with it, the camera can be placed as high as 7 ft. 3 ins., enabling the most varied work possible to be carried out.



For some time a very realistic series of cinematograph pictures have been a feature at the Palace Theatre, depicting the building of a motor car in every detail, from the commencement to the finish, in (on the screen) the record time of about four minutes. Such celerity can hardly be expected in actual practice, but a smart piece of work in carriage body-building is related to us in connection with the above photograph by Messrs. Charles Jarrott and Letts. They write as follows:—"At 6 o'clock on Saturday morning last we despatched to Messrs. Salmons and Sons, coachbuilders, of Newport Pagnell, a 12-15-h.p. De Dietrich chassis, to which we required a body fitted, the car complete to be sent to the Edinburgh Exhibition. The chassis left London at 6 o'clock on Saturday morning, and arrived at Messrs. Salmons and Sons at 10.15, and shortly after 10 o'clock the same night, that is, just 12 hours later, the body was mounted and fitted with wings, steps and everything complete ready for the road, and the car complete was sent up to Edinburgh by the next train."



Recd from the Returned Letter Office
London 26.1.06.
The packet was saved from the fire which occurred on the Ostende-Verviers Mail train on the 19th inst, and was returned here as too much damaged to be forwarded to its destination.

A relic of the Ostende-Verviers Mail Train Fire. The Post Office is often unjustly blamed for delay and carelessness in handling letters and parcels. The other side of the picture is seldom presented. An instance of the latter is the return to the Automotor office of the copy of the Journal which we reproduce in the above photograph with its covering official note from the G.P.O. It is another case of the "yellow cover" identification. Practically no printing or address could be deciphered, but the "yellow cover" gave the clue and with commendable promptness the "packet" has been returned to us for our information.

Third International Congress.

MILAN is to be the scene of the next and Third International Automobile Congress. The date fixed is May 24–29th.

A "Rapid" Service.

LAST week the Rapid Road Transit Company started a new service of motor 'buses between Hammersmith and Piccadilly Circus. They intend making a three-minutes' service on this road.

Motor Launches on the Thames.

A JOINT deputation of the Society of Motor Manufacturers and Traders, the Marine Motor Association, the Motor Boat Club, and the Motor Yacht Club, will shortly wait on the President of the Board of Trade for the purpose of putting before the Board objections to the proposed bye-laws and regulations for motor launches on the Thames, drafted by the Thames Conservators. Full particulars of the bye-laws in question were published in the pages of this Journal, on September 16th last. It will be remembered that, although for the most part of an irreproachable character, some of them appear to be unnecessarily stringent.

Edinburgh 'Bus Service.

THE Scottish Traction Company, which was formed last autumn for establishing motor 'bus services in Edinburgh and other districts, has just received its first motor 'bus from the Maudslay Motor Company.

COMMERCIAL POINTS.

The Panhard and Levassor Travelling Workshop.

THIS popular van is about to start out on another tour. During the next few weeks it will visit the following districts:—Hants, Wilts, Dorset, South Devonshire, Cornwall, North Devonshire, Somerset, Gloucester, Worcester, Hereford, Montgomery, Shropshire, and Warwick. Actual date of the visit may be obtained by dropping a card to 14, Regent Street, London, S.W.

THE Continental Tyre Company advise us that they have now opened their new motor tyre repair works at Hythe Road, Willesden Junction, which they have fitted up with modern machinery and up-to-date equipment necessary for the prompt and efficient repair of motor tyres. They are in a position to execute repairs of all kinds to motor covers and inner tubes within a few days from receipt.

THE Coventry Chain Company. Ltd., advise us that they have a display of their chains for automobiles and commercial vehicles at the Automobile Exhibition in Berlin at Stand No. 102, and their Mr. Norman Hill and Herr Thater will be in attendance.

THE 200-h.p. Darracq, on which Demogeot, on the Ormonde Beach, Florida, covered 2 miles in 58⅘s., was fitted with Dunlop motor tyres.

MR. G. HUBERT WOODS, late manager to Messrs. Cockshoot and Co., Manchester, engineer, has taken up the management of the Simms Manufacturing Company, Ltd., for the engine, motor car, 'bus, van, lorry, and Simms-Bosch magneto departments.

MR. JACOMB-HOOD, the chief engineer of the South-Western Railway, has just purchased a 10-h.p. Rolls-Royce car.

IMMEDIATELY on his arrival at Edinburgh on his non-stop engine run from London, Mr. Charles Jarrott wired to the Continental Tyre Company as follows: "The Continental tyres on my Crossley car behaved splendidly, no trouble of any kind, distance covered, London-Edinburgh, in 20 hrs. 35 min. without stopping engine.—JARROTT."

Sirdar Rubber Co., Ltd. v. Wallington, Weston and Co.

THE appeal of the Sirdar Rubber Company, Ltd., in this action has been dismissed on the ground of the patent being inadequately described by the specification. But the Sirdar Company inform us that they are advised that there is sufficient description in the specification, therefore they are appealing to the House of Lords.

CLIMBING SALISBURY CRAGS, EDINBURGH.—At the summit of the Crags.

COMPANY DOINGS.

Car and General Insurance Corporation, Limited.

THE directors' report, and accounts of this insurance company just issued, show a very satisfactory condition of affairs. The gross premium income amounts to £71,959, and the net premium income to £64,475, as against a net premium income of £26,828 for the previous twelve months. During the year 1,624 new agents, as against 1,443 for last year, have been appointed, making a total of 3,067. Ten district managers or agency superintendents have been appointed to work from Brighton, Bristol, Croydon, Ealing, Hereford, North of London, Norwich, Nottingham, Sheffield, and West End of London, making a total of twenty branches. The whole of this agency and branch organisation has been obtained at a capital outlay of £7,821. The percentage of gross expenses (*i.e.*, before deducting any sum on account of branch or agency organisation) to net premium income has been reduced from 51·4 per cent., for 1904, to 40·4 per cent. for last year. The directors recommend, after writing off the whole of the preliminary expenses, amounting to £1,751 18*s.* 8*d.*, that the balance of £1,409 14*s.* 3*d.* should be carried forward.

Omnibus Company Reports and Motor 'Buses.

IN the directors' reports of the Associated Omnibus Company, Limited, and the London Road Car Company for 1905, issued last week, some matters of interest to the motor world are recorded. The report of the former states that the traffic receipts of the horse omnibuses show a falling off as against the previous year, and maize has been dearer, but the total receipts have been maintained by the addition of the motor omnibus returns and increase of private hire. Owing to the rapid increase of motor omnibuses in London, and in order to keep abreast with the times, the directors decided to augment the working capital of the company by creating £50,000 of 5 per cent. debenture stock. Of this sum, the Board issued in December £25,365, which it is considered will be sufficient for some little time. The Board has entered into contracts for the supply of a large number of motor chassis by Messrs. Milnes-Daimler, Limited, the De Dion Bouton-Company, Straker-Squire, and others, and have eight already at work. A commodious garage has been erected in close proximity to the company's principal routes, fitted with electric light and necessaries for the carrying on of the business. The directors deem it expedient under the circumstances paying only 6 per cent., and writing off a considerable sum from the horse and omnibus stock, thus extinguishing the item under the reserve accounts of horse renewals, £5,335.

The Road Car Company.

EQUALLY significant are the recommendations of the directors of this company, who report that, after allowing for the usual depreciation, they recommend a dividend for the half-year ended 31st December last at 5 per cent. per annum, setting aside £5,000 towards writing off horses, horse cars and harness put out of use through the introduction of motor traction, and the setting aside of £1,000 towards the depreciation and renewal of motors.

* * * *

The "Freak" Car fatal Accident.

AT the inquest held upon the body of William Edward Honnor, who received injuries which proved fatal at the works of the Clement Motor Company, Leicester Street, Leicester Square, the jury returned a verdict of accidental death, expressing the opinion that the Clement Company took all necessary care for the protection of their workmen.

Mr. Edward Henry Lancaster, managing director of the Clement Motor Company, said the car which was the cause of the accident was brought to him to be overhauled. It was a "freak" car—nothing more or less. As none of his men understood it, he sent it to a man at Wimbledon who did, and he delivered it to witness about three weeks ago, finished. It was sent to the second floor to be polished and, in moving it, the steering gear broke. It was then sent to the top floor to be repaired. Deceased was given the order to repair it, but how he started the engine witness could not say.

The Coroner, in summing up, said it was one of those cases which showed that it was a commonsense and prudent rule to lay down in motor works that under no circumstances must an engine be started. The car had been described as a "freak." Certainly it was very different from the ordinary type of motor car, and it could only be conjectured that deceased, curious about the working of the car, unfortunately started it.

LEGAL INTELLIGENCE.

"Motor Schools"—the Alleged Frauds.

AT Westminster Police Court, on Feb. 1st, before Mr. Curtis Bennett, Riski Madawar, 22, a Turkish subject, described as a motor-car dealer, of 47, Victoria Street, Westminster, and John Raymond Kerr, 21, clerk, of Warwick Gardens, West Kensington, fashionably-dressed young men, were again charged with conspiracy to defraud and with obtaining money by false and fraudulent pretences to teach pupils motor car driving.

Mr. Leycester was counsel for the prosecution, and Mr. Charles Mathews, barrister, appeared for the defence.

The vestibule of the court was filled with young men interested as prosecutors or witnesses.

Mr. Leycester said the prosecution was of an important character, the defendants having carried on a bogus business, known by the high-sounding title of "The Motor Drivers' Union." The case against the prisoners was that this concern existed only for the purpose of obtaining money from young men anxious to qualify as motor drivers. The offices were at 47, Victoria Street, S.W. Madawar was represented as the proprietor of the business, and Kerr as the secretary. By extensive advertising, from July last until last month, a very large number of young men had been defrauded of sums ranging from four to fifteen guineas. The advertisement stated that the "Motor Drivers' Union" gave instruction in driving, mechanism of motors, and repairs, that the cars included the latest 1905 types, and that many vacant berths were at the disposal of pupils. Applicants to the prisoners were furnished with pretentious-looking documents setting out that the business was "founded for the welfare of established and prospective chauffeurs," and persons were warned against many advertised schools. The garage was referred to as the best-equipped in London, and a Press notice—from a trade journal—was sent out accompanied by pictures supposed to represent the classes of young men receiving instruction. The notice throughout was written in a highly-eulogistic strain, the garage being referred to as in "the heart of the West-End." As a matter of fact, it had its existence in a disused stable at Coach and Horses Yard, Old Burlington Street, and particular care was taken that none of the pupils saw it until after they had parted with their money. The only instruction ever given with regard to mechanism was a lecture on a motorcycle engine. The farce was gone through of giving what were called driving lessons on the Thames Embankment, the pupils being taken for a brief ride and allowed for a minute or two to hold the steering-wheel, but not to touch the machinery.

Evidence was called in support of counsel's statement.

Mr. Davis, one of the pupils, stated that when he complained of the misrepresentation about the garage, &c., Madawar said if a pupil upset him he would show him something so terrible that he had never seen in England before. Prisoner subsequently told the witness never to let him see his face again. Witness retorted, "Only at the police court."

Mr. Charles Mathews said he had read through the informations and recognised it was a case which the Court would probably send for trial. Under the circumstances he did not propose cross-examining the witnesses at this Court, but it must be understood that the defendants reserved their defence, and that at the proper time it would be shown that there was a perfectly *bona-fide* school of instruction.

The case was further adjourned after other evidence.

* * * *

Rolls-Royce Extensions.

THE manufacture of Rolls-Royce cars will, in future, be carried on by a new Company called Rolls-Royce, Limited, the capital of which is £60,000. The principal shareholders are Royce, Limited (who are receiving only debentures and shares), and the Hon. C. S. Rolls, whose firm, C. S. Rolls and Co., are now absolutely devoting themselves to the sale of the Rolls-Royce cars. A considerable quantity of new machinery and additional machine tools have been ordered, by which the output of the factory is being greatly increased. It is understood that the new Company is only a stage in a scheme of considerable proportions.

* * * *

NEW COMPANIES REGISTERED.

Fylde Motor Service Company (Limited), Blackpool and Fleetwood Tramroad Office, Bispham, near Blackpool.—Capital, £20,000 in £1 shares. Object, to acquire the Fleetwood Motor Passenger Carrying Company, Limited. First directors, R. S. Boddington, G. Richardson, R. H. Prestwich, R. B. Barningham, J. Greenwood and J. Cameron.

NEW COMPANIES REGISTERED (*Continued*).

Aries (Limited).—Capital, £1,000 in £1 shares. Object, to carry on the business of manufacturers of and dealers in motors and cycles of all kinds, &c.

Bougie Pognon (Limited).—Capital, £5,000 in £1 shares. Object, to carry on the business of manufacturers of and dealers in motors, motor cars, &c. First directors, M. Hobson, C. Hobson, H. Hobson, and E. A. H. de Poorter (managing director).

Chassis and Coach Supply Company (Limited).—Capital, £5,000 in £1 shares.

Devonshire Motor and Cycle Company (Limited), 192, Brookhill, Sheffield.—Capital, £1,000 in £1 shares. Object, to acquire the business carried on at Sheffield by John T. Walker and Ada Walker. First directors, J. T. Walker and H. W. Webster.

General Motor Development Syndicate (Limited), 7ab, Lower Belgrave Street, S.W.—Capital, £5,000 in £1 shares. Object, to promote motor, cycle, and other companies. First directors, J. J. Mann and G. Oakey.

Headingley Motor and Engineering Company (Limited), 18, St. Michael's Lane, Headingley, Leeds.—Capital, £1,000 in £1 shares. First directors, J. J. Nicholson and J. S. Saville.

Hull City Garage (Limited), 7, North Street, Hull.—Capital, £10,000 in £5 shares. Object, to acquire from A. J. Atkinson, of Elloughton, Yorkshire, the undertaking of the City Garage carried on by him in North Street, Hull. First directors, A. K. Dibb, A. J. Atkinson, G. W. T. Wade, T. M. Newell, A. Reckitt, and E. S. Wade, J.P.

Ilford Accumulators (Limited), 13, Borough High Street, S.E.—Capital, £12,500 in 11,500 preference shares of £1 each, and 20,000 founders' shares of 1*s*. each.

Kennard Motor Company (Limited), 18, City Road, Cardiff.—Capital, £3,000 in £1 shares. Object, to adopt an agreement with W. E. Kennard for the acquisition of the business carried on by him at 18, City Road, Cardiff, of dealers in motor and other cars, &c.

Mercial Tyre Company (Limited).—Capital, £2,000 in £1 shares. Object, to adopt an agreement with J. C. Akerman and J. T. Akerman, for the acquisition of patents for an invention relating to improvements in the manufacture of motor tyres.

Motors (Blackpool) (Limited).—Capital, £3,000 in £1 shares. Object, to carry on the business of motor garage proprietors, dealers in motor cars, &c. First directors, T. Bannister, H. Merrall, J. R. Huddlestone, and R. Woodhead.

Nesbitt and Cunliffe (Limited).—Capital, £5,000 in £1 shares. Object, to acquire and carry on the business of motor, electrical, and general engineers, carried on by E. A. Nesbitt and E. H. Cunliffe, at Myron Place, Belmont Hill, Lewisham, as Nesbitt and Cunliffe.

Pherola Spring Wheel Company (Limited).—Capital, £15,000 in £1 shares (5,000 "A" and 10,000 "B"). First directors, P. J. Neate (chairman), B. R. Wills, K. Ahlquist, R. M. Neate, and A. Wills.

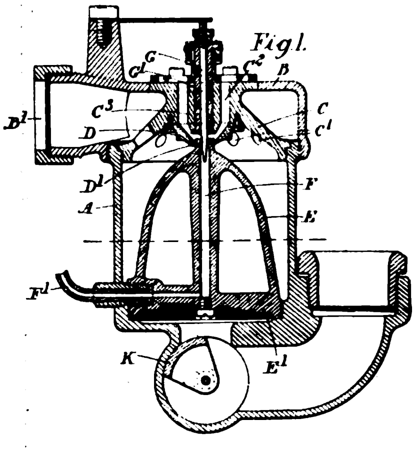
Weigel Motors (Limited).—Capital, £7,500 in £1 shares. Object, to carry on the business of manufacturers of and dealers in motor and horse-drawn carriages, airships, balloons, &c.

* * *

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

14278. 11th July, 1905. Improvements in or relating to Carburettors for Internal Combustion Engines. Charles Robinson, 60, Park Road, Bromley, and George Mole, the Cottage, South Hill House, Bromley. This invention has for its object to provide a carburettor having a non-suction fuel supply and means by which this fuel supply can be regulated either automatically or by hand for the purpose of controlling the engine. The fuel is fed to the air supply by gravity, and can be controlled so that a constant supply is fed to the mixing-chamber, such supply being in no way affected by the speed of the engine. There are four figures. Fig. 1 is a central vertical section through the carburettor. A casing, A, constitutes the mixing-chamber, and has screwed on to it a cap, B, which closes the upper end of the chamber, and has an air inlet, B¹. The upper end of the casing, A, has an internal thread which receives a conical annulus, C, having perforations, C¹. The upper end of this annulus extends through the cap, B, so that air entering the chamber, A, from the inlet, B¹, has to pass through the perforations, C¹; the central aperture, C², of the annulus is open to the atmosphere. Secured to the underside of the annulus, C is a circular baffle, D, having a central orifice, D¹. Within the mixing-chamber, A, is a conical body, E, secured to the lower end of the mixing-chamber and extending upwardly therefrom, and through the centre of this body is carried a petrol nozzle, F, which extends through the orifice, D¹, in the baffle, D, so that it is in free communication with the atmosphere by way of the aperture, C². The nozzle is fed by a conduit, F¹, communicating with a source of supply situated at a higher level than the nozzle, so that gravity will cause the petrol to flow from the nozzle on to the exterior of the vaporising cone or body, E. Above the nozzle is a valve having a tapered spindle, G. which enters the mouth of the nozzle. The spindle is carried free in a sleeve, G¹, which slides freely in a central boss, C³, with which the annulus, C, is provided. This boss is situated centrally in the aperture, C², and connected to the annulus by suitable webs. The throttle, K, is first opened by turning the rocking shaft, which may be effected by any suitable mechanism operatively connected with the arm. This movement of the rocking shaft raises the sleeve, G¹, so that the spindle, G, is lifted partially from the valve nozzle and petrol escapes. This gravitates down the exterior of the nozzle and over the exterior face of the cone, E The engine is now started, and sucks air through the inlet, B¹, into the chamber, A. The air enters the chamber through the orifices, C¹, in the annulus, C, which serves to disperse the incoming air, so that it enters the chamber on all sides instead of on that side only which is nearest to the inlet. The air passes through the chamber, A, to the throttle valve, K, and in doing so becomes carburetted by its contact with the petrol exposed on the surface of the cone, E. The cone, E, is carried by four webs, E¹, which are screw-threaded to engage a corresponding screw-thread on the interior of the chamber, A, but an annular space is left between the cone and the wa of the chamber.—January 17th, 1906.



18832. 18th September, 1905. Improvements in or relating to Sparking Plugs for Internal Combustion Engines. Alfred J. Boult. A communication from Léon Macquaire, 21, Rue de Malte, Paris. This new plug is arranged in such manner that by means of a hollow electrode and a blow-off valve or cock arranged to control the passage through this electrode it is possible to clean it in a perfect manner at any moment, and without taking it to pieces, so that it and at the same time the cylinder of the engine may be readily cleaned, and whereby compression valves or cocks as at present used can be done away with. There are two figures. Fig. 1 is an elevation of the plug partly in section. The main body, 1, of the plug terminates at the bottom in a cap, 2, either made in one piece with it or secured to it, cut out in the centre in the shape of a cross or star, so that a variable number of points can be obtained for producing sparks. In the body, 1, is placed the porcelain part, 3, perforated for the passage of the hollow electrode, 4, a recess being provided in its upper portion for receiving the nipple, 5, terminating the bottom of the second porcelain part, 6. An asbestos joint is arranged between the body, 1, and the porcelain part, 3. The second porcelain part, 6, is arranged direct on the part, 3, the shoulder, 7, of the electrode, 4, engaging with the recess in the nipple, 5. A nut, 8, surrounding the porcelain part is screwed into the interior of the main body, 1, pressing by means of the shoulder at the bottom part of the porcelain, 6, and of the bottom reduced portion of the main body, 1, the two porcelain parts one against the other. An asbestos joint could also be placed between the base of the nut and the shoulder of the porcelain, 6. The tube, 4, or central electrode terminates at the top in a screw-threaded portion intended to receive a sleeve or nut, 9, which ensures its stability during erection owing to the pressure which it exercises on the shoulder, 7, arranged in the recess of the nipple, 5, of the porcelain part, 6. Its bottom portion is simply split, say, into four in the example illustrated, in order to obtain four points corresponding to the four branches of the cross-shaped cut out in the cap, 2. The production of sparks will, therefore, take place between the points formed by the lines of slots of the tube and the points of the star or cross, this multiplication of the points of sparking ensures good working, and this division of the end of the tube enables, when the valve is opened and the gases escape, the cleaning of that part of the plug to be effected in a thorough manner inside and outside. Round the nut, 9, and the upper portion of the porcelain part, 6, which is slightly reduced at that point, are arranged two fibre washers, 10, which prevent air from coming in contact with the porcelain, and give protection against shocks, and ensure perfectly tight joint of the whole. They are pressed against the upper non-reduced portion of the porcelain part, 6, by screwing down the valve, 11, on the nut, 9. The plug of the valve or cock, 11, is perforated, and terminates in a handle, 12, made of fibre or some other insulating material.—January 17th, 1906.

PASSING EVENTS.

"The Automotor Journal" Buyer's Guide.

The motor car industry is in such a flourishing and expanding condition, and the manufacture of automobiles has become so important and profitable a business, that the types and numbers of useful and serviceable cars, which but a few years ago could be numbered on the fingers, now run into a good many hundreds. The perplexity of the intending purchaser who, having been converted to the advantages and charms of the new locomotion, has decided on becoming the owner of a car, have accordingly increased by leaps and bounds also, and it has become a very difficult undertaking for him to form an idea, in the first place, of the sort of vehicle he wishes to purchase, and in the second place, of how far, when he has decided that point, anything corresponding to it at present on the market comes within the limits of expenditure which he is willing and able to incur. Anything that renders it easier for him to settle what he really requires and come rapidly to a decision, should prove a comfort to him. With a view to simplyfying matters, therefore, and enabling prospective customers to see at a glance the characteristics of the principal cars on the market, what they can accomplish, the price that is asked for them, and the main details of their consruction, *i.e.*, the type of engine, gear, number of speeds with which they are fitted, kind of ignition employed, the type of clutch adopted, and all the other features which may be of importance in a car, we have arranged, collated, and classified in tabular form all the necessary information of this character. This "buyers' guide" is arranged in very much the same way as that which we published at the time of the last Olympia Show, but it contains practically every known make of car which is at present on the English market, whereas our earlier tables referred only to cars on view at the Show. As before, those items, which every intending purchaser must primarily take into consideration, are grouped together under a separate sub-heading in the first few columns, and the following columns give further particulars, mainly of an engineering kind, which most purchasers wish to know before finally deciding on any particular car. But in this new "guide" we have been able to go much further than before, and on the extreme right of each page will be found the country of origin of each car, *i.e.*, whether it is British-made, or manufactured in some other country—information which we are, we believe, the first ever to have collected and published—and references to the volume and pages of The Automotor Journal, in which full descriptions of each of the cars have already appeared.

◆ ◆ ◆

To Facilitate Selection.

These tables therefore will provide the motoring public with a birdseye view of the whole automobile industry. The moment he has formed even a hazy general conception of the kind of car that he requires, even if he has decided on nothing further than the number of people it is to carry, the speed at which it is to go, and what it is to cost, he can look down the table and find a certain number of cars that more or less conform to these requirements. Then when he has selected, say, a dozen or more cars that in these respects may possibly suit him, he will, if he has any special preference for any particular type of engine, gear, drive, or other characteristic, be able to reduce his list still further, and if he is still desirous of information to assist him in forming his final selection, he can, in the majority of cases, obtain it by referring to the back numbers of The Automotor Journal, in which we have described the car or cars which form, say, his final selection.

It is not only, however, to the prospective purchaser that our "Buyer's Guide" is calculated to prove of assistance, for everyone interested in the statistics of the motor car industry will have a great portion of the information they are likely to require tabulated for them and ready in its most concentrated form.

It is our hope that the tables may be found thoroughly useful, in fact, to everybody connected with the automobile movement, for their compilation has involved the expenditure of a very considerable amount of time and trouble in the collection and arrangement of the data which we now publish. We have received the most cordial co-operation and assistance from all the leading manufacturers and agents in the kingdom. We are accordingly able to affirm, without fear of contradiction, that the "Guide" is as complete and comprehensive as it is possible for any table of the kind to be.

◆ ◆ ◆

Our Table Analysed—A Testimonial to the British Industry.

Incidentally, the figures and statistics which we have collected for the assistance of the prospective purchaser, provide a very fine testimonial to the growth and the increasing importance of the British trade. Out of the 498 cars which appear in our "guide," some 203 (approximately 40 per cent.) are entirely of British manufacture; 185 (37 per cent.) are French; some 18 (3·6 per cent.) American; 16 (3·2 per cent.) Belgian; and only 14 (2·8 per cent.) German, the remainder being made up of 9 Italian, 4 Dutch, and 3 Swiss vehicles. There remain some 41 composite cars, that is, cars of which the engine is manufactured in one country and the chassis built in another. Of these, 20 have British-built chassis fitted with French engines; 12 have French chassis fitted with British engines; and 9 have Belgian chassis, this country providing the motive power. Certainly two years ago, had we compiled similar statistics, the manufacturers of this country would not have been able to account for anything like 40 per cent. of the cars actually on the market.

◆ ◆ ◆

No More Unofficial Trials.

The Automobile Club has decided to put its foot down in regard to all unofficial car tests, trials and endurance runs of the kind that have from time to time been held under other than club auspices. We publish elsewhere the official notification to this effect, and we think the club is taking a wise course in the line it is adopting. It has established special machinery for enabling anyone who desires to do so, to have an official run with his car for as great a distance as he likes, and under exacting conditions, in regard to the *bona fides* of which no possibility of doubt can arise, since the trial is conducted under the observation of Club Observers all the time. The club, which is the leading "Society of Encouragement" in the country, is naturally the guardian of all records of what cars can do under test conditions, and it is wise in determining not to allow its authority to be usurped by any irresponsible individuals, however trustworthy and independent, who choose to get up a trial on their own account. Only official management and recognition by a body like the Automobile Club can prevent trials of this kind from degenerating into a farce, and if they are permitted *ad libitum*, farcical they are bound to become, sooner or later.

This is the same line of argument that we adopted, it will be remembered, in reference to the question discussed a considerable time ago as to whether private individuals, newspapers, and the like, should or should not hold reliability trials without the supervision and sanction of the club. The method by which the club prevented that being done, is now being adopted in the case of shorter trials. It proposes to disqualify any car owners or manufacturers who take part in them from all official trials or events held by the club. And this penalisation will, no doubt, prove effective in preventing the further spread of enterprises of the kind.

◆ ◆ ◆

A Little Less Expenditure Advisable. As the club is now taking over and assuming for itself a definite monopoly in the management and recognition of all trials of motor cars, we are glad to see that they are also taking into consideration the fact that this monopoly involves obligations. The existing tariff of charges for conducting an official trial are decidedly high. They do not mean much, of course, to the great manufacturers, but then, on the other hand, it is not the great manufacturers that are most in need of trials. It is the small, or at any rate, the newer firms that are most likely to desire them; and to many such, the present charges and fees are simply prohibitive. The club is, we thoroughly admit, wise in insisting upon a monopoly of car trials, and we are convinced that it is to the benefit of the industry that they should do so, but at the same time, under the circumstances, they must diminish the cost involved. Certainly, as a "Society of Encouragement," the club should not count upon making any profit out of them—rather the reverse, if necessary.

◆ ◆ ◆

An Ancient Horseless Carriage. A good deal of attention has very naturally been attracted by the instructive experiments that are being carried on at Aldershot by the Engineering and Aeronautical Section of the Engineers with Mr. Cody's man lifting kites, and it is therefore particularly appropriate to call to mind that what the kite can effect as a means of traction was fully recognised and actually employed in practice with very considerable success in the days when the old steam cars were first fulfilling the prophecy of Mother Shipton about carriages running without horses. Mr. Cody, it will be remembered, gave a demonstration of the tractive force of well-constructed kites a little more than a year ago, when he navigated a boat across the Channel, the motive power of which was supplied in this way. But much longer ago than this—about 1840 in fact—a light car propelled, or perhaps we should say drawn, by a team of kites, made a splendid run along the Bath Road. The machine was controlled by a powerful ground-brake, which brought it to rest when required, the kites, under those circumstances merely rising higher overhead and perhaps diving about a little eccentrically. The car itself was steered by a bicycle type of handle-bar, acting on a turn-table, and somewhat resembled a modern runabout type of motor car. In another column we produce an account of the very interesting experiments to which we refer, with illustrations depicting the kite-drawn car at full speed on the Bath Road, in fact, passing a coach-and-four, to the great fury of the driver of the latter, the admirers of the horse having in those days been even more hostile to mechanical locomotion, in any form whatever, than they have been latterly. The article we reproduce furnishes an interesting and instructive glimpse of the past, and affords a clear idea of the initiative, ingenuity, and comprehension of mechanical principles which characterised that very remarkable period, when those wonders of ingenuity, the old steam cars, had their birth, and when Faraday was first making his immortal pioneer experiments on the nature of electricity.

◆ ◆ ◆

The Training of Motor Drivers. The Motor Union continues to do good service in working for a more satisfactory state of affairs in regard to the training of motor car drivers. There have been some nice disclosures lately in the Press. The daily papers have borne witness to the existence of a number of institutions which are perpetually engaged in perpetrating one of the most cruel forms of the confidence trick—taking money from people who want to earn their own living and require badly to do so, and teaching them nothing in return. The fraudulent motor-driving school, in fact, is a cruel fraud on an aspiring class of the community, and is a detestable nuisance to the owners of motor cars, as well as instrumental in putting, we may say, into circulation—at any rate turning out into the world—a number of drivers provided usually with some sort of certificate, and more or less believing themselves to be competent, who would at once be sources of serious trouble to any establishment where they were regularly employed to drive and manage cars. The course which the Motor Union is adopting in order to grapple with the present situation is to arrange, if possible, for the establishment of *bona fide* institutions, where motor driving and motor car management will be properly taught, and with this object in view, the Secretary has addressed communications to the Town Clerks of Manchester, Birmingham, Southampton, Bradford, Liverpool and Cardiff, and also to the London County Council, inquiring whether these local bodies have taken any steps to provide facilities "for the training of mechanic drivers for motor cars, or to contribute to the cost of voluntary establishments having this object in view." The replies the Secretary has received up to the present show that a special class for motor car engineering has been established in Liverpool, though it is not designed to train drivers, but the authorities there are willing to consider any suggestions which the Motor Union has to make. The Clerk of the London County Council has explained, in reply, that the Education Committee of the Council consider that the best way in which such instruction should be afforded would be by the various polytechnics and similar institutions of the Metropolis, and they, too, are willing to adopt any suggestions the Motor Union may put forward.

⊛ ⊛ ⊛ ⊛

Royal Commission on Motor Cars.

THE Commission continued their sittings last week, and the following witnesses were examined:—Mr. John Drysdale and Mr. H. Hope, representing the Scottish Chamber of Agriculture; Mr. W. Henderson, representing the Perth County Council; Mr. J. Marr, representing the Highland and Agricultural Society; Mr. John Speir, representing the Glasgow Agricultural Society; Sir George Murray, Permanent Secretary to the Treasury; and Sir Henry Primrose, Chairman to the Board of Inland Revenue.

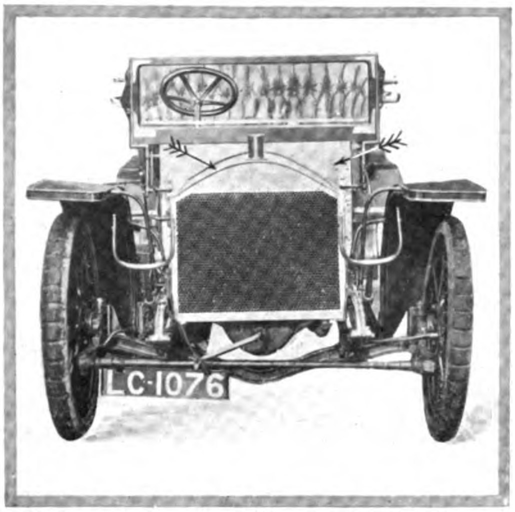
How to Recognise the Cars of To-day.

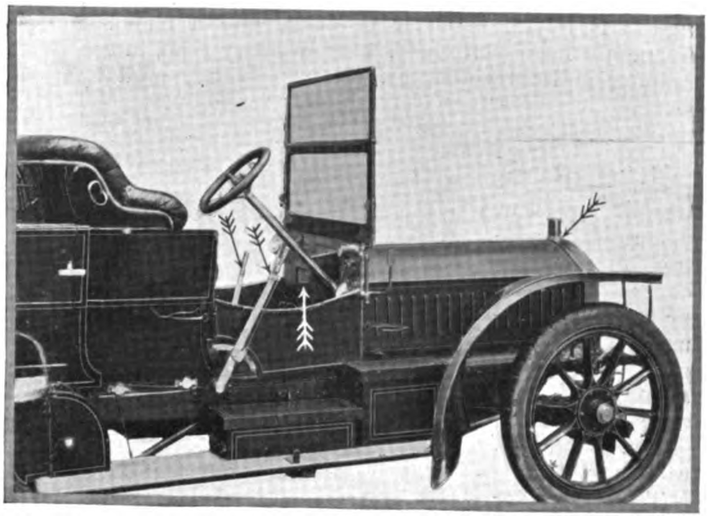
(No. 3).

The 6-cyl. Napier.

(BRITISH)

40 H.P. & 60 H.P.





The latest 40 h.p. and 60 h.p. Napier Cars—built in London—are live axle vehicles, but the earlier 40 h.p. model, which is still a standard type, is chain driven. Distinctive features are the comparatively narrow RADIATOR, with its numerous hexagonal tubes and tall filler-cap, the solid ALUMINIUM DASHBOARD, fitted centrally with its glass-fronted ignition box, and the plate-glass wind-shield with which these cars are usually provided. The CHANGE-SPEED and BRAKE LEVERS are also unlike those on other cars. (See "Automotor," Vol. XI., Jan. 13th to 27th, 1906).

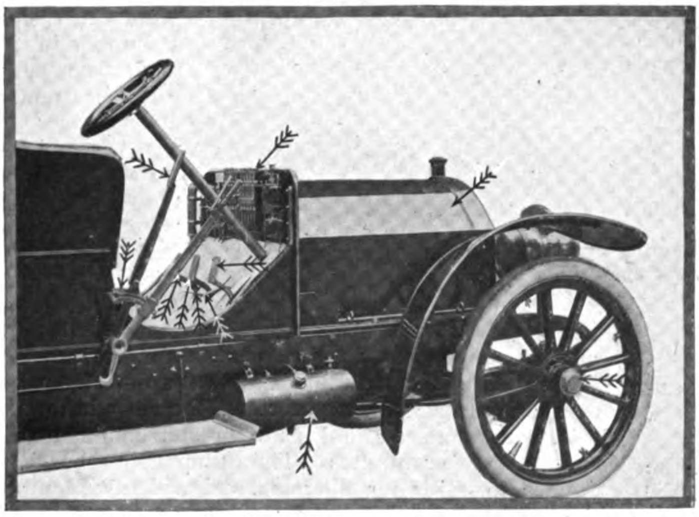
* * *

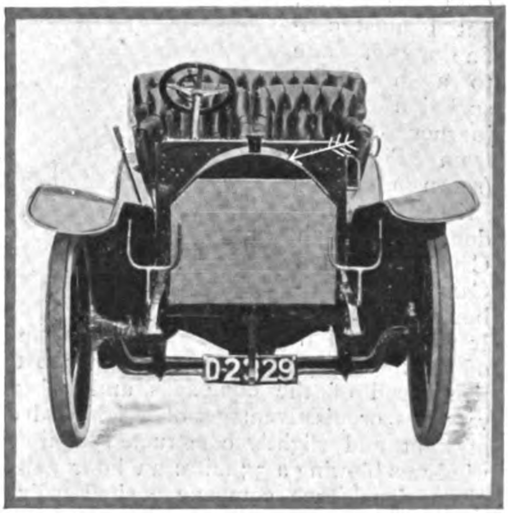
(No. 4).

The Mercedes.

(GERMAN)

20-25, 35, 45, & 70 H.P.





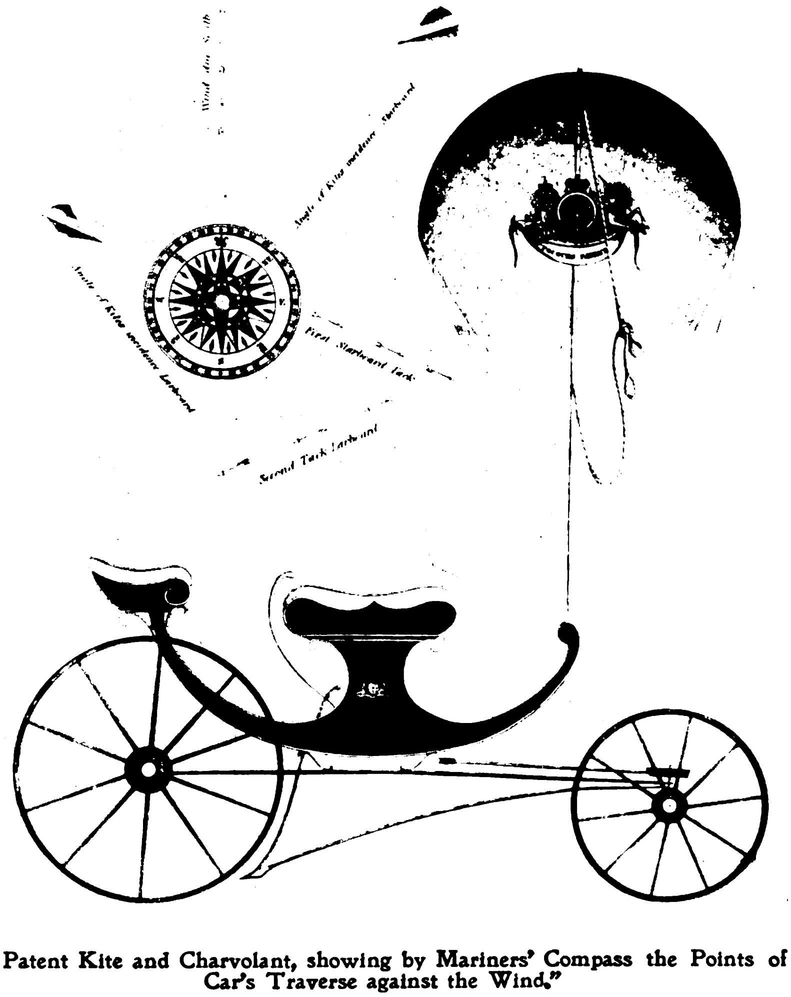
These German "Daimlers," which are entirely unlike the British Daimlers, are more easily recognised by their GENERAL APPEARANCE than by any particular detail, since many of their leading features have been copied on some other vehicles. Special characteristics are, however, the shape of the BONNET, the multiple-feed LUBRICATOR on the dash, the external PRESSURE TANKS fixed at each side of the frame, the GEAR LEVER, and the THREE LARGE PEDALS, as well as one or two small pedals. Usually the upholstery is in bright red leather, and invariably the "Daimler" name appears on the compact axle-caps. (See "Automotor," Vol. X., Sept. 30th and Oct. 7th, 1905).

TWENTY-FIVE MILES AN HOUR.

A Bath Road Record of Sixty Years Ago.

HAVING regard to the meagre speed limit for motors allowed by the Legislature, it comes as somewhat of a surprise to learn that nearly sixty years ago wild, untamed horseless carriages ran the highways at rates varying from 20 to 25 miles an hour. Mile after mile in succession, says the author of the little work beside me* has been performed at the rate of 20 miles an hour, timing it by chronometer in hand, and a mile has frequently been performed, over a heavy road, in two minutes and three-quarters. It may be supposed by some, he continues, that this celerity is dangerous — that it would prevent respiration, adding that it is certain the swiftness of the movement should almost prevent breathing if one were going against, instead of with the wind.

These wonderful journeys were performed in a "charvolant," or kite carriage, a lightly-built equipage to which are harnessed two kites, known as draught and pilot sail respectively. The book teems with marvels performed (or to be performed some day) by the kite, but I must confine myself here to a brief description of a journey made from Fig Hill (seven miles from Bristol) to London, through Chippenham, Calne, and Marlborough Downs. It was a trial trip, undertaken by three charvolants of varying size and draught power, "to test the relative speed of the equipages and to mark the advantages or disadvantages of weight and compactness, of light and slightly constructed equipments." The wind was blowing a 35 miles an hour gale, and at the given signal each company dashed gaily forward, the buoyant sails were unfurled, the canvas raised to the wind, and they were under way. We are in the heaviest car, with a pilot sail of 12 ft. and a draught sail of 20 ft., and up the steep ascent of Fig Hill we make the pace for the others; but, a downward incline reached, the lighter cars shoot ahead "with tremendous velocity." At the village of Ford, eight miles from the starting point, "we cast a rapid glance at our chronometer, and find our pace has been, up and down hill, at the rate of 25 miles per hour." The vane of the tall spire in Chippenham having been cleverly "manœuvred," the six miles to Calne is quickly covered, and "clearing every obstacle, we soon find ourselves on the edge of the High Chevil Downs, near Marlborough, our competitors advancing rapidly, but evidently two or three miles in the rear.



Wind due South
Angle of Kites windward Starboard
Angle of Kites windward Larboard
First Starboard Tack
Second Tack Larboard

"Patent Kite and Charvolant, showing by Mariners' Compass the Points of Car's Traverse against the Wind."

"About four miles from the edge of Chevil Downs" (the incident is worth recording *in extenso*) "we encountered a most unwelcome obstacle in a post-chaise and pair, which, though prime cattle, were a lumber in the road, compared with the tremendous pace we were then going— certainly not less than five-and-twenty miles an hour. The post-boy, however, determined to jockey us; he now traversed to the right, now to the left, of the road, just as he perceived we were about to pass him. We were thus effectually blockaded, at a time, too, when, to our great vexation, we perceived the party in the rear gaining upon us so rapidly as to threaten coming up with us in a very few minutes. The occupant of the chaise seemed to enjoy our dilemma, and evidently prompted the postilion in his clever manœuvres. At length, watching an opportunity, no sooner did a spot present itself where the downs sloped smoothly into the road, than the steersman dashed boldly out upon the turf, and, accompanied by the sound of the bugle, in one second our carriage shot ahead, and left our disappointed jockey in the rear. It may be mentioned here that since the withdrawal of the public conveyances from the turnpike roads a greater facility is afforded for the delightful recreation attending excursions in the charvolant, for miles may now be passed on many of our high roads without meeting a vehicle of any description, consequently scarcely any interruption occurs in this respect; indeed, in many places the grass is growing very luxuriantly, and the animals which formerly sweated and foamed whilst traversing these now old-fashioned courses might obtain a plentiful repast on the very ground which they were continually tearing up in their passage through the country.

---

* "The History of the Charvolant, or Kite Carriage," with illustrations, by David Cox, Jr. London: Longman, Brown, and Co., Paternoster Row, 1851.

"Night brought a dead calm, with not a breath moving amongst the leaves, but a steady and active breeze was flowing aloft, and a pace of about 18 miles an hour was maintained, the rapid movement demanding a vigilant lookout. The bugle was in frequent requisition and of essential service. After a delightful run we determined to close our day's adventures by bivouacking out till the dawn, in lieu of running into London. We accordingly furled our buoyant sails, reeled the cordage, and repaired to a stack of fragrant clover-hay, still in process of making. There, with our kites once more spread for an awning, and their oval ballast tails for a nightcap, we slept peacefully till awakened by the gay carol of the early lark." Thus abruptly ends the record of the trip.

"There the steersman boldly dashed out upon the turf."

It happened on several occasions, in the course of the writer's excursions, that they pulled up at a roadside public-house in the dusk of the evening, when the kites were hidden from view. Hearing the sound of wheels the ostler very naturally rushes out, probably from the lighted tap-room, to attend to his duties, and approaches, as he supposes, the head of our horse, but finds no trace of that moving power; his bewilderment is most laughable, and he hardly regards our order for some of the best Wiltshire beer. He scratches his head, but does not appear at all satisfied with his calculations as to our mode of travelling. After giving rather a doubtful glance at the occupants of our carriage he proceeds for the beer, and addresses the landlord with "Measter, a quart of beer for summat at the dooer." He appears again, and having recovered his first surprise, awaits with a credulous smile to see how we are going to move off. The beer being paid for, the drag is uplifted, the power line of the draught kite braced up, and dash goes the carriage, leaving the poor man to form his own opinion on the matter, which, we understood afterwards, resulted in the exclamation, "That if he had never zeed the devil afore he zeed un thic night, however."

I feel this article would not be complete without some description of the peculiarities in the construction of the charvolant, as set forth by the writer of the book. I use his words:—First. Before the charioteer is an upright spindle, surmounted by a T handle; the lower part of this handle, which runs through the bed of this car, is square, fitting into the socket of a small, solid, horizontal wheel, round which a strap passing communicates with another horizontal wheel, fastened to the pivot of the front axle-tree. By this apparatus, termed the "guide," the chariot is directed with the nicest precision. Second.—There is a regulator or drag in the hinder part of the car, suspended by a spring. The shoe of this drag is pressed by a lever power upon the ground, by which too great a velocity is prevented, or the vehicle instantly stopped, if requisite; this is effected without alighting. There are several minor appendages not common to other carriages, as a rule, and places for the chronometer, mariner's compass, &c. This car, having movable shafts, may be used with horses, precisely the same as other carriages.

That the vehicle could be stopped without alighting is certainly calculated to give the travellers confidence, but it is difficult to imagine how it would have been possible for the charioteer to dismount and stop the conveyance when it was running at the rate of about 25 miles an hour.

A Horse Ambulance.

Most people will have noticed the gallant effort being made to inculcate sympathy and affection for the horse, who is now being rapidly deserted by his former friends, made by the Society for Promoting Kindness to Dumb Animals. They have put upon the streets of the Metropolis an ambulance for horses, for conveying the unfortunate victims, that is to say, from the spot where they were injured, to a place where they can either be cured or put out of their misery. It is a nice substantial loose box, plentifully supplied with straw. We would suggest, however, that the proper motive power, under the circumstances, should be automobile. The automobile has shown itself in so many ways the true friend of the horse, that it is quite reversing the natural order of events to have the horse ambulance drawn by other horses. This is particularly the case, as rapidity in transport is sometimes of the greatest importance, and the superiority of the motor where human ambulances are concerned has been universally recognised.

THE NEW "XENIA" CARBURETTOR.

DURING the last two years the Xenia carburettor, which we described (on February 13th, 1904), in connection with the Crossley engines, has undergone considerable alteration. Then, it will be remembered, the principal feature was the automatic auxiliary-air-valve and its method of operation by the variation in level produced by the suction of the engine on a column of mercury.

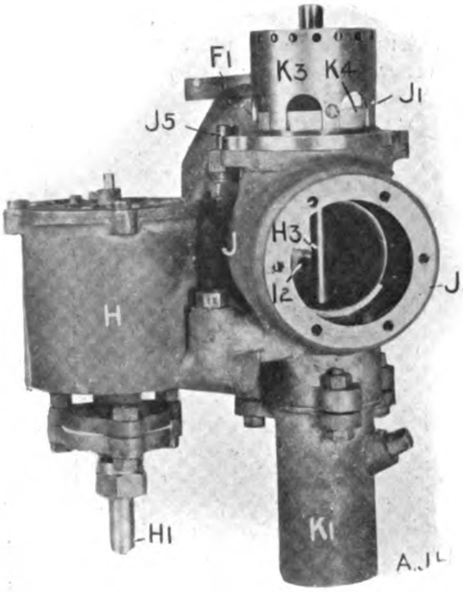

Fig. 1.—The Xenia Carburettor. View of the 1906 model, showing the automatic main air valve, K^4, which is interconnected with a variable petrol jet, and is controlled by the suction of the engine acting against the supporting effect of a float partly submerged in the mercury pot, K^1.

The whole principle has now been materially altered, although the use of mercury still remains as one of its characteristic features. This, however, is now merely employed for the purpose of providing a suitable liquid for supporting the float which controls—but no longer operates—the air-valve; the mercury device therefore constitutes a dash-pot pure and simple. Where the most important alterations have taken place is in the abolition of a fixed main-air port, and in the inter-connection of the variable air-valve—through which all the air now has to pass—with a variable petrol jet. This introduces an entirely new set of conditions, which resemble those governing the Bradley carburettor, although the details in the mechanical construction of the two devices are very different.

When running light, the throttle valve on the new carburettor is shut but the engine is able to draw the necessary supply of mixture to keep running through a small hole drilled in the valve itself. As the throttle-valve is opened, and the suction in the mixing-chamber increases, the main-air-valve is automatically drawn open and the effective size of the petrol jet enlarged. Whilst the air-valve is opening, however, it depresses the float in the mercury until the upward pressure just balances the suction of the engine.

One result of the modifications has been to considerably simplify the construction of the carburettor—as our illustrations very clearly show. For the convenience of our readers, the various corresponding parts are indicated by the same letters as were used in our previous description; consequently the two models can be the more easily compared by those who may desire to do so. In Fig. 1 the carburettor is shown complete, except that the plate which normally covers the large opening, J^2, has been temporarily removed in order to show the position of the jet in the mixing-chamber, and the "no load" hole, I^2, in the throttle-valve. Both the variable-air-valve, K^4, and the mercury dash-pot, K^1, are shown separately in Fig. 2, which also gives another view of the main body of the apparatus, after these members have been removed.

Petrol flows from the float-feed-chamber, H, into the mercury pot, K^1, and by covering the surface of the mercury prevents it from oxidising—a function which was performed previously by a layer of glycerine. From this chamber it ascends inside the hollow jet-spindle, H^2, to its normal level. There are several jet orifices formed by a series of fine holes, in each side of the hollow spindle, H^2, but for light loads the majority of these are covered by a tube, H^3, which surrounds the whole length of the jet-spindle. Cut in the tube, H^3, are two short slots, and it is only when the jet-holes come opposite to these slots that they are rendered operative. Directly beneath the jet-spindle, and supporting it, is the float, K^6, in the mercury pot, K^1. Resting on the top of the spindle is the air-valve, K^4, which is free to move vertically in its cage, K^3. Increased suction in the mixing-chamber—which is in more or less free communication with the induction-pipe, according to the position of the throttle-valve, I—tends to open the valve, K^4, thus admitting more

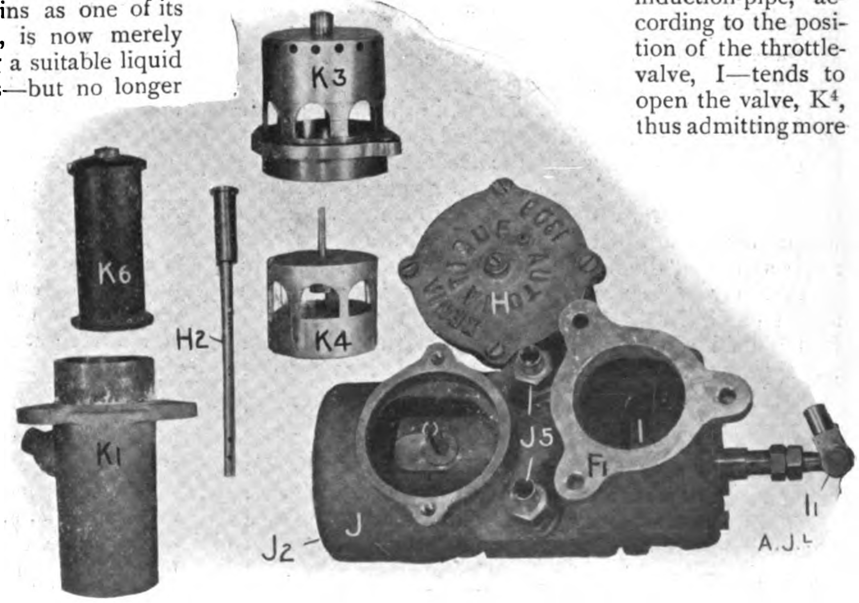

Fig. 2.—The Xenia Carburettor. View showing some of the more important parts of the carburettor separately. On the left is the mercury pot, K^1, with its float, K^6, and between these and the automatic valve, K^4, with its cage, K^3, is the variable petrol jet, H^2, which itself rests on the float and supports the valve.

air, and also tends to enlarge the effective jet orifice, thus correspondingly increasing the flow of petrol, so that a larger volume of correctly-proportioned " mixture " passes to the induction-pipe.

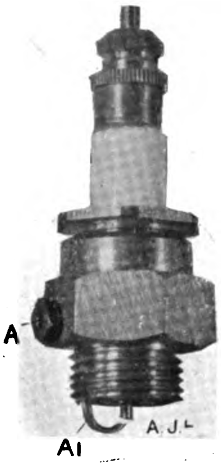
When necessary, the mixing-chamber can be warmed by coupling up its water-jacket to the circulating pump, unions, J^5, being provided for this purpose. It is also a simple matter to adjust the normal level of the mercury after removing the small plug fitted in the wall of the chamber, K^1.

Table of Reference Letters for the Xenia Carburettor.

F^1	Induction-pipe fitting.	J	Mixing-chamber.
H	Float chamber.	J^1	Main-air inlet.
H^1	Petrol connection.	J^2	Plate-covered end of J
H^2	Jet.	J^5	Water-pipe connections.
H^3	Needle-valve.	K^1	Mercury pot.
I	Throttle-valve sleeve.	K^3	Cover for K^4.
I^1	Throttle-valve rod.	K^4	Automatic valve.
I^2	Permanent hole in I.	K^6	Float.

⊗ ⊗ ⊗ ⊗

THE "E.C." IGNITION PLUG.

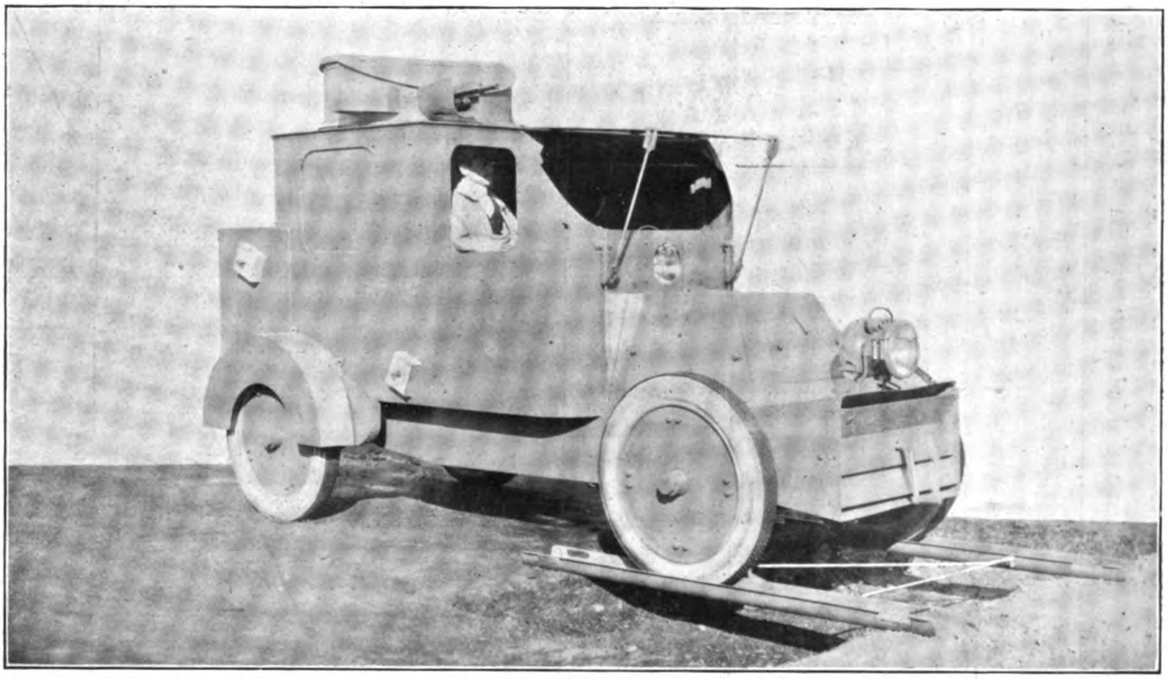


Inventors of ignition plugs are always careful to introduce some arrangement for the especial purpose of preventing permanent deposit on the sparking terminals, but usually this is confined to some characteristic in the general design which permits the gases in the cylinder to exercise a scouring action. In the " E.C." ignition plug, however, this automatic cleansing action is derived from a current of fresh air admitted to one of the hollow sparking terminals.

The orifice, A, through which the air is admitted, is visible in our illustration; it communicates with a narrow pipe, A^1, forming one of the sparking terminals, and it is provided with a small valve, which is intended to prevent loss of compression in the engine. This valve is merely a simple steel rod with a head on one end, and as there is no spring of any description it opens and closes atmospherically.

Motor Tower Wagon for Halifax Tramways.

The Halifax Tramways Committee have invited tenders for a motor tower wagon, to facilitate the work of attending to the overhead equipment of the tramways. New regulations introduced by the Board of Trade require that the installation shall be tested every six weeks. This, having regard to the extent of the system, would be impossible with the present horse tower wagon. The new wagon, which will involve less expense in upkeep than a horse-driven vehicle, is to be from 30–35-h.p. and is estimated to cost about £700.



Quite a number of Armoured Cars are now on order in France for the Russian Government, the first of these curious-looking machines being that shown in the above illustration. They are being built by the well-known C.G.V. firm, and the chassis employed for the purpose differs but little from that of their standard 30-h.p. touring model. Every part above the axles is completely encased in steel, the wheels themselves are built of steel, and provision is made by which the steel side windows as well as that in front of the driver's seat can be closed from within at short notice. Pneumatic tyres are employed, but these are said to contain a solution of some special kind to prevent rapid deflation, even if they should be pierced by a bullet, while spare tyres, fitted to spare wheels are carried in readiness for speedy replacement. Mounted on the roof is a quick-firing gun that can be pointed in any direction by one of the operators inside the car, and provision is made for carrying a large supply of ammunition, in addition to the five passengers. Loaded, and in full running order, the total weight of the car is about 3,000 kilogs., and it is geared to run at some 24 miles per hour on the level. The steel rails seen in the photograph are for enabling the car to cross ditches or to climb up low banks; usually, they are attached to the sides of the "body" by means of the fastenings designed for the purpose.

The AUTOMOTOR JOURNAL BUYERS' GUIDE TO THE TOURING AND PLEASURE CARS (PETROL AND STEAM) OF 1906, CLASSIFIED BY NUMBER OF CYLINDERS AND PRICE. (Copyright Registered.)

NOTE.—In certain cases the information available is so meagre that we have not felt justified in including such vehicles in this otherwise very complete table.

Buyers will find general particulars, enabling them to form a good all-round impression of each vehicle—such as price, speed, &c.—in the left-hand columns, under the heading, "Leading Characteristics." Other useful data are included under "Constructional Details" in order to assist purchasers to obtain more minute information. Cars have been classified, primarily, according to their number of cylinders—or the equivalent in the case of double-acting steam engines—and they have been further arranged, in each category, in order of price.

Leading Characteristics—
Drive.—S = Propeller Shaft; Sw = Propeller Shaft with worm drive; C = Single Chain; CC = Side Chains.
Engine—
Type.—D = Diagonal; V = Vertical; H = Horizontal.
Cylinder Capacity. — The figures in this column would denote the powers of the engines if 5,000 cubic inches suction = 1 h.p.
Ignition.—*b* = Battery; *m* = H.T. Magneto; *M* = Low-tension magneto. Brackets round either of these letters denote "fitted, as an extra, when required."
Fuel Feed.—*p* = Pressure; *g* = Gravity.
Lubrication.—*p* = Pressure Feed from lubricator to engine; *g* = Gravity Feed ditto.
Control.—G = Automatic Governor; H = Hand Control; F = Foot Control.
Transmission—
Clutch.—*lc* = Leather Faced Cone; *mc* = Metal Cone; *md* = Multiple Disc; *sd* = Single Disc; *ex* = Expanding; *sc* = Scroll; *dc* = Double Cone (leather and metal); *hy* = Hydraulic; *ba* = Band.
Change Speed Gear.—S = Sliding Spur; E = Epicyclic; U = Unusual.
Bearings—
P = Plain; B = Ball; R = Roller.
Dimensions—
Tyres.—*f* denotes that the front wheels are of different size.
Country of Origin—
B = Great Britain; F = France; Be = Belgium; G = Germany; I = Italy; S = Switzerland; H = Holland; A = United States; B, f = British Engine, French Chassis; B, be = British Engine, Belgian Chassis; b, f = British Chassis, French Engine.

The AUTOMOTOR JOURNAL BUYERS' GUIDE.

COMPARATIVELY little need be said by way of explanation concerning the various columns of figures and other data that constitute the comprehensive table of this year's cars that we publish to-day, especially in view of the fact that it has been compiled by us on practically identical lines to the "Buyers' Guide," which we issued in connection with the vehicles exhibited at the last Olympia Exhibition. It, of course, contains, however, particulars of a far greater number of cars than our previous table of pleasure vehicles, for that guide referred exclusively to the exhibits at the Show, whereas on the present occasion the tables contain practically every type of touring or town carriage that is now on the market in this country.

Primarily, as before, the cars are grouped together according to the number of single-acting (or equivalent double-acting) cylinders, while in each of these categories they are arranged in order of price, either by taking the price of the chassis or in certain cases that of the complete vehicle. Steam cars are in this manner placed amongst the numerous petrol cars; although the piston of a single-acting steam-engine receives an impulse *every* revolution instead of each *alternate* revolution—as with an ordinary petrol engine—this fact is neglected, and it is only a double-acting cylinder that has been taken as being equivalent to two cylinders of a petrol engine.

A glance at the headings of the various columns will show the prospective purchaser that the chief essential particulars are given at the left-hand side of the tables, under a special sub-heading. Here he can ascertain, without reference to any of the final foot-notes, the power, the normal top speed, the seating capacity and the price of each vehicle, while in a further column, also covered by the same sub-heading, are symbolic letters (explained in the footnotes) indicating whether the car has side-chains, a propeller-shaft, or other type of driving mechanism.

To the right of this more general information, are a large number of columns, in connection with some of which it is necessary to refer to the footnotes that are given at the end of the tables. These columns afford, in a condensed form, a practically complete specification of the car in question, including data concerning the type of mechanism employed, the dimensions of all parts that are of importance from that point of view, and such details as lubrication and ignition.

The chief novelties that have been introduced by us on this occasion are the final columns on the right-hand side of the tables, for in one of these we have been able, for the first time, to denote the country of origin of each vehicle, and in the other columns we have drawn attention—by giving a reference to volume and page—to the latest description that has appeared of each of the best-known cars in the back numbers of THE AUTOMOTOR JOURNAL.

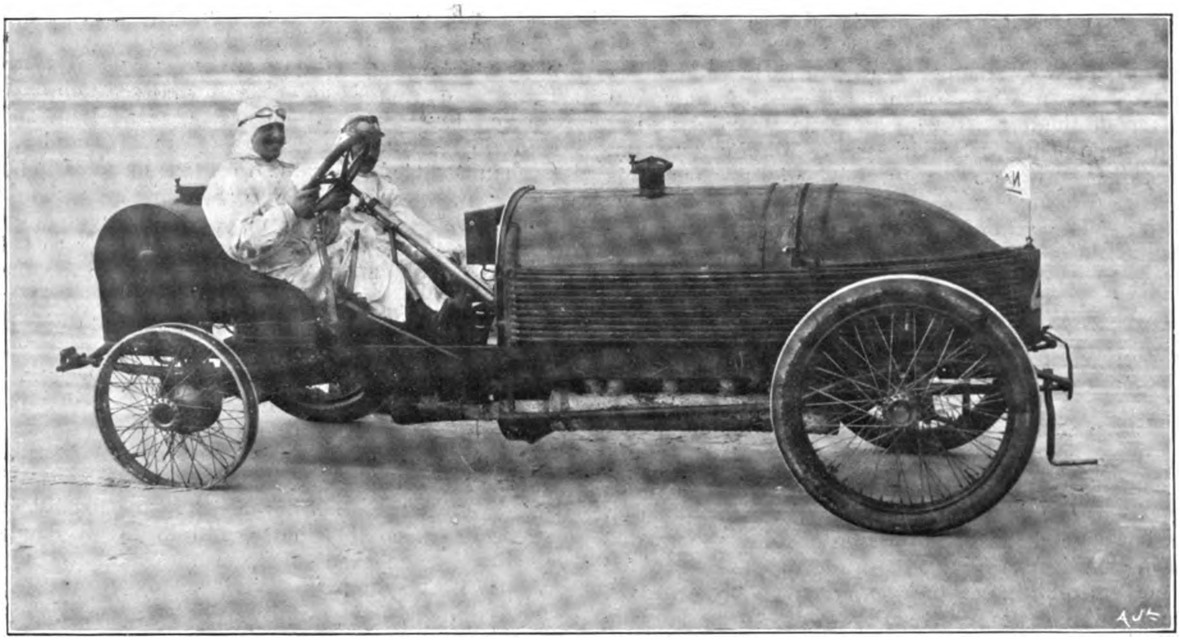
One useful piece of information is alone missing, so far as we are aware, from the Buyers' Guide, but this is of a character which we, as far as possible, avoid giving in our editorial pages, on principle. We refer, of course, to the absence of any of the addresses of the firms who manufacture or sell the vehicles in question. We are well aware that prospective purchasers desire to know where they can apply for further particulars of the cars they fancy, and where they can write when placing their orders, but we still adhere to what a few may think to be our old-fashioned views on this subject, and maintain, in spite of all "modern methods" of up-to-date *journalism* (save the mark), that the only proper place for announcements of this kind, is in the advertisement columns.

We have, however, in this special case, met the difficulty to some extent, and have adopted a system by which buyers using our guide can ascertain at a glance whether or not it will save their time to turn to the advertisement columns of this journal for this and other information. For this purpose, in the first column, the **names of all the cars** which are sold by firms who regularly insert business announcements in our pages, are printed in a thicker black type, while, in addition, we append below a supplemental list in which those particular vehicles are arranged in alphabetical order. In this list, moreover, we give the names of the firms in question, and we also devote a special column in which the leading characteristics of each make of car are briefly summarised.

Description.	Manufacturer or Agent.	Leading Features.
Ariel-Simplex, 35–40-h.p. ... ,, 20–25-h.p. ,, 15–18-h.p.	Ariel Motor Co. ... ... ,, ,, ,, ,,	One 6-cyl. and two 4-cyl. models, of the live-axle type, with "Mercedes" gear-boxes, and with the road wheels mounted outside the axle tubes. Metal-to-metal or leather cone clutches as required.
Argyll, 26–30-h.p. ... ... ,, 16–20.h.p. ,, 14–16-h.p. ,, 10–12-h.p.	Argylls, London ... ... ,, ,, ,,	All except the smallest model have Hele-Shaw multiple disc clutches. The change-speed-gear has its "second" and "third" speed gear-wheels always in mesh, the "first" speed only being of the sliding type. The pressed steel frame has a ∩-shaped section, and the standard bodies have pressed steel panels.
Arrol-Johnston, 24–30-h.p. ... ,, 12–15-h.p.	New Arrol-Johnston Co. ... ... ,, ,,	Both models are of the live-axle type, the smaller with a specially balanced 2-cyl. horizontal engine, and the latter with a 4-cyl. vertical engine. Both are fitted with a "spring-drive" device.
Austin, 25–30-h.p. ... ... ,, 15–20-h.p.	Austin Motor Co. ... ... ,, ,,	Quite new 4-cyl. British vehicles, the larger being fitted with live axle or with side chains as required, but the smaller having a live axle invariably. Engines have high-speed governors, and means for synchronising the igniters and valves whilst running. Disc clutches an d "Mercedes" type change-speed-gear.
Belsize, 30–40-h.p. ... ... ,, 24–30-h.p. ,, 18–24 and 10–12-h.p.	Belsize Co. ... ... ,, ,,	Engines with 2, 3, 4, and 6 cyls. Larger cars fitted with Hele-Shaw clutches instead of leather-faced cone clutches. All models have shaft-driven live axles and Panhard gear-boxes.
Berliet, 60-h.p. ... ... ,, 40 and 22-h.p.	J. E. Hutton ... ... ,,	A French make of car, similar in design to the "Mercedes" vehicles, except that the clutch is of the expanding metal-to-metal type.
Berna, 9–11-h.p.	Straker and MacConnell	A Swiss light car of live-axle type, with single-cyl. slow-speed engine.
Bianchi, 24–40-h.p. ... ... ,, 16–22-h.p.	Straker and MacConnell ... ... ,, ,,	Italian cars of the chain-driven type, with 4-cyl. engines and "Mercedes" type gear-boxes.
Brooke, 35-h.p. ... ... ,, 28 and 15–20-h.p.	J. W. Brooke and Co. ... ... ,, ,,	Both 4-cyl. models are chain driven, but the 6-cyl. car—which is quite a new model—has a shaft-driven live axle.
Cadillac, 9-h.p.	Anglo-American Motor Car Co. ...	A substantial American light car, with a single-chain drive from the horizontal engine and epicyclic change-speed-gear to the live axle.
Clement, 30, 24, 18-h.p. ... ,, 14, 12, 10-h.p.	Clement Motor Co.... ... ... ,, ,,	The differential countershaft casing on the 24 and 30-h.p. models is quite distinct from the change-speed-gear box, so that the general arrangement of engine and gear is similar on all cars. Multiple-disc clutches and gear boxes of the "Mercedes" type are, however, fitted to the larger models.
Crossley, 40-h.p. ... ... ,, 22-h.p.	Chas. Jarrott and Letts ... ... ,, ,,	Powerful chain-driven touring cars having 4-cyl. engines of British construction, fitted with "Xenia" carburettors. Expanding metal-to-metal clutches are used, and the steering gear has special features.
Cupelle, 18-h.p. ... ... ,, 10–12 and 6–8-h.p.	Cupelle Motors ... ... ,,	Light French touring cars, having live axles, and "Panhard" type gear boxes, 1, 2, and 4-cyl. models.
Daimler, 35-h.p. ... ... ,, 30-h.p. ,, 28-h.p.	Daimler Motor Co.... ... ... ,, ,, ,, ,,	Large, powerful 4-cyl. vehicles of the chain-driven type. Armoured wood frame, and the gear-box of special design, although operating on the Mercedes principle. Throttle and ignition controlled by a single hand lever above the steering wheel.
De Dietrich, 60, 40–50-h.p.... 24–30, 16–20, 12–15-h.p.	Chas. Jarrott and Letts ... ... ,, ,,	All models similar in general design, with 4-cyl. engines and side-chain drive. Specially-designed clutches of the leather cone type.
De Dion, 24-h.p. ... .. ,, 15-h.p. ,, 12-h.p. ,, 9-h.p. ,, 8-h.p.	De Dion-Bouton ... ... ,, ,, ,, ,, ,, ,, ,, ,,	All have cardan shafts to drive the road wheels, which are mounted on a stationary axle. Except on the smallest model, which has individual clutch in the gear-box, the change-speed mechanism is of the sliding spur-wheel type, and the main clutch is of the single disc pattern.
Delaunay Belleville, 40-50-h.p. ,, 28–32-h.p. ,, 20–24, 16–20-h.p.	Burlington Carriage Co. ... ... ,, ,, ,, ,,	Four-cylinder French cars of very substantial design in all respects. Those of higher power are chain-driven, but the small model is also made with a live axle.

Description.	Manufacturer or Agent.	Leading Features.
F.I.A.T., 24-40-h.p. ... „ 16–24 „ 12–16	Fiat Motors ... ... „ „	Chain-driven Italian cars similar in design to the German Mercedes, but with multiple disc clutches. All have 4-cyl. engines, including the 12–16-h.p. model introduced for the first time this year.
Germain, 35-h.p. ... ... „ 24-h.p. ... ... „ 16 and 14-h.p.	Capt. Theo. Masui ... ... „ „ „ „	On the larger models side-chains are used, but the entirely new 14-h.p. car has a live-axle. All the engines have four separate steel cylinders with brass water-jackets.
Gladiator, 30, 24, 18-h.p. ... „ 14, 12–14-h.p. „ 12, 10-h.p.	Gladiator Co. ... ... „ „	The larger 4-cyl. cars and the 6-cyl. model have multiple-disc clutches. Some are chain-driven, the chains being enclosed, others have live-axles. A feature of the suspension is the use of ¾ elliptic side-springs at the rear.
Humber, 16–20-h.p. ... ... „ 10–12-h.p.	Humber, Ltd. ... ... „	British cars of the live-axle type, with 4-cyl. engines. The rear wheels run on tubular extensions of the axle-casing, and the casing has a horizontal joint that facilitates thorough inspection.
Iris, 35–40-h.p. ... ... „ 25–30-h.p.	Legros and Knowles ... ... „ „	British vehicles with 4-cyl. engines. A special form of universal-joint is fitted to the propeller-shaft, the live-axle casing enables the differential-gear to be bodily removed without disturbing the axle. The throttle and the ignition are controlled by a single lever, and a dynamo automatically recharges the accumulators.
Maudslay, 30–40-h.p. ... „ 20–30-h.p. „ 16–20-h.p.	Maudslay Motor Co. ... ... „ „ „ „	The smallest of these chain-driven cars has a 3-cyl. engine, the largest is either fitted with a 4 or a 6-cyl. engine. All the engines have the cam-shaft arranged over the cylinders in such a way that it can be hinged back to facilitate the removal of the valves from above the cylinder-heads.
Mercedes, 70, 45-h.p. ... „ 35, 20–25-h.p.	Du Cros Mercedes ... ... „	These famous German Daimler cars are all of high power. They are chain-driven, have 4-cyl. engines, and are fitted with scroll clutches.
Napier, 60-h.p. ... ... „ 45-h.p. „ 40-h.p. „ 18-h.p.	S. F. Edge ... ... „ „ „	The 60 and 40-h.p. are 6-cyl. cars, the larger having a live-axle, and the 40-h.p. model being made either of that type or with side-chains. Metal-to-metal cone-clutches are fitted, except on the smallest vehicle, which is either built as a touring car or as a special landaulette of the "mock electric" pattern.
Oldsmobile, 20-h.p. ... ... „ 12-h.p. „ 7-h.p.	Chas. Jarrott and Letts ... ... „ „ „ „	The two higher-powered models are of recent introduction, designed on European lines, with vertical engines, sliding spur-wheel gears, cone clutches, and live axles. The smallest is a popular "runabout," with a single-chain drive to the rear axle, a horizontal engine, and epicyclic gear.
Panhard, 50, 35-h.p. ... „ 24, 15-h.p. „ 8–11-h.p.	J. E. Hutton ... ... „ „	The 8–11-h.p. is a 3-cyl. chassis, but otherwise all these chain-driven vehicles have 4-cyl. engines. Disc clutches are employed on the larger models. High-tension magnetos are fitted to all engines.
Regent, 18-h.p.	S. F. Edge	A medium-powered vehicle of German construction, built on orthodox lines, with 4-cyl. engine, Panhard type gear, and live axle.
Rolls-Royce, 30-h.p.... ... „ 20-h.p.	C. S. Rolls and Co. ... ... „ „	The largest is a 6-cyl. vehicle, and there are two distinct types having engines of 20 h.p., one being a 4-cyl. touring car, and the other a special 8-cyl. town vehicle. All are of the live-axle type.
Siddeley, 70, 32-h.p. ... „ 25, 18-h.p. „ 15, 12-h.p.	Wolseley Motor Car Co. ... ... „ „ „ „	These cars are made by the Wolseley Company and have vertical engines with either 4 or 2 cyls. Some have live axles and some are chain-driven; the latter have the differential counter-shaft casing separate from the gear-box.
Swift, 16–20, 12–14-h.p. ... „ 9–10, 7–8-h.p.	Swift Motor Co. ... ... „ „	Live-axle cars of moderate and medium power, fitted with 4, 3, and twin-cylinder engines, which are also of British manufacture.
Thornycroft, 36-h.p.... ... „ 24-h.p. „ 14-h.p.	J. I. Thornycroft and Co. ... ... „ „ „ „	All are of the live-axle type with multiple-disc clutches. The two smaller have 4-cyl. engines, but the larger is a 6-cyl. car only just introduced. On the smallest engine, the valves are all arranged above the cylinder heads.
Vinot, 35–50-h.p. ... ... „ 30–45-h.p. „ 20–30-h.p. „ 14–20 and 12–16-h.p.	T. J. Harman and Co. ... ... „ „ „ „ „ „	Chain-driven cars, all of which have 4-cyl. engines, except the most powerful, which has a 6-cyl. engine. The change-speed-gear is operated by a special type of mechanism, and some models have ¾ elliptic side-springs at the rear.
White, 18-h.p. ... ... „ 15-h.p.	White Steam Cars ... ... „ „	One of the very few thoroughly satisfactory types of pleasure vehicle propelled by steam. The more powerful new model enables any form of side entrance body to be employed, whereas previously all bodies were of the tonneau pattern.
Wolseley, 12-h.p ... ... „ 8-h.p. „ 6-h.p.	Wolseley Motor Car Co. ... ... „ „ „ „	Cars of moderate power, with horizontal, slow-speed engines. The two larger have twin-cylinder engines and side-chains; the smallest has a single-cylinder engine and a central-chain drive. A Renold silent chain transmits the power from the engine to the gear-box.

RACES, RECORDS, AND TRIALS.



ORMONDE-DAYTONA BEACH RACES.—In the issue of the "Automotor Journal" for February 3rd, we gave the chief results of this Florida Race Meeting, at which so many world's records were secured. Amongst these was the 100 miles, by Clifford Earp on his 6-cylinder Napier, in 75 mins. 40⅗ secs., which time was accomplished in spite of Earp having to run with three tyres only from the 35th mile onward. Our photograph shows Earp and his car immediately after the finish, none the worse for the gruelling he had experienced.

Unofficial Motor Trials.

We are officially informed that the Automobile Club, having in view the best interests of the public, and possessing an effective organisation for the express purpose of observing and reporting upon the actual performance of any car, is now taking definite action, in conjunction with the trade, to discourage unofficial trials, by preventing all cars taking part in such unofficial trials from entering or in any way taking part in any competition organised by or held under the auspices of the club, *e.g.*, like the International Tourist Trophy Race. At the same time the club is thoroughly investigating the question of cost to the entrant for an official trial, with a view to reducing the fees, if possible, now charged for officially observing and granting a certificate for a long-distance trial. The club desires to point out very strongly to the prospective motor buyer that its certificate of performance is a simple and accurate *record*, and in no way comments upon the performance of the car. A further point to be noted is that at the end of each day's run the car is delivered into the charge of the club officials, who thus have it under observation continuously.

Scottish Reliability Trial, June 13th–16th.

As a number of entries have already been offered, we have been asked to state that no entries whatever will be received except on the official forms, and these are not yet available. These forms will be issued to manufacturers and others, along with the rules and conditions, very shortly, and if any firms wish to ensure that their names are on the list, they should communicate with Mr. R. J. Smith, the honorary secretary of the Scottish Automobile Club (Western Section) at once.

Automobile Club Trials.

The following is a list of entries for the various trials received up to noon on Monday.

Tyres.

Collier Tyre Co., two sets; experimental set, entered through the Collier Tyre Co.; Hartridge Tyre Syndicate, solid rubber block tyres fitted to a 'bus chassis.

Cars.

24-h.p. Dennis.

Speedometers.

"Vulcan" (Geipel and Lange), Staunton and Co., Elliott Bros., "Jones" (S. F. Edge, Ltd.), "Gratze" (S. F. Edge, Ltd.), experimental (R. B. Kirby), Cowey Engineering Co., Ltd., "Werner" (Selig Sonnenthal and Co).

Lamps.

Tail lamps—Ryta and Hoult Trading Co., The Metallic Mirrors, Ltd., Worsnop and Co.

Head lights—Gas, Worsnop and Co.; paraffin, George Polkey, Ltd.

To Climb Frome's Hill.

Competitors in the Hereford small car trials will recollect the severe test which climbing Frome's Hill inflicted upon many of the low-powered cars. The Herefordshire A.C. have now decided to hold an open competition for cars on this hill, probably in May next.

The Grand Prix.

It seems fairly certain now that this French race will be run on June 26th and 27th, and that the entrance fee will be 5,000 francs per car.

Starting for the second day's race will be arranged so as to practically make this a *continuation* of the first day, by starting each car at the same intervals of time which existed between them respectively when they finished the day's racing on the first day. In the event of any car being 3 hours to the bad behind the best car on the first day, the driver will not be allowed to start on the second day.

Los Angeles to San Diego.

ALL-ROUND success attended the first endurance run between Los Angeles and San Diego on January 25th and 26th. The distance was 180 miles, spread over two days, a halt being arranged at Elsinore, 80 miles out, on the first night. Rough roads and big mountain climbs made the test a severe one, the second day's run to San Diego being particularly trying in hill negotiation. Three ridges had to be surmounted, and a few accidents from over-speeding were recorded, but nothing of serious moment. The sensation of the meeting was the performance of the White steam cars, one of which, driven by C. A. Hawkins, of San Francisco, secured the Cup in the big touring car class, beating G. F. Belden's 1906 Packard by nearly three gallons of fuel—both cars scoring the full 1,000 marks. In the light touring car class the Cup was awarded to a 1905 model Ford car, which lost only one mark, the Gasoline and Economy Prize Cup going to F. A. Bennett's car of the same make. R. C. Hamlin's Franklin car was first in the runabout class, losing 25 marks on account of hills and tyres. The Maxwell cars were high up in the running, but were disqualified for transgressing the regulations in regard to carrying advertising signs. Four White steamers, in addition to the winner in the big car class, three of which were driven by private owners, were awarded first-class certificates, losing one, two, and three points only respectively.

Anti-skid Competition Abandoned.

IT has been decided by the A.C. Seine-et-Oise *not* to hold their anti-skid device competition this year, in consequence, it is stated, of the deposit of 500 francs required by the A.C. de France towards the expenses of the Annal "Calendrier," before official recognition of the event can be accorded. We recently drew attention to this new idea of the French Club.

Havana Race Meeting.

SEVERAL of the Continental drivers took part in the Havana meeting which commenced on Monday last, when the main attraction was a race over a distance of $217\frac{1}{2}$ miles. A road measuring 54·37 miles between Havana and San Cristobal was selected, which had to be covered four times. Four started, viz., Lancia (Fiat), Cedrino (Fiat), Demogeot (Darracq), and Bernin (Renault). Cedrino came to grief in rounding a bad corner and had to give up; Lancia's mechanic was thrown from the car and broke his leg, Lancia himself subsequently abandoning the race in order to help his companion, Cedrino. Bernin, who led in the first lap, covered the 54·37 miles in 51 minutes. Demogeot lost eight minutes at the start, but made up five of this on the first round, his time being 54 mins. 26 secs., against Bernin's 51 mins. 4 secs. On the second round he took first place with 1h. 45m. 32s., against Bernin's 1h. 53m. 44s., and maintained his speed until the finish, securing the race with his 200-h.p. Darracq in 3h. 38m. $18\frac{4}{5}$s. The arrangements for the race were in the hands of the Cuban Government, who had told off 550 soldiers to keep the course, and President Palma personally attended the races, accompanied by the members of his Cabinet.

A Spanish Motor Run.

IN honour of the marriage of the King of Spain with Princess Ena, in June, the leading Spanish automobilists propose organising a motor run between Barcelona, Saragossa, and Madrid, a distance of about 650 kiloms.

Nice Meeting.

AUTHORISATION has been given for the motor speed events to take place at Nice next month. In addition to the mile and kilometre, there will also be a hill climb of about 9 kiloms. on the Turbie road.

MOTOR CYCLING.

Land's End to John-o'-Groats.—This event of the Auto Cycle Club bids fair to be one of the most interesting trials ever promoted for motor cycles, and already entries are being received from those manufacturers desirous of taking part in same. It has been suggested that it would be desirable to place a limit on the number of entrants, and those who intend entering will do well to consider the advisability of sending in their names at the earliest possible moment, as this not only guards against their being shut out of the trial, but it considerably facilitates the organisation, which, in such a trial as this, is no small matter. Manufacturers, and also private owners, who intend entering should therefore communicate with the Secretary, Auto Cycle Club, 18, Down Street, Piccadilly, W., as early as possible.

Motor Cycling Club.

THE following is the programme of special events for 1906:—

March 31st.—Opening run to Brighton.

April 13th.—Easter tour to Yeovil.

May 5th.—Two hill-climbing competitions (motor cycles only), run as separate events, one confined to private owners.

May 19th.—Brown 50-guinea Challenge Cup for cars the private property of member driving.

June 1.—London to Edinburgh 24-hours' run, open to cars and motor cycles.

June 23rd.—100 miles non-stop trial for motor cycles, private owners only.

July 7th.—200 miles non-stop trial for motor cycles, private owners only.

July 28th.—Reeves Challenge Cup, 200 miles reliability trial for motor bicycles.

August 25th.—International team competition for motor cycle Challenge Cup.

Sept. 15th.—Passenger trial competition, motor cycles only.

,, 29th.—Motor cycle petrol consumption trial.

River Hill Open Event.

OF the 35 motor bicycles and tricars entered for the Lewisham A.C.'s open hill climb on River Hill, Sevenoaks, last Saturday, mainly owing to the very bad weather conditions, only 17 actually started. The road surface required considerable care on the part of the competitors to avoid some nasty sideslips. As is now customary, no times are available, an "order of merit" only being officially issued. These results of the handicap for each class in handicap order were as follows:—

Motor bicycles (10 starters).—1. F. J. Ellis, $2\frac{3}{4}$-h.p. Matchless (single-cylinder De Dion engine 76 × 76 mm.).

2. L. W. Bellenger, $3\frac{1}{2}$-h.p. Quadrant (single-cylinder Quadrant 81 × 88 mm.).

3. O. C. Godfrey, 4-h.p. Werner (2-cylinder Werner 60 × 88 mm.).

Bellenger made the fastest actual time.

Tricars (7 starters).—1. W. Gunn, 2-cylinder 10-h.p. Lagonda, 90 × 96 mm.

2. W. P. O'Reilly, 1-cylinder C.I.E., 4-h.p. 80 × 85 mm.

3. T. A. Read, 2-cylinder 9-h.p. Singer, 86 × 90 mm.

Gunn made fastest actual time.

Turin Motor Cycle Race.

ON Sunday last the 60 kilom. race for motor cycles on the Turin-Pino-Chieri-Villanova road resulted as follows:—1. Rigat, 51m. 15s.; 2. Voarino, 1h. 2m. 4s.; 3. Bellorini, 1h. 5m. 10s.; 4. Battagliotti, 1h. 6m. 40s.; 5. Lorenzetti, 1h. 14m. 11s.

CLUBS AND ASSOCIATIONS.

Essex Motor Club.

THE annual general meeting of the above club was held at the headquarters of the club, Castle Hotel, Woodford, last week, Mr. W. H. Bishop, the honorary solicitor of the club, in the chair. The report and balance-sheet which the committee and secretaries were enabled to submit to the members showing a strong financial and social position.

Among the important business of the meeting was the changing of the name of the club from that of the "Essex Beaumont Motor Club," to the "Essex Motor Club," by which latter name it will be known in the future.

The new committee elected comprised: Messrs. Lowe, Prentice, Horswill, Richards, Norris, and Macdonald. *Captain*, Mr. Owen L. Summers; *Riding Officer*, Mr. G. E. Revell; *Secretaries*, Messrs. A. George Reynolds and Ernest J. Bass. *Hon. Solicitor*, Mr. W. H. Bishop. *President*, Mr. Arthur Du Cros, J.P.; and *Vice-President*, Mr. Fred Pluck.

The secretaries announced that they were in hopes of promoting a competition, now that cars were getting numerous in the club, for cars alone; in addition, they were working out, amongst other competitions, a 150-mile non-stop, to take place in Essex.

Herefordshire A.C.

AT the annual general meeting of this club, held at the Mitre Hotel, Hereford, when Mr. J. T. Hereford presided, the hon. secretary and treasurers' report showed a balance of £25 6*s*. to the club's credit, with no liabilities.

Col. Hopton was elected president for 1906, and the names of Col. Scudamore and Mr. J. H. Bailey were added to the vice-presidents who were re-elected. The whole of the committee were re-elected, with the addition of Mr. S. Butt-Ekins, who has promised to act as assistant hon. sec. to Mr. Wilfrid Groom, who was re-elected hon. secretary and treasurer.

Hertfordshire County A.C.

AT the annual general meeting of the Hertfordshire County A.C., the fusion of the West Herts Motor Club was confirmed.

The retiring chairman, Mr. Noel B. Kenealy, presided.

The report and accounts of the past year were submitted and passed, and willingness to serve as follows on the part of several distinguished members was announced:—

The Right Hon. the Earl of Clarendon, president, and as vice-presidents: H.S.H. Prince Louis of Battenberg, the Right Hon. the Earl of Verulam, Lord Hyde, Sir Charles Forbes, Bart., Lord Essex, Lord Malden, and Dr. Lovell Drage.

The committee was enlarged to fourteen members, of whom Mr. Charles McWhirter was elected to the chairmanship for the coming year.

Motor Union Provincial Meetings.

THREE meetings of the Union in the provinces have been been fixed for 1906, viz., May 26th, at Birmingham, July 21st, at Bath, and September 22nd at York. The programme of arrangements locally is being left in the hands, respectively, of the Midland, Somersetshire and North Yorkshire Clubs.

An Imperial Organisation.

A CONSIDERABLE number of motorists in the Colonies and British dependencies are now joining the Motor Union, and are thus extending its influence and powers of being useful in other lands. The Union has members in Malta, Australia, New Zealand, Cape Colony, India, the West Indies, West Africa, and elsewhere. Last week, two applications for membership were received from India, and one from the Transvaal. Mr. A. E. Lamb, chief of the Hansard staff in the Transvaal, in forwarding his application for membership from Pretoria, has offered to cordially co-operate with the Union or the A.C.G.B.I. in connection with obtaining information with regard to motoring in that part of the Empire.

Motor Yacht Club.

"ENCHANTRESS" is the London telegraphic address of the club.

Wolverhampton A.C.

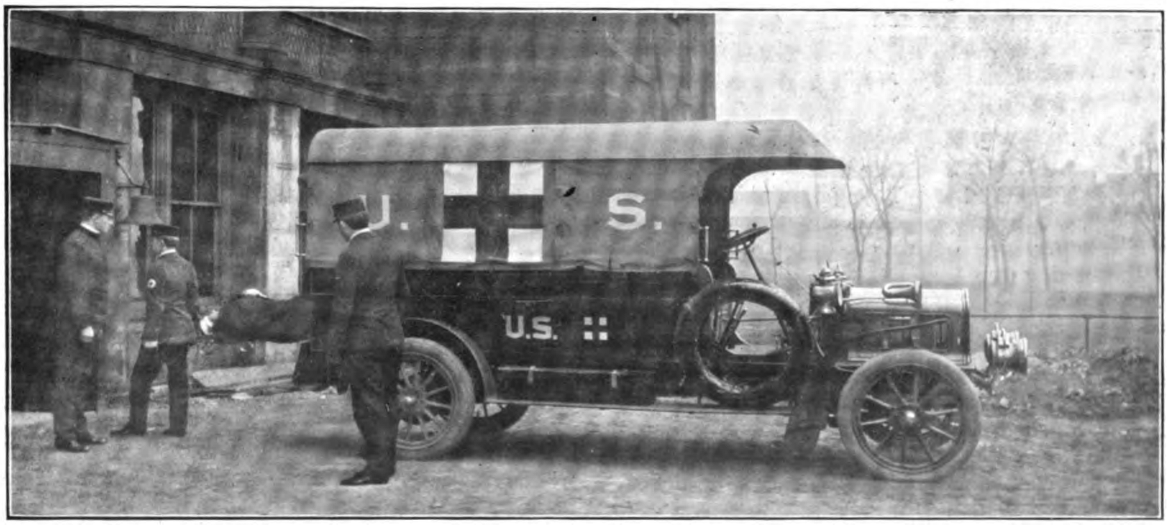
AT the annual general meeting of the club, when Mr. E. Lisle, the president, occupied the chair, the report and accounts, which were highly satisfactory, were unanimously passed.

The following officers and members of committee were elected:—*President*, Mr. T. Cureton. *Vice-Presidents*, His Worship the Mayor, Captain Burnett, Messrs. J. H. Cooksey (Town Clerk, Bridgnorth), J. O. Evans, T. T. Mills, W. G. Owen, and T. F. Young. *Treasurer*, Mr. G. H. Evans. *Secretary*, Mr. S. R. Rhodes. *General Committee*, Messrs. F. C. Bishop, Fred Bayliss, J. W. Davis, W. H. Evans, T. G. Gatis, T. Lisle, A. W. Moore, and H. W. Stroud.

For the purposes of affiliation with the Motor Union, it was decided to divide the club into (a) An Automobile Section (b) A Social Section, and resolved that the former section should join the Union.

Aero Club.

AT the last meeting of the committee the following were elected members:—The Lord Aberdour, Lady Aberdour, Miss Elsie Owen, Capt. W. A. de C. King, R.E., Lieut. W. T. Caulfield, R.E., Mr. Vere Ker-Seymer, Mr. J. St. John Gore, Mr. A. B. Randolph, Mr. G. Lloyd Jones, Mr. Codrington Crawshay, and Lord Royston.

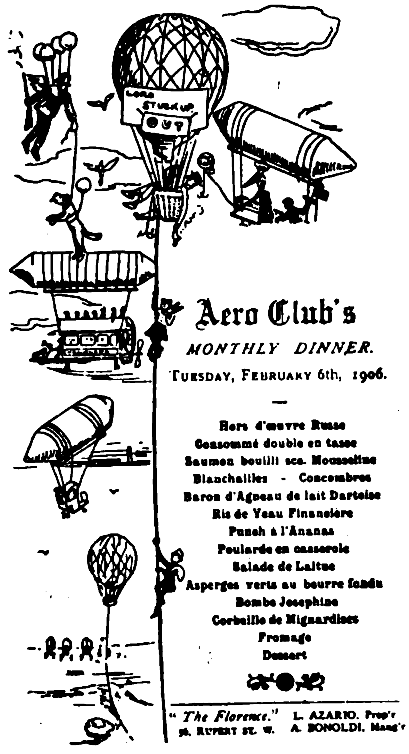


As in the British Army, so motor ambulances are now receiving attention in America for forming part of the regular ambulance corps. The first built to the order of the United States Army is seen in our photograph, and is a standard 18-h.p. White Steam Car with lengthened wheel base measuring 10 ft. 8 in. Plenty of room is thereby provided for carrying the wounded. Altogether the White cars have from the first found much favour with the American military authorities. Three of this type, it will be remembered, were used in 1904 by General Corbin, during the extensive manoeuvres held at Bull Run, and again last year four "Whites" were employed in the manoeuvres of the Massachusetts State Militia.

AERONAUTICS.

The Aero Club Dines.

COMMENCING with February, the Aero Club of Great Britain and Ireland have instituted regular monthly dinners, where it is hoped the interests of the movement will be considerably helped, as discussions naturally follow the banquets and new recruits are enrolled. The first dinner took place on February 6th, and we reproduce the humorous menu used for the occasion. Amongst those present were the chairman, Mr. Roger W. Wallace, K.C.; Professor Huntington, of King's College; Colonel Capper, C.B., R.E., Director of Military Ballooning; the Hon. C. S. Rolls; Mr. T. C. Aveling, of the Midland Automobile Club; Mr. Patrick Alexander; Mr. Frank Butler; and also Messrs. Pollock and Dale, who recently crossed the Channel in the club balloon.



Aero Club's

MONTHLY DINNER.

TUESDAY, FEBRUARY 6th, 1906.

—

Hors d'œuvre Russe
Consommé double en tasse
Saumon bouilli sce. Mousseline
Blanchailles - Concombres
Baron d'Agneau de lait Dartoise
Ris de Veau Financière
Punch à l'Ananas
Poularde en casserole
Salade de Laitue
Asperges verts au beurre fondu
Bombe Josephine
Corbeille de Mignardises
Fromage
Dessert

"*The Florence.*" 56, RUPERT ST. W.

A. BONOLDI. Manag'r

Humorous Menu Card of the First Monthly Dinner of the Aero Club.

Flying Machine Experiments at Aldershot.

IT will come as a pleasant surprise to many people in this country interested in the problems of aeronautics, to find that the experiments which the military authorities at Aldershot have been carrying out recently, go a great deal further, and are of a more interesting character, than the mere tests of Mr. Cody's man-lifting kites, to which we recently referred. In fact, a large number of instructive gliding experiments appear to have been conducted under the supervision of Mr. Cody and Col. Templer, who is the moving spirit both of the Military Ballooning and Aeronautical Departments, and of the employment of mechanical traction for army purposes. An apparatus has been constructed, we understand, very similar to, if not identical with, the Wrights' aeroplane, which in Aldershot is known by the general nickname of "The Glider." It consists, that is to say, of two superposed aerocurves with guiding appliances, and, as in the Wrights' aeroplane, the aeronaut lies prone in the middle of the lower wing. This apparatus has been taken up by kites, and released at heights of as much as 500 ft., when long and thoroughly successful glides have been carried out with it, Mr. Cody in one case making a record glide of as much as half a mile, while a number of the engineers have also experimented with it, and, though not travelling distances as great, have manipulated it perfectly, and in every instance come to the ground without damage or injury of any kind. The "Glider" has not, of course, always been taken up as high as 500 ft., but in some cases, presumably with suitable opposing winds, experiments of, we believe, a not less successful character have been made from the tops of hills.

A Credit to the British Army.

EXPERIENCE and practice in controlling the gliding machine is, as we have always pointed out, most important, if not absolutely indispensable, for acquiring the necessary dexterity, skill, and self-possession for managing the motor-driven flying machine. It is most satisfactory to learn that the special department of the British Army, which concerns itself with such matters, has been plodding steadily along, and making real and substantial progress. To have a number of engineers who have executed free glides in this way, is to have a body of men who will be far ahead of any other experimenters, and probably be able to learn, with much less difficulty than anybody else, the mysteries involved in managing the flying machine of the future. While there has been a lot of talking and writing by people who have done nothing of a practical kind, here we have the British Army working away silently and unobtrusively, without attracting any public attention, in the way best calculated to lead to an ultimate solution of the flying problem. In fact, these Aldershot experiments are, as far as we are at present able to judge, ahead of anything that has been accomplished except by the Wright Brothers, and would seem to be even as good and as triumphant as anything which they had accomplished prior to the autumn of 1903. Of course, with a controllable machine it is probably not so difficult a feat to glide half a mile from a height of 500 feet, as it was in the Wrights' case to glide 300 yards from the top of a sand hillock. It may not necessarily involve quite such complete mastery of the machine, but it does show that effective mastery has been attained. In fact, that is effectively shown even by the shorter glides. A man who can keep an aeroplane of this kind from turning turtle and coming to the ground with a crash, will not, we fancy, be very long in learning how to control a motor-driven machine.

To Avoid Breaking Bones.

VARIOUS proposals have been put forward as regards suitable sites for gliding experiments. M. Archdeacon, in France, it will be remembered, regarded the sand dunes of Berck-sur-Mer, near Boulogne, as the most ideal spot with which he was acquainted. We ourselves suggested the South Downs (particularly in the neighbourhood of Worthing) and now Lord Montagu observes that he is the proprietor of 6 miles (? 6 square miles) of the softest mud on the Solent, covered with a few inches of water when the tide is up, and this he thinks would furnish an ideal experimenting ground, since however forcibly the experimenting aeronaut descends into it, he can hardly be seriously hurt. This is no doubt the case, and probably the experimenter will escape fracture of any of his limbs. But if he descends from 40 or 50 ft. in the air head first into Lord Montagu's soft mud, it is a very doubtful question whether he can be extracted even by the most enthusiastic assistants before suffocation has put an end to his experimenting further, even if the said assistants could get at him without being swallowed up in the nice soft mud themselves.

On the whole we rather suspect Lord Montagu of having a little fun with ourselves and others who have been enthusiastic on aeronautical topics. It is perhaps his delicate way of pointing out that the *place* where experiments are conducted is not of so much importance as the *way* in which they are carried out.

Official Recognition of the Lebaudy Airship.

The Lebaudy airship has for a long time been, *de facto*, a part of the military equipment of France, and now the full formalities have taken place, and the position of the airship among the defences of the country has been formally recognised by the military authorities.

The Military Aspects of the Situation.

At the same time, as we have already chronicled, the Brothers Lebaudy are constructing another airship on almost identically the same lines as the great machine now reposing at Toul. If anything, it will be slightly larger and more powerful, though not much, and the French Government has already contracted to take delivery of it on its completion, which, it is anticipated, will be within about six months from the present date. The French Government obviously has in view a programme which will have the effect of providing each of the great frontier camps and principal fortresses with one of these splendid scouting appliances. If ever war takes place on the French frontier, there can be little doubt that admirable service will be rendered by these vastly improved "eyes of the army," and that the first series of actions will be, to some slight extent, similar to the battle of the air foreshadowed in Mr. H. G. Wells' "Anticipations," to which we have frequently alluded. It will not be quite the same, for the French airships will, as far as can be judged at present, have it all their own way, the possible enemy across the Rhine not having, so far as is known, distinguished himself in the conquest of the atmosphere. The situation, as it exists at present, is a triumph for French technology. No other people seem to be able to build airships of the navigable balloon type that will hold their gas for a sufficient time to be practicable, and be thoroughly manœuvrable at the same time, whilst developing a speed of practical utility.

1907 Developments.

M. Julliot, the able and universally famous constructor of the Lebaudy airships, is getting out a new model to surprise the world in 1907. It is to be more powerful and considerably speedier than the present "Lebaudy," and alterations in the arrangements of the firm are being organised in connection with it. Hitherto, as our readers are aware, the whole of the airships have been constructed at Moisson. In future, however, the mechanical portions, *i.e.*, the hull, the motor, the propellers, &c., are to be built in Paris in the workshops attached to the Lebaudy sugar refinery in the Rue de Flanders. The gas-vessel is to be constructed, and the final assemblage of the airship is to take place, at Moisson.

A Similar Machine for Great Britain.

The enthusiastic aerial department at Aldershot, to whose experiments in aeroplanes we have drawn attention above, is also arranging to build a machine, on what may be regarded as the Lebaudy lines, for military purposes in this country. The British airship will be an imposing affair, the gas vessel being 132 feet in length and 25 feet in diameter with conical ends, and will contain some 70,000 cubic feet of hydrogen. It will have a lifting capacity of over 3 tons. The skin of the gas-vessel is to be made of a number of layers of gold-beaters' skin, which, it is said, will be particularly able to withstand any tendency to cracking or tearing. The hull, which is more like the Santos-Dumont type than that of the Lebaudy airship, is to be provided with motors developing 40 h.p., and these will drive propellers at both ends, while the tests already made lead to the conclusion that a speed of 25 miles an hour will be attainable.

The race towards perfection between the navigable balloon type of machine and the aeroplane, which people living at the present day are privileged to witness, is probably the most interesting competition in the development of man's control over the forces of nature which the world has yet seen.

More Doubtful Methods.

We last week reproduced a photograph of the Hamilton aeroplane, which has given such a sorry account of itself on the Florida Beach, and pointed out some of the reasons which, in our opinion, were among the causes of its want of success. A little previously we referred to the experiments of Mr. Ellehommer in Denmark, and M. Vuina near Montesson. From information which we had received in regard to the performances of the Danish experimenter, we believed, and stated, that he had actually executed free flight through the atmosphere, even though only for a distance of 50 metres. Since then further details of his machine have come to light, and, though we would not like absolutely to deny the possibility of its having left the ground for a short distance, we feel quite convinced that a machine of this type is not at all likely to accomplish sustained satisfactory free flight. It consists essentially of a central arch of canvas, or similar material, on either side of which are stretched two big wings. A propeller is mounted in front of the arch, where it is supposed to develop the necessary propulsive force, and the whole arrangement is mounted on quadricycle wheels. That this arrangement could succeed in carrying an aeronaut on a quadricycle any distance, we find it difficult to persuade ourselves to believe, as also that it could be successfully manipulated in the air for any length of time.

We may in general make the same observations in regard to the Vuina machine, which also simply consists of a quadricycle with motor and propelling mechanism and large wings, the shape of which suggests a cross between a bat and an ordinary umbrella.

The chief difficulty with constructions of this kind is that the prospects of attaining real rigidity with the wings are more than problematical. In the Wright and Chanute type of machine the two surfaces or aerocurves are tied and strutted together, and the whole produces a compact and rigid structure. Not so with the expanded bird-like wings. To give them anything like the same degree of rigidity, a complicated system of vertical rods and ties extending above and below the wings appears an absolute necessity, and that is handicapping the machine most seriously.

* * * *

Twenty Years' Horseless Carriages.

On Wednesday last a very interesting paper on "The Horseless Carriage, 1885–1905," with numberless illustrations, was read by Mr. Claude Johnson, at the Society of Arts, John Street, Adelphi, W.C. The chair was taken by Colonel H. C. L. Holden, R.A., F.R.S., who is a member of the Council of the Society.

MOTOR BOATING.

A Club Launch.

IN connection with the Motor Yacht Club floating club house, a sea-going pinnace, by Messrs. Thornycroft, is to be regularly employed in maintaining constant communication with the shore. The launch will be mahogany built, 30 ft. in length, with 6 ft. beam, and will draw 2 ft. 10 in. of water. The engine will be a 4-cylinder, 4¼ by 5, 24–30-h.p., low-tension magneto ignition, and a cabin, 6 ft. 6 in., with a head room of 5 ft., will be fixed, having glass sides, so that passengers in wet weather will not be discomfited.

The Johore Cup.

A CUP, to be raced for during the coming season, has been presented to the Motor Yacht Club by the Sultan of Johore.

International Cup Race.

ENTRIES for this race—which will probably be held off Cowes during August—will close on July 1.

British Motor Boat Club.

THE new burgee of the British Motor Boat Club, which is quite different from any published in Lloyd's Yacht Register, is blue with a red St. Andrew's Cross (diagonal cross) with a white border.

The racing fixtures for this season will probably be, June 5th, Oulton Broad; June 8th and 9th, Liverpool; a date in July at Cowes, in Cowes Week in August, and at Burnham in early September.

* * * *

Armour-Clad Cars.

THE idea of armouring motor cars for military purposes, which was first, we believe, proposed in this country by the notorious E. J. Pennington in the early days of automobilism, and subsequently brought up again by Mr. F R. Simms, a description of whose machine appeared in THE AUTOMOTOR JOURNAL for the 19th April, 1902, would seem to be coming to the front again. Possibly it is the revolutionary state of affairs prevailing in Russia which has provoked this return to the militarisation of the automobile. At any rate, Messrs. Charron, Girardot, and Voigt, have just completed the first of a number of such vehicles for the Russian Government who have, doubtless, at present good cause to require their services, and another similar arrangement, constructed by the Opel-Darracq Company, was exhibited by that Company at the recent Berlin Automobile Exhibition. We, this week, reproduce a photograph of the C.G.V. machine, and draw attention to its leading characteristics in the title. The Opel-Darracq military automobile is an ordinary 4-cylinder touring car, developing 40 h.p., and is armour-plated, or, at any rate, provided with bullet-proof plates to reach above the heads of the occupants. These can be removed, and the car employed as an ordinary touring car if needed. Its total weight, when fully armoured and provided with its guns, amounts to 2,400 kilogs., in which condition it is said to be capable of developing a speed of 40 kiloms. per hour. The armament of the car consists of two Mauser quick-firers and two Mauser quick-firing pistols. The car is also equipped with a telescope on a stand.

Railway Motor Coach Privileges.

ONE is compelled to wonder what is happening to the Board of Trade in its hoary old age, unless it be a most spasmodic rejuvenation under its new head. For the six new rail motor cars which the Great Northern Railway have been adding to their stock are actually to be allowed to run on the rails and stop at intermediate spots where there are no stations. It will be a great convenience to the local population, no doubt, but the most encouraging feature of the situation is the extraordinary revolution of ideas at the Board of Trade, of which the granting of such a concession is evidence.

A Side-Slip Catastrophe.

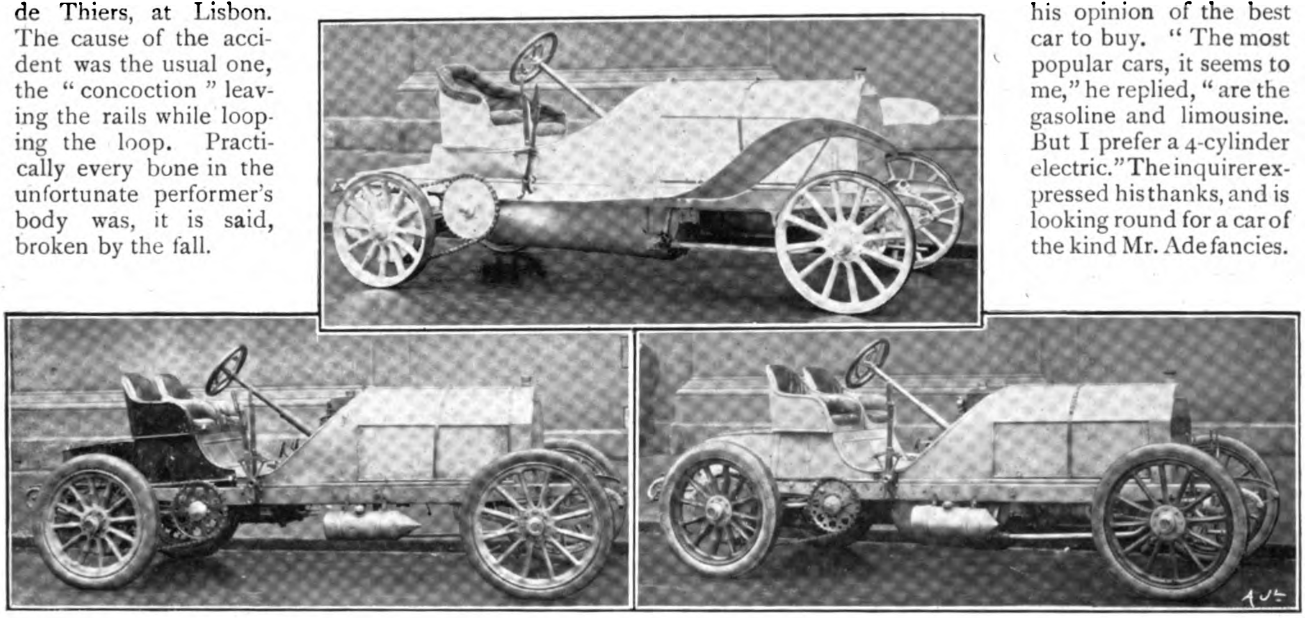
WHEN motor omnibuses were first put on the London streets, shod with solid rubber tyres, many people, realising their huge weight and the number of times they would have to be stopped, turned, and otherwise manœuvred on streets often so slippery that the London cab horse, in spite of his many years of practice, can only keep his footing upon them when encouraged by "strange oaths," predicted that motor 'buses would be slithering about the Metropolis like a herd of hippopotami on an ice skating rink. The prophets of evil have in this, as in so many other cases, been utterly out of it, and the motor omnibus has surprised its patrons quite as much by its absence of side-slippiness as by its high average speed, controllability, and perfect genius for picking its way through crowded traffic. One of the first, if not the first, motor 'bus side-slip accident, which has resulted in a coroner's inquest, is an occasion, therefore, of very particular interest, and so are both the coroner's remarks and the verdict of the jury. The victim of the accident on whom the coroner's jury "sat" came by his end through being knocked over by the 'bus, just as he was alighting from it. A van—in this case, as in so many, the *fons et origo mali*—pulled up sharp in front of the 'bus, as they not infrequently do. The 'bus driver, to prevent a collision, clapped on his brakes, and the 'bus in consequence skidded, throwing off a passenger who was standing on the steps, and who in consequence suffered injuries to which he succumbed. The coroner, in summing up the case, made the general statement that all vehicles were liable to side-slip, but the way in which the side-slip occurred in a motor omnibus was more serious than in a horse-drawn omnibus, and added some remarks about sufficient being known regarding the tendency to side-slip to make the responsibility of motor 'bus drivers a very serious one. "They were bound," he said, "to know that a skid might occur, and the consequences might be serious injury to human beings, though in this case it could not be maintained that there was anything like serious neglect." The jury returned a verdict of "accidental death." That horse-drawn vehicles do not enjoy the comparative immunity from skidding apparently claimed for them by the coroner, was, however, pretty well illustrated recently at Surbiton. The local fire-engine was summoned to the Assembly Rooms, and the brigade, with the horse-drawn "steamer," proceeded to the scene of the conflagration at the usual high speed. Suddenly the wheel of the vehicle skidded on a tramway line, and horses and vehicle dashed in consequence into a stone wall surrounding a garden. The front of the fire-engine was smashed and the poor horses were injured, one of the firemen also sustaining slight injuries. And the fire brigade was the victim of a false alarm all the time.

Provincial Exhibitions.

Local motor and bicycle shows have been opened simultaneously in the provinces this week, at Manchester, Liverpool, and Newcastle, at which most of the leading makes of cars which have already been seen at Olympia are again represented. The clashing of dates, however, precludes all having an equal chance in this respect. Both at Liverpool and Manchester, however, a strong contingent of makers of commercial vehicles is in evidence, and help to make a show which is particularly suited to the requirements of the respective districts.

A Useless Death.

Another victim of those scandalous accidents due to the popular love of sensationalism—looping the loop in a concoction misnamed a motor car—which has already claimed one victim—a useless tragedy on which we commented forcibly at the time—has caused the death of Mademoiselle Mauricia de Thiers, at Lisbon. The cause of the accident was the usual one, the "concoction" leaving the rails while looping the loop. Practically every bone in the unfortunate performer's body was, it is said, broken by the fall.



Three "generations." Mercedes developments in Racing Cars during the past three years. Our upper illustration shows the very latest 120-h.p. model which has just been received by Mr. J. E. Hutton from the Cannstatt works. Beneath are photographs of an 80-h.p. car, built in 1904, and one of the 90-h.p. racers of last season.

The Gentlemanly Chauffeur.

There ought to be an opening for the gentlemanly well-educated chauffeur, who should be able to talk agreeably on all subjects as well as drive your car, and when the weather is too bad to take the vehicle out, can act as secretary, shorthand writer and typist in the house. At any rate, there is one enterprising young man who is able to do all this sort of thing, and who, as the following advertisement shows, is anxious to obtain a situation :—

> WELL-EDUCATED, gentlemanly young man (24), of good appearance and address, desires engagement as confidential clerk and chauffeur, private; town or country; shorthand and type-writing; thoroughly experienced; any petrol car; all running repairs; genuine.

That such an "Admirable Crichton" as this should be in want of a job is nothing less than a tragedy on a small scale. He has apparently modelled himself on Mr. and Mrs. Williamson's "Lord Richard Barrymore" in "My Friend the Chauffeur," and having studied for the part for some time, now thinks that he is capable of making his *debut* in it.

Motor Car Licence Staff to be Increased.

Owing to the great increase in the work, five instead of two L.C.C. officials have been empowered to sign motor licences.

A Yankee Yarn.

Mr. George Ade, the American dramatist, is the more or less proud possessor of a little Oldsmobile runabout, which he dubbed The Rolling Peanut. His experiences as a motorist he has published in a short story under that title, which the makers of the car have reproduced in booklet form, and distributed by tens of thousands at every American motor show. One of his admirers, after reading the story, says the *Standard*, approached Mr. Ade for his opinion of the best car to buy. "The most popular cars, it seems to me," he replied, "are the gasoline and limousine. But I prefer a 4-cylinder electric." The inquirer expressed his thanks, and is looking round for a car of the kind Mr. Ade fancies.

Fox Shooting.

The First Annual Dinner of the Bradford Automobile Club, which came off at the Royal Hotel in that city last week, is likely to be memorable in the recollections of Yorkshire Justices. Mr. Mitchell, who was one of the leading members present, proposed the Automobile Club of Great Britain and Ireland, and in the course of an entertaining speech he told a story of a friend of his who, when being fined before a fox-hunting Bench of Magistrates, and asked if he had anything to say, replied, "Yes. It is quite evident you intend to stop our sport, and if you do that we intend to stop yours. Every time I am fined now I shall shoot a fox, and get level with you in that way." As the shooting of a fox in Yorkshire and most English counties is looked upon as a crime somewhat worse than manslaughter, if not as bad as murder, the feelings of the magistrates may be more easily imagined than described.

CORRESPONDENCE.

⁂ *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion, or containing queries.*

FOUR CYLINDERS AND SIX CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I greatly regret to find that Mr. Edge has endeavoured to convey, in various communications to the Press, the impression that I am backing down after having made a challenge against 6-cylinder cars. As regards the correspondence which has taken place, the whole of this is available in the public Press, and I leave judgment in the matter to any fair-minded person who cares to read it.

Mr. Edge is certainly the person whose name is at present most associated with 6-cylinder cars, this association being, if I judge aright, entirely of his own seeking.

The facts speak for themselves, however. Mr. Edge made so many claims for 6-cylinder cars that I issued a general challenge. This has been taken up—by Mr. Claude Johnson! I think further comment is needless.

Yours faithfully,
H. H. P. DEASY.

February 13th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—It is really surprising this correspondence on the number of cylinders, whether they shall be 4 or 6, and at the same time excluding 8. Providing that in naming the number of cylinders, only that number of pistons are indicated, and that each cylinder has not two pistons. A much larger question is whether two pistons working in the continuation of one cylinder in contrary directions to one another, and making one set of valves for two impulses on the crank, is, or is not, the correct principle to employ.

Dealing with the number of piston impulses given to the crank is child's play and unworthy of serious correspondence. It is simply this—which no one can contradict. The more the merrier! To argue against this would be to contend that a water-wheel would run smoother, and be more efficient by having four buckets in its circumference than one having 100 or 200.

The only objection to increasing the number of cylinders is to be found in increasing the number of working parts, *unless* a rhythm of impulse to be given to the crank-shaft, necessary to the smooth working and wearing of all parts, cannot be gained without this. Regarding in this light cylinders as being only the exteriors of the pistons in which they work.

But a better system has been established in part by the Gobron-Brillié and Arrol-Johnston cars, in which systems two pistons work in contrary directions, and so make the *possibilities* of reducing the number of valves and parts by half. Remember, I do not say they actually do so; but on this system, one impulse *can* be given to the crank on each revolution on the ordinary petrol engine, and the number of valves and their wearing parts reduced by half.

It is absolutely useless to prove to a point by using cars whether 4, 6, or 8 cylinders are correct, by allowing cars commonly sold by standard patterns to compete.

However, this is patent to us all, that the 8-cylinder Darracq is a victor in establishing world's records.

In concluding this letter, I would like to bring forward a fact with regard to cylinder construction, which has been absolutely proved correct by the performances of the 82 × 82 3½-h.p. Minerva motor cycle engine—which is this, viz., the greatest cubic capacity of gas can be got within the walls of a cylinder, and the minimum friction speed of the piston, by making the bore and stroke of equal dimensions. Here we find the greatest economic efficiency, provided that the number of revolutions of the engine will admit of the speed at which the gases can be burnt, shall not be above this, otherwise we find burning gases in a blue flame emitted from the exhaust ports.

Efficiency with economy is part of the Tourist Trophy Race, and this is part of its principle.

Yours faithfully,
Pangbourne, Feb. 12th. J. M. NAPIER.

FALSE RUMOURS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—It has come to our knowledge that certain ignorant and prejudiced persons are spreading false reports with reference to the Arrol-Johnston cars which ran in last year's Tourist Trophy Race, and gained first and fourth places. It is stated that in order to reduce weight they were fitted with paper bonnets, mudguards, &c., and that all extras were taken off with the same object; and, further, that the petrol tanks were placed in absurd positions with the object of gaining power, the position being an impossible one in an ordinary touring car.

We wish most emphatically to deny each of these statements. Our cars were built from parts of standard design throughout, with the exception of the frame and wheels, which differ from our standard practice in so far as they are made lighter to allow the chassis to come within the maximum limits as to sizes and weights imposed by the stringent rules laid down by the Automobile Club. As a matter of fact, the weight of the chassis was only a few pounds below the maximum imposed, so that it is apparent that no attempt was made to procure a light racing machine for the Tourist Trophy event only, but a machine was produced which has proved itself capable of the hardest work under ordinary touring conditions.

As to extras, the car of course ran with a complete set of lamps, spare parts, tools, tyres, horn, dashboard clock, air pump for petrol tank, and in fact, all accessories that are usual and necessary on motor cars.

With regard to the position of the petrol tank, this was fitted under the back seat in a usual position, and it was pressure-fed from the exhaust.

We, in common with other manufacturers, received before the race certain rules as to sizes and weights, and we were careful that the car was built in such a way as to comply with these rules in every respect, so that no alterations of any kind were either suggested or demanded by the Club officials before the race, and both cars therefore, raced exactly as they left the works.

The winning car has been, and will be exhibited, at Olympia, Edinburgh, Liverpool and the Glasgow Motor Shows, and is there seen exactly as it ran in the race, so that the public may satisfy themselves as to whether it is a standard vehicle or not.

It has been stated that our cars were very low—specially-built racing machines—and that consequently great speed could be obtained. This is not the case. The "Arrol-Johnston" chassis was higher from the ground than that of any other competing car with but two exceptions. The height of the backs of the seats were also higher than is this year fixed as a minimum. The fact of the case is that the car looked lower than is usual, this optical delusion being due to the fact that the car was fitted with a low and broad bonnet and had large tyres on the wire wheels, the tyres being "Continentals," 815 by 105 mm. on all wheels. We were able to fit a low bonnet on account of the centre of gravity of a horizontal engine being very much lower than in the case of a vertical engine, and we fail to see why we should fit a high bonnet—which affects the speed and petrol consumption of a car—merely because other people require to do this on account of the design of their engine. We are surely entitled to take all the benefits we possibly can derive from the use of a specially-designed and efficient engine such as ours is.

We trust that you will see your way to publish this somewhat lengthy letter, but the persistent manner in which the statements referred to are being circulated is annoying.

Yours truly,
For THE NEW ARROL-JOHNSTON CAR CO., LTD.,
John Napier, Managing Director.

Paisley, February 12th.

EXAMINATIONS FOR AUTOMOBILE CLUB CERTIFICATES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I desire to ask your kind assistance in making known, through your valuable medium, that owing to the already large number of entrants the examination for the above certificates, already announced to be held in London, on Wednesday, February 21st, will be continued on the following day.

It is necessary that all who desire to attend these examinations should send their application forms so as to reach me not later than the first post on Monday, February 19th.

I am, yours faithfully,
J. W. ORDE,
February 12th. Secretary.

FUEL CONSUMPTION.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Interested partisans of 4-cylinder motors have made statements in the public Press that a 6-cylinder car was wasteful of petrol. Knowing this to be untrue I had an official petrol consumption test carried out on the same 6-cylinder Napier which recently ran under the Automobile Club's observation from Brighton to Edinburgh on top speed.

The result of this petrol consumption test is an overwhelming demonstration as to the extraordinary economy of the 6-cylinder engine, as you will see from the copy of the official certificate which I enclose.

The run took place on February 8th from Barnet to Grantham and back—200 miles—and the consumption worked out at 18·78 miles per gallon.

The certificate points out that the roads were very stony in places, for the greater part of the distance were wet and greasy, and that the temperature was low, being as low as 31 degs. Fahr. at the finish of the run and 36 degs. Fahr. at the start, so that what the standard 4 in. by 4 in. 6-cylinder Napier would do in fine summer weather with dry roads, would, I think be at least 10 per cent. to 20 per cent. better than even this magnificent performance.

It is pleasing to think that not only has Mr. Napier led the world with his 6 cylinder principle, but also he has been right from the first that the petrol consumption is extraordinarily small for 6 cylinders, having such a large total capacity as the officially certificated engine in question, which disproves once and for all the sole remaining argument against 6 cylinders.—Yours truly,

Feb. 10. S. F. EDGE.

Automobile Club Certificate of Performance.

Supplementary to the certificate issued in connection with the run on highest gear from London to Edinburgh on October 10th, 11th, and 12th, 1905.

The object of the run made on February 8th, 1906, under the official observation of the A.C.G.B.I. was to ascertain the petrol consumption per mile of the same 30-h.p. 6-cylinder Napier car which ran from London to Edinburgh.

The car was the same in all respects, with the exception that 16-tooth sprockets were fitted on the countershaft instead of 12-tooth. The weight of the car and four passengers on February 8th, 1906, was 4,227 lbs.

The run commenced at the twelfth milestone from London on the Great North Road, which was followed through Grantham for 100 miles, and thence back to the twelfth milestone, where the petrol consumption was ascertained by the *club's* Observer.

The total amount of petrol used was 10 gals. 2 qts. 1 pt. 4 ozs., which is equivalent to 18·78 miles per gallon.

The roads were very stony in places, and for the greater part of the distance were wet and greasy, this being especially noticeable on the return journey. The wind was strong, and varied from about S.W. to N.W.

The temperature was low, as the following observations taken on the road show :—

7.13 a.m. (start) ...	36° F.	1.48 p.m. ...	41° F.
9.0 a.m.	40° F.	3.27 p.m. ...	38° F.
11.30 a.m.	47° F.	6.13 p.m. ...	31° F. (end)

Tyre troubles were experienced on four occasions during the run, which caused considerable delay.

There were no mechanical troubles of any kind.

THE FLYING PROBLEM.

To the Editor of THE AUTOMOTOR JOURNAL.

Sir, —I should like to hear if Mr. Roe's model, illustrated to-day, is to scale, or only a toy ; according to the teaching of S. P. Langley, the Brothers Wright, Sir H. Maxim, and others, the results from small models are so illusive as to be practically of no use.

If a scale model, according to the data of the Wrights' 1900, '01, '02, '03, '05 full-sized machines, it does not resemble, only in one or two points.

Again, if built full size, from the same proportions, it would lose one of the Wrights' distinctive features, namely, reduction of friction.

They, by careful design of framework, &c., were able to reduce the body resistance to 50 per cent. of what had ever been done before.

Until recently I was always under the impression, if you were attempting to build or experiment with any little-known subject, the usual thing was to read up all the available data relating to the object. It almost seems that this is not followed by most aeronautical experimenters. Witness the Hamilton plane; it can be shown that a plane of the dimensions given, about 22 ft. wide, 16 ft. long, by 6 ft. between the planes, total effective area about 425 sq. ft., with planes not properly supported (as the shape would alter very much when carrying a weight), would require 50 per cent. more power to propel than a Wright machine of similar size.

Such problems as equilibrium seem of minor importance.

Then, again, we have in to-day's *English Mechanic* Mr. E. Wilson's machine, which is said to be nearly ready for trial.

It appears to be a combination of an aerial screw machine and aerocurve. He proposes to uplift a machine 40 ft. long with transverse aerocurves, rudder, four 7 ft. diameter aerial screws, two 5 ft. diameter propelling screws, and a Blake 12-h.p. motor, aeronaut, &c., total weight 300 lbs. The motor 70 lbs., aeronaut 130 lbs. = 100 lbs. for framework, gear, screws, &c.

Now, the Wright Brothers found it necessary for safety, even in their gliding machines, to have not less than 100 lbs. weight of material. Also, according to available data, the thrust to be obtained from four small 7 ft. diameter screws, 12 h.p. would not be enough by fully 50 per cent. Of course, equilibrium is again very easily obtained.

Yours,

Acton, February 9th. MICA CAM.

AN EXPERT'S OPINION ON 6-CYLINDER MOTORS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—The opinion of very few expert automobile designers is held to be of such weight as that of Herr Maybach, to whose designing and continuous care so much of the success of the Mercedes car is due. It is interesting, therefore, to all automobilists to note Herr Maybach's opinions on the question of the use of 6 cylinders which appeared in the *Allgemeine Automobil Zeitung*, in which he states that "one cylinder would be best, two are still acceptable, four are too many, and as for six —!" We may therefore take it that he considers any number over two cylinders too many. Personally I must say that in driving either a 4 or 6-cylinder motor I have not found two extra cylinders either complicated or a drawback, as compared with those of two or four cylinders respectively. He continues, "but if you have ever ridden on a 4-cylinder car then you would not return for anything in the world to a 2-cylinder." And the 6-cylinder enthusiasts believe it to be the same with their new construction. In one thing I cannot but think them right, for "the 6-cylinder motor must possess a wonderful variability of pace." As everyone who owns a correctly-designed 6-cylinder car express themselves in just those words, viz., "that they would not return for anything in the world to a four," Herr Maybach has evidently made an accurate camparison.

After pointing out that the 6-cylinder motor, which he describes as a complication designed with the idea of "driving out the devil with Beelzebub," as it is constructed to run at all speeds on a high gear, and so do away with the necessity of changing speed-gears—which he owns are unmechanical—he goes on to point out that he hopes to bring out a slipping-clutch which will enable a 4-cylinder car to be driven slowly on a high gear.

It appears to me that the necessary complications of a slipping-clutch, and a greater number of gear wheels, which he finds to be the only manner of attempting to bring even a high-class 4-cylinder motor on a par with a 6-cylinder motor, may with even more truth be described as "casting out the devil with Beelzebub" in the attempt to make four cylinders as successful as six.

But Herr Maybach evidently recognises that there are advantages in the use of six cylinders, which seems to me to particularly apply to the ordinary use of a car by an ordinary driver—especially in traffic—for he points out how the use of six cylinders makes a car easier to drive, as he says, "I can only recognise the justification of the 6-cylinder motor in one case. When the driver wants to get along quickly, when he has to keep his hands on the wheel, when he has not time to change gears, or when a wrong manœuvre with the speed-lever might mean costly seconds, then the six cylinders, where the play with the throttle and advanced ignition permits of every speed variation, is fully justified."

It is interesting to hear these opinions in view of the fact that Herr Maybach is now experimenting with a 6-cylinder Mercedes.

I venture to think that even Herr Maybach will agree with me that, taking an engine of a given horse-power, one with six cylinders compared with one of four or less, shows the following advantages for six cylinders : quietness, less shock on all mechanism, less wear and tear on tyres, easier to start, more flexibility, does away with nearly all changing of speeds.

Yours truly,

Feb. 9th. S. F. EDGE.

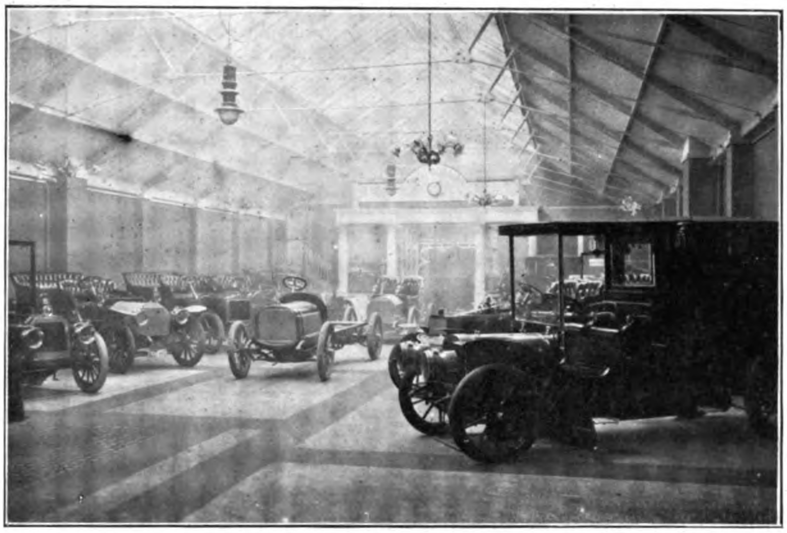
BRITISH *v.* FOREIGN CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In connection with the disinterested offer made by Mr. S. F. Edge, to inspect and test in a practical way the construction and performance of his 6-cylinder Napier car, we, having recently availed ourselves of his patriotic offer, are desirous of publicly thanking Mr. Edge, and to state that in our opinion the 6-cylinder car is undoubtedly a great improvement on even 4-cylinder cars. The smoothness of running, and the range of control on top speed, are everything that can be desired, and we have much pleasure in testifying to our satisfaction on all these points.

We are, yours truly,
THE VAUXHALL AND WEST HYDRAULIC ENGINEERING
COMPANY, LIMITED.

Feb. 10th.



"Automobilia," the Motorists' new Emporium in Oxford Street.—A view of the main Garage.

Automobilia—the Motorists' New Emporium.

MOST motorists who are familiar with London know the well-situated premises in Oxford Street, near the Marble Arch, which have since its first connection with motoring been known as Automobilia. A change has come over the place recently, however, and an entirely new management has taken possession—Mr. Easton, who is so largely responsible for the popularity of "The Motor House" being among those concerned in this new departure. It is intended that the premises shall be a "William Whiteley's" in the motor world, and provision is being made for supplying everything that a motorist can need, from the car itself to the chauffeur's livery, and the smallest accessory requirement. Very capacious show-rooms have been opened on the ground floor, where clients may inspect at leisure numerous up-to-date models of modern cars. A special department for hiring out cars has been formed, and the motor clothing and accessory sections are also very complete.

What is a "Show Chassis"?

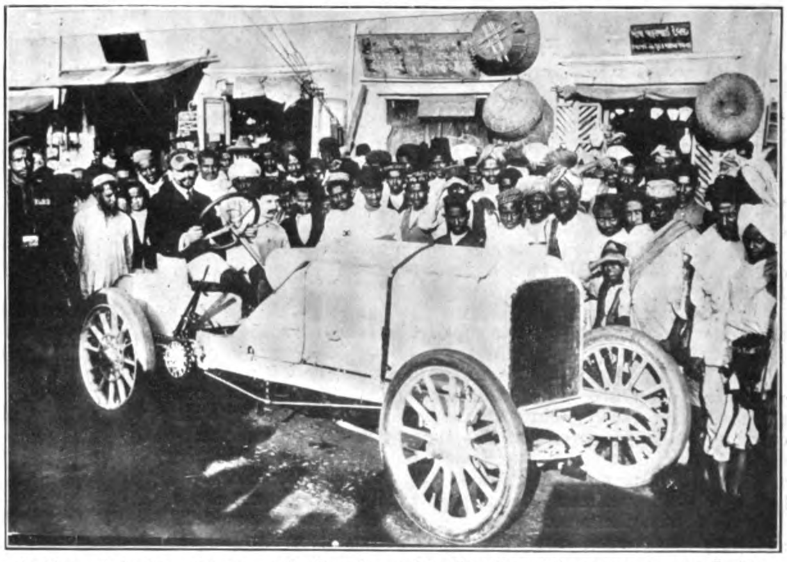
GAULOIS TYRES, LIMITED, have been offering through our advertising columns a prize of a £10 note for the best definition of "What is a Show Chassis"? and we understand great difficulty has been experienced in making the award. Some of the readers have treated it as a conundrum and answered accordingly. Others thought it an occasion for flippant remarks. One gentleman from Bristol said that everybody knew what it was, "except the man who said, 'a chassis was a female chauffeur.'" *He* described it as follows:—"A show chassis is a chassis a replica of which the exhibitor hopes he can kid the public they are going to buy; which the novice believes he is going to buy." Another was a laconic reply:—"It is like beauty, 'only skin deep.'" Some of the replies were technical and descriptive, but at the same time particularly inappropriate, one man sending an absolute essay on what a show chassis is, should be, and should avoid. One sender burst into poetry and contributed a whole stanza. But one thing is certainly made patent by this sort of competition, and that is the very great variety of readers who watch the advertisements, as the senders of answers appear to embrace nearly every class in Society.

Blackpool Retrogressive.

IT was announced some months ago by THE AUTOMOTOR JOURNAL that the Blackpool Corporation had decided not to permit any more motor meets upon the marine promenade. The town is evidently badly bitten by autophobia, as last week the Town Council approved the recommendation of the Watch Committee to refuse an application to introduce a motor omnibus service into the town during the summer season.

Influence of the Automobile on the Railway.

THE automobile is already making its influence felt on the receipts of some of the principal railway companies. Thus it is estimated that of the 1,200 to 1,500 additional first-class passengers from Paddington to Henley who have usually patronised the Great Western Railway, nearly the whole of this number journeyed to the regatta town by automobile last summer. Even at this time of year large numbers travel distances of from 100 to 200 miles; all that the railway companies get out of it being, as one official said, the conveyance of luggage in advance. The receipts of the Great Western Railway Company, when the Court is in residence at Windsor, are now said to show a distinct diminution owing to the same cause.



A Sea of Indian Faces.—M. Sorel, on his De Dietrich racing car in India, has created widespread interest, the natives particularly exhibiting their curiosity. M. Sorel is taking part in race meetings in India, and hopes thereby to further popularise the sport. M. Sorel was one of the trio who tied, as we recently reported, for the Bombay-Mahableshwar Trials. He was also the driver of the De Dietrich car which secured the Coupe de Pyrenees. This work of art came, it will be remembered, to a tragic end at Olympia, in connection with which incident, the sequel is recorded by us this week in the conviction of the thieves who annexed the Trophy.

COMPANY DOINGS.

Motor Omnibuses and the Old 'Bus Companies.

In a measure, the remarks of Mr. Henry Clinch, the chairman of the Associated Omnibus Company, Ltd., and the discussion which followed, at the meeting of the shareholders, on Monday last, were very satisfactory and formed a tribute to the remarkable revolution which mechanical traction is bringing about in the methods of the 'bus companies. Mr. Clinch stated that the introduction of motor omnibuses into their service had given satisfactory results. Motor omnibuses had, he said, rapidly increased, and there were at the present time no less than 260 working on the London streets. There was every prospect of this number being increased very largely during the current year. Motor omnibus companies were springing up like mushrooms in a night; whether some of these would as rapidly disappear remained to be proved. In any case, their company intended to keep abreast with the times in conjunction with the older companies, but they would still move with caution. It was just possible the present motor omnibus might be antiquated in two years' time, so quickly does machinery change and improve, but they were compelled by circumstances to advance quicker than they otherwise should. The "life" of a motor omnibus was still uncertain, but they were providing for depreciation at the rate of 25 per cent. per annum.

London Road Car Testimony to the Motor 'Bus.

We referred last week to the company's report for the past year. The accounts appear to be disappointing, but the figures relating to the motor 'bus are instructive. It states that there has been a considerable reduction in the weekly average receipts of the horse-drawn cars, due to the weather and to the competition of the new motor companies. The cost of foraging the stud of horses shows a decided increase. The cost of feeding per horse per week has been 9s., an increase of 9½d. The cost of bedding per horse per week has been 5d., and of shoeing 7¾d. Motor fuel appears, for the first time, in the accounts at £3,033. The "substitution suspense account" amounts to £17,125, and represents the loss in the substitution of motor for horse cars. The company have 53 motors in work, and there appear to be, in addition, 34 cars and 6 chassis in various stages of completion. In the circular to shareholders of the company, dated 2nd January, 1905, the directors stated "that the substitution of mechanical power for horse traction would be carried out gradually, the existing horses and cars being disposed of by degrees." Owing, however, to the rapid development in motor services by the advent of new competitive companies, it has been found absolutely necessary, in the interests of the company, to considerably accelerate the process of substitution, which will involve the sale of horses far in excess of the number which, in the ordinary course, have been disposed of in each half-year. The directors have accordingly decided to form the substitution suspense account referred to above, and to transfer thereto the value of the horses sold and not replaced, together with the value of the horse cars and harness not required, and this account it is proposed to extinguish by contributions from profits as opportunity affords. Further portions of the company's stables have been, and are being, converted into motor depôts and workshops for motors.

NEW COMPANIES REGISTERED.

"Bettoruss" Non-Skid Tyres (1906) (Limited), Craven House, Kingsway, W.C.—Capital, £1,000 in £1 shares. First directors, A. Duckham (chairman), Mrs. Violet E. Duckham and P. N. Hooper.

C. Fonteyn (Limited) (87,497)—Capital, £2,000 in £1 shares. Object, to deal in motor vehicles of all kinds.

Edinburgh and District Motor Omnibus Company (Limited), 236-9, Finsbury Pavement, E.C.—Capital, £200,000, in £1 shares. Objects, to acquire from the Motor Car Emporium, Limited, certain contracts, motor omnibus chassis, &c. Directors, W. Roberts, Sir Robert Dashwood, Bart., J. Wilson, J.P., and N. D. Macdonald.

Electrocars (Limited), Alderman's House, Alderman's Walk, Bishopsgate Street, E.C.—Capital, £8,000 in £1 shares. Object, to acquire inventions for improvements in electrically-propelled vehicles. First directors, W. N. Stewart, A. R. Baird, and B. W. Parker.

New Leader Motors (Limited), Aspley, Nottingham.—Capital, £15,000 in £1 shares. Object, to acquire the business carried on by Leader Motors, Limited, at Nottingham and elsewhere.

NEW ISSUES.

Deasy Motor Car Manufacturing Company (Limited).—Under the above title a prospectus will be shortly issued. The object of the company is mainly to manufacture in England motor cars, omnibuses and delivery vans, and to acquire the business hitherto carried on by H. H. P. Deasy and Co., Limited, of Brompton Road. We recently announced the intention of Captain Deasy to manufacture a new British car, and the new formation is the result of the work now in progress. Captain Deasy's experience and sound judgment promise well for the new venture, especially when taken in conjunction with the co-operation, as engineer and works manager, of Mr. E. W. Lewis—who has been successfully associated in the past both with the Daimler Company and the Rover Company. Moreover, practical business men will be found as directors of the new company in addition to Captain Deasy, the board comprising Sir Richard W. Griffiths, Bart., Sir Robert W. Buchanan-Jardine, Bart., a director of the Caledonian Railway Company; Mr. E. J. Brook, a director of the Glasgow and South-Western Railway Company; and Mr. K. H. Buchanan, who has been associated with H. H. P. Deasy and Co., Limited, and the London Power Omnibus Company, Limited, and is also a director of the Welsbach Incandescent Gas Company, Limited. A strong feature of the company is that practically the whole of the purchase price is payable in shares, leaving the cash subscribed available for working capital, purchase of land, &c.

A repair department is to be established on a large scale. As already the design of the Deasy car is in an advanced stage, it is hoped that deliveries will be able to be commenced next summer. The capacity of the company's factory will be 250 cars per annum, and it is estimated a net profit of £16,000 per annum can easily be earned upon an output of 200 cars per annum.

The capital of the company is £150,000 in £1 shares, of which £100,000 constitutes the present issue, 18,746 shares are to be issued in part payment for the business of H. H. P. Deasy and Co., Ltd., and 31,254 shares are to be reserved for future issue.

The offices of the company are at 5, Copthall Buildings, E.C.

The Edinburgh and District Motor Omnibus Company (Limited) announces the issue of 190,000 £1 shares at par. The company has been formed to carry on the business of a motor omnibus company, and to establish a service in Edinburgh, Leith, and surrounding districts. The capital consists of £200,000, divided into £1 shares. The preliminary expenses (exclusive of brokerage) are estimated at £6,500, and will be paid by Mr. James Spencer Orr, of Finsbury Pavement House, E.C., who is promoter of the company. He has stipulated that he is to be paid £10,000 in cash, and have allotted to him or his nominees 10,000 fully-paid shares. 150 omnibus chassis are to be acquired from the Motor Car Emporium, Limited, the body portion to be supplied by Messrs. J. Liversidge and Son, Limited.

Wishing you the compliments of the season
24/12/05

After 18 months work, during which time repairs to car have not cost me 20/-. James Harding
Knypersley, Nr Congleton.

Owners of cars have various methods of expressing their pleasure with any particular form of motor car which they may have acquired. The above is an agreeable form of this character, and was sent by Mr. Harding to the Wolseley Motor Car Company, after having used his car for about eighteen months.

COMMERCIAL POINTS.

CLEMENT cars will be shown at the Manchester Exhibition by Messrs. Newton, Bennett and Carlisle, Limited, from February 23rd to March 9th. They will be shown at the Glasgow Show (March 9th–17th) by Messrs. Seligmann, of Renfrew Street, Glasgow.

UNITED MOTOR INDUSTRIES, LIMITED, have just received a communication from Mr. C. J. Glidden, in India, to the effect that the "Castle" accumulators which he has been using all through his Indian journey, have given him perfect satisfaction. The company are naturally gratified at Mr. Glidden's appreciation in view of the climate of India being generally considered to be very trying for electrical accumulators.

A Useful Desk Companion Free for the Asking.

RECENTLY we mentioned that the Shrewsbury and Challiner Tyre Company, of Ardwick Green, Manchester, were sending gratis a folding desk blotter to any of our readers applying to them. The company now write us in regard to this as follows :—

"The result has been an enormous number of applications for the same from all parts of the country, in response to which we have sent a blotter to every applicant.

"We have still a considerable number left, which we shall be glad to circulate amongst those motor car owners who have not yet availed themselves of the opportunity to secure one."

An Illustrated Export Catalogue.

"NEGOTIATORS, LTD.," of 34, Clement's Lane, E.C., are preparing a catalogue of motor vehicles and accessories for circulation amongst users and buyers in the Colonies and non-manufacturing countries. It is to be placed before the chief British Consuls abroad, Chambers of Commerce, and leading Corporations, business houses, and other likely buyers. A work of this character should prove useful for reference in many parts of the world where regular current literature upon most subjects is scarce.

LEGAL INTELLIGENCE.

The Alleged "Motor School" Frauds.

FURTHER evidence was given at Westminster last week in the charges of fraud against Riski Medawar, 22, an Armenian, and John Raymond Kerr, 21, respectively the proprietor and secretary of the Motor Drivers' Union, in connection with a motor-driving school, instruction classes, &c. Accused were again remanded.

The Theft of the Pyrenees Trophy.

FREDERICK HALL, alias Prince, twenty-three, bookmaker, of Wilmington Square, E.C., and Robert Henry Burn, nineteen, a jeweller's assistant, of Waterloo Terrace, Islington, were convicted at Clerkenwell Sessions, last week, of having stolen the silver trophy, known as the Coupe des Pyrenees, weighing 900 ozs., and valued at £1,000, from the stand of Messrs. Charles Jarrott and Letts, Ltd., at the Motor Exhibition at Olympia, on November 27th.

In cross-examining Mr. Charles Jarrott, Mr. Symmons (who defended Hall) asked whether the photographic illustration of the female figure in the trophy on the police reward bills was symbolical of the ordinary chauffeur. "I hope not," said Mr. Jarrott, with a smile. "I hope so, too," commented Mr. Symmons, "because the lady is looking one way and driving another."

Hall was sentenced to three and a half years' penal servitude and two years' police supervision, and Burn to twelve months' hard labour.

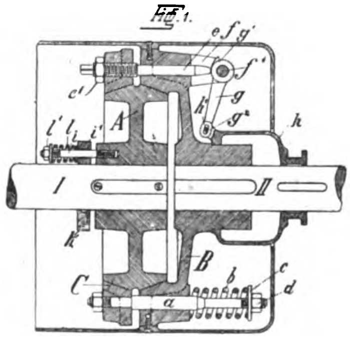
BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application ; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

20509. 10th October, 1905. Improvements in Double Cone Friction Clutches or Couplings. Hugo Baumgärtner-Mica, Mittlerestrasse 80, Basel, Switzerland. Date under International Convention, 10th October, 1904. This invention refers to a double-cone friction-clutch or coupling, having a solid double-cone axially movable upon one rotating part, whilst the other rotating part is provided with a coupling-pulley formed as a hollow cone adapted to fit or engage one half of the double-cone. A pressure-ring adapted to fit the other half of the solid double-cone is movable axially by means of bolts fixed in same, and connected by means of helical spring discs and nuts with the coupling-pulley. There are two figures. Fig. 1 is a central longitudinal section. A is the solid double-cone axially movable upon the shaft, I. B is the coupling-pulley keyed upon the shaft, II, and C is the pressure-ring axially movable, and connected with pulley, B, by the bolts, *a*. On the latter are placed the springs, *b*, which tend to engage the pressure-ring, C, with the double-cone, A, and thus to put the coupling in gear, and the tensioning thereof is effected by the washers, *c* and *d*. The disengaging or releasing-bolts, *e*, are screwed into the ring, C, and held fast in position by the guard-nuts, e^1. The bolts pass through holes in the coupling-pulley, B, so as to extend to the other side with a terminal part. Bolts, f^1, are located in lugs on the pulley, B. for the purpose of receiving the oscillating levers, *g*, provided with a cam, g^1. *h* is a disconnecting-sleeve, provided with pins, h^1, which latter are passed through slots, g^2, in the lower ends of the oscillating levers, *g*. In the rear part of the hub of the solid double-cone, A, are secured two studs, *i*, which pass through holes, i^1, in a ring, *k*, adjustably secured upon the shaft, I, and are provided with springs, *l*, which later can be regulated in tension by means of the nuts, l^1, so that when the coupling is out of gear the double-cone, A, is drawn back until it reaches the ring, *k*. The coupling is put out of gear by an axial outward displacement of the sleeve, *h*, whereby the cams, g^1, of the disengaging levers, *g*, push the bolts, *e*, backwards, so as to disengage the pressure-ring, C, from the double-cone, A.—January 24th, 1906.

Fig. 1.



23557. 16th November, 1905. Improvements in Internal Combustion Engines. Frederick H. Royce, Cooke Street, Hulme, Manchester. The subject of this invention is an improved arrangement of engine and of mechanism for the driving of the water and oil pumps. There are two figures. Fig. 1 is an end elevation. The cylinders, A A, are bolted to the crank case, B, in two rows radially to the crank shaft, Q, each set being inclined at 45 deg. to the vertical. The inlet and exhaust valve chambers, C, in the cylinders, A A, are arranged, so that the inlet and exhaust valves, D, work vertically. The valves, D, are operated by small tappet levers, E, which are themselves worked by cam shafts, F F. The cam shafts, F F, are driven from the crank shaft, Q, by means of gear wheels, R S T. The crank shaft, Q, and the cam shafts, F F, of which there are two, have their bearings complete in the top half of the crank case, B, so that the bottom half of the crank case, G, may be removed without disturbing the mechanism. Forced lubrication is provided for the crank shaft and cam shaft bearings. The crank pin brasses are lubricated by oil forced through holes drilled in the crank shaft. The supply is taken from the oil under pressure at the main bearings The pressure in the oil system is maintained by the pump, H. The two pumps, H J, for the circulation of oil and water respectively (which are of the gear-wheel type) are fixed to the bottom half of the crank case, G. A vertical shaft is driven from an intermediate wheel, S, by means of a pair of bevel wheels. The two shafts parallel to, and driven by this shaft through gear wheels form the drive for the two pumps.—January 24th, 1906.

PASSING EVENTS.

A Determined Onslaught on Dust.

We are glad to be able to announce the imminence of what we trust will prove to be the most determined and instructive onslaught upon the dust-fiend which we have yet seen. A joint committee of the Roads Improvement Association and the Automobile Mutual Protection Association are arranging to subject portions of the Maidstone Road between Wrotham and Maidstone to treatment with various anti-dust road-making materials. No mere palliatives are to be employed, but lengths of 500 yards of the road are to be made up as if the road were being mended in the ordinary fashion with representative materials which, there is reason to believe, really make a road in which the formation of dust, if not an impossibility, is reduced to a minimum. Three types of materials are to be experimented with. These are:—

1. "Tar-Mac," a preparation to which we have frequently alluded in previous numbers of the Journal. The Tar-Mac to be employed on the Maidstone Road is to consist of blast furnace slag, broken to the size of ordinary rather small road metal, and impregnated with tar when hot. The blast furnace slag is of very special degree of hardness, being that obtained from blast furnaces when producing very grey pig-iron such as is employed for making steel in the Bessemer converter.

2. "Quarrite." This is a patented preparation in which crushed limestone replaces the blast furnace slag in the Tar-Mac, being similarly treated with tar when hot. It is understood that a special point in employing this material is the selection of proper proportions of various-sized material.

3. "Kleinpflaster." This is a method of road treatment to which we referred recently, and consists in facing the ordinary surface of the road when well and carefully made up, with small rectangular blocks of granite cut out by a special machine. The sets are said to wear smooth and produce a good surface in course of time.

The Tar-Mac, as our readers know, has already been tried with good results in London, Nottingham, and elsewhere; the Quarrite was used, and is said to have given satisfaction, on the Blackpool Promenade, and the Kleinpflaster is employed, it is alleged, with success in various parts of Germany. Of course, the Joint Committee may be relied upon to give fair treatment to the three competing preparations. It would, obviously, not be a fair test to put 500 yards of one material where the road goes through a damp and shady valley, and 500 yards of another on an exposed sunny hillside like Wrotham Hill. We think, too, that it would certainly be wise not to lay the specially-prepared stretches quite close together, for it would be a pity if anything were allowed to favour one type of material more than another. It would at any rate reduce this risk if short lengths of ordinary road were left between them. The great object of the experiment is to provide data on which local authorities responsible for highway maintenance will feel they can fully rely. The Maidstone Road is one of the roads out of London on which traffic is most severe, owing, amongst other things, to the large amount of agricultural produce brought up by wagons, lurries, and traction engines, to the markets of the Metropolis, and, in fact, the general opinion seems to prevail, with much justice, that road material that will stand on this road will stand anywhere, while if it will not get dusty in the neighbourhood of Maidstone, it will have proved its capacity for vanquishing the dust fiend on any highway in the British Islands. We sincerely trust that the experiments will be satisfactory. The chief obstacle to the adoption by local authorities of Tar-Mac and other permanent cures for dust is the initial expense. If, however, it can be proved that this greater initial cost is, as we believe is the case, more than counterbalanced by a subsequent economy, and that instead of spending more of the ratepayers' money to secure dustlessness they will in the end be economising it, we think that great desideratum of every member of the community (at any rate, of all who live along the sides of roads in the country or in country villages)—the dustless road—will become a reality before very long.

◆ ◆ ◆

To Stop 'Bus Racing.

The Vanguard omnibuses, the first effective line of motor 'buses on the London streets, had not been long catering for the traffic of the Metropolis, when a rival service was started in more or less direct opposition to them. We entertained at the time—and expressed—a good deal of dread that we should see a repetition, on motor 'bus lines, of the dangerous farce which, when enacted by horsed omnibuses a good many years ago, made London streets both a danger and a laughing-stock to their users, and the subject of mockery in Continental papers. We refer, of course, to the tactics adopted by the more powerful companies of what is politely termed "running their rivals off the road." The method employed was barbaric in its simplicity. Two 'buses of the stronger company were told off to "nurse" each of the 'buses of the new company which was selected as a victim. One of these made it its business to arrive at every important corner first so as to pick up the waiting passengers, the other followed closely behind so as to pick up any that happened to be left. In this way the receipts of the new competitor were effectively diminished, partly because the other 'buses picked up the people who would otherwise naturally have become its passengers, and partly because all who were not gifted with a strong sporting instinct and nerves of steel were disinclined to adventure their necks in these encounters which, though often humorous, were frequently waged with almost gladiatorial ferocity. As to arrive at a given point first on all occasions was an essential element in the game, racing resulted, and drivers and conductors joined in it with absolute delight. We have already pointed out, as above mentioned, that dangerous and bad as this sort of thing was with a horsed omnibus, it would be far more dangerous both to passengers and other users of the streets if adopted by motor 'buses.

◆ ◆ ◆

The Recrudescence of an old Evil.

So far things have gone along fairly smoothly, but already symptoms of the old evil in an exaggerated motor 'bus form, are becoming apparent, as travellers in the Metropolis must have already noticed, and complaints are beginning to appear on the subject in the daily Press. The competing 'bus companies, or their managers, naturally enough, disclaim all responsibility, insinuate that the trouble is due to the natural sporting instincts of rival drivers, and explain that their yards are fairly plastered with notices announcing all kinds of awful penalties against drivers who ever give way to temptation, and indulge in "point to point" steeplechases of the kind referred to. They used to say much the same thing in the old days of horsed 'bus racing, although even then their denial met with almost universal scepticism. At any rate it was not the drivers or conductors who arranged for two 'buses to accompany a single 'bus belonging to the rival company. Possibly they were told not to race, as a certain assembly was once advised not to nail a certain ear to a certain pump, and the present disavowals of the present companies are no doubt just as sincere as the former ones. But in any case it is a very remarkable coincidence that on one particular line at any rate, one motor 'bus belonging to one company is almost invariably seen with two motor 'buses belonging to another company in close attendance (in front and behind) upon it, while this apparition is followed by a 'busless interval varying very often from ten minutes to a quarter of an hour.

◆ ◆ ◆

Must be Stopped with a Ruthless Hand.

We say again, that any attempts to introduce among motor 'buses this preposterous misuse of the streets should be repressed at once by the police with a firm hand. They had difficulties in the old days with the horsed 'buses, for they could do nothing but summon drivers and conductors, the penalties imposed were trifling, and were probably not really paid by the drivers and conductors actually fined. The police will have to adopt some more drastic method in the present case, for the danger is a serious one, while the injury that will result to the development of the motor 'bus and the impediments that will be placed in the way of the gradual motorization of our street traffic will be incalculable. We presume the police possess adequate powers. If their powers are found not to be adequate, they should be intensified by legislation at the earliest possible moment. Dangerous nonsense of this kind *must be stopped!*

◆ ◆ ◆

Using the Engine as a Brake.

Very considerable thanks are due to Dr. Watson for the valuable paper which he read before the Automobile Club, last week, on the subject of employing the engine on an ordinary petrol car instead of an ordinary brake, for retarding the vehicle. In this paper, which we reproduce on another page, he has handled the question with a degree of thoroughness and a degree of suggestiveness which has never before been accorded to it, and if any confirmation of this statement were needed, it is provided by the remarks of Mr. Dugald Clerk, who, in opening the discussion, pointed out that the high degree of accuracy which Dr. Watson had succeeded in obtaining, had enabled us to learn what we had never before known with so great an approach to exactness—the real efficiency of the small petrol engine—a valuable result due to Dr. Watson's exceptionally skilful manipulation of the manograph.

◆ ◆ ◆

What the Braking Effect can amount to.

The most interesting features of Dr. Watson's paper are those in which he contrasts the braking power of an ordinary petrol engine with what it might become with a slight alteration in the valve mechanism, and the definite figures which he gives in each instance. Thus we learn that with an ordinary engine the maximum braking effect is some 33 per cent. of the power of the engine, yet by the introduction of special mechanism for causing the pistons to compress air during each backward stroke, and to then allow the air to escape to atmosphere, as much as 65 per cent. of the engine power can be obtained for braking purposes. On a car, however, it might actually be made even greater than 65 per cent., because the transmission losses should be added to the brake effect, whereas they have to be deducted from the engine power. Taking these losses as being 15 per cent, Dr. Watson estimated the maximum braking effect at 88 per cent. of the maximum engine power.

◆ ◆ ◆

How Far it is Wise to Apply it in Practice.

Dr. Watson did not express any personal opinion as to whether it was wise so to use an engine on a car or not. In the discussion that followed, however, the general view was apparently all in favour of adopting such a course, and none of the speakers alluded to the decided disadvantages that exist, on mechanical grounds. Now it seems to us that the transmission losses on a car represent useless strains and stresses in the driving mechanism, strains and stresses, in fact, which are tending to disintegrate it, and ultimately reduce its strength. The moving parts, moreover, are usually subjected to strains in one direction only, whereas if the engine is used as a powerful brake the direction of strain would be constantly alternated, and the various shafts, bearings, and gear-wheels would receive a most injurious racking motion. Further than this, the heavy fly-wheel on the high-speed engine-shaft tends to prevent sudden variations of speed at that end of the mechanism, and consequently abnormally severe shearing and twisting strains—far in excess of those which the engine normally exercises—may be imposed on the transmission mechanism by using the engine as a brake. In the case of ordinary touring cars, it is quite possible that this may not be found to do a great deal of harm, their total weight is so comparatively small, and the gear-ratio between the engine and the wheels is so moderate that their longevity may quite possibly not be seriously impaired thereby.

◆ ◆ ◆

Not to be Commended for Commercial Vehicles.

It is quite a different matter, however, with commercial vehicles which carry heavy loads, and are geared very low, and we therefore take very serious exception to the enthusiastic proposals put forward at the discussion to employ the engine as a brake in the case of petrol lurries and 'buses. In such cases, the racking action on the transmission mechanism would be so enormous and so serious, if the engine were habitually used instead of the ordinary brakes, that we do not believe any transmission-gear would stand it for very long. To kill the transmission-gear for the sake of effecting economy in brake-blocks is certainly not a very rational proceeding, as the cost of one new transmission-gear would provide the motor 'bus with brake-blocks and brake-drums until the present drivers had retired by superannuation. Dr. Watson's paper is of the highest value as showing what braking effect *can* be obtained from the engine, but it would, we think, be a thousand pities if it were to induce builders of heavy vehicles, lurries and motor 'buses to adopt the principle involved before fully weighing all the *cons* as well as the *pros*. It is only an idea, but we should not be at all surprised if it were even found advisable in the future to introduce some type of free-wheel clutch between the transmission-gear and the driving road-wheels, with the express object of checking all tendencies for the car to drive the propelling mechanism.

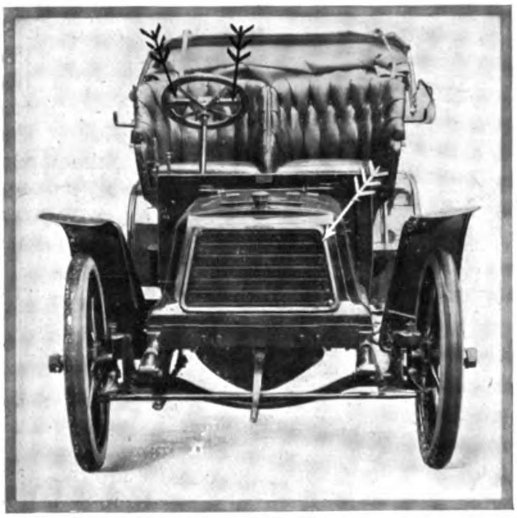
How to Recognise the Cars of To-day.

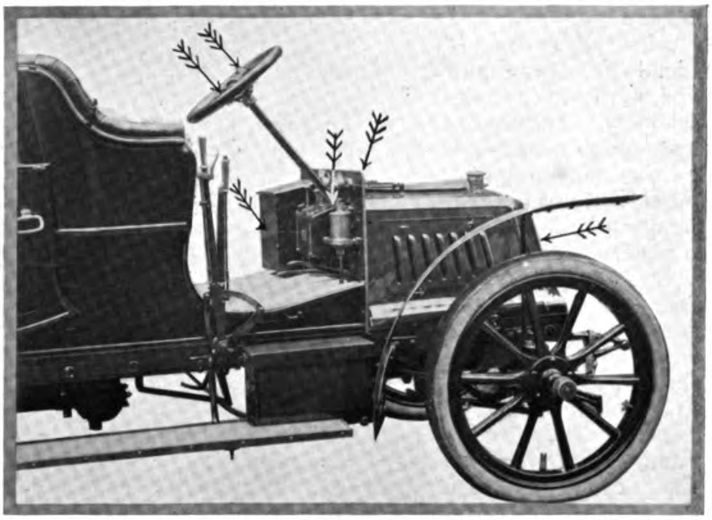
(No. 5).

The Panhard.

(FRENCH)

8-11, 15-20, 24-30 & 35 H.P.





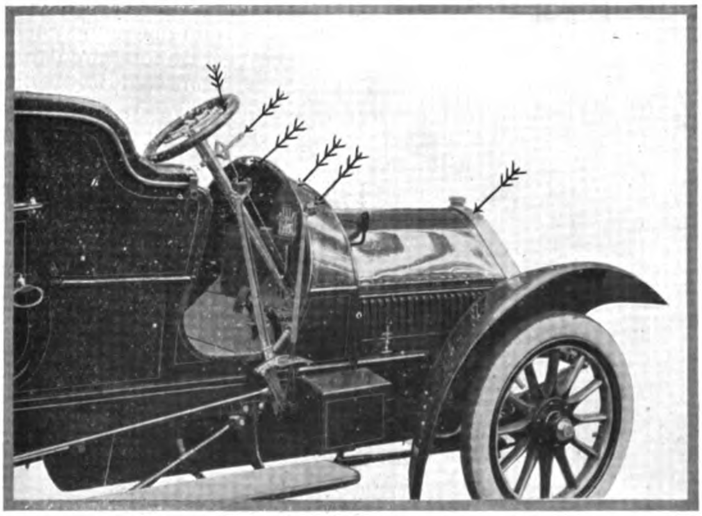
The two smallest models have their RADIATORS formed by finned, horizontal tubes set in a neat framework, but boneycomb radiators of different shapes are fitted on the more powerful cars. On the LOW, STRAIGHT DASH is a wooden BOX containing the MAGNETO, and the STEERING PILLAR passes through the dash-board. All Panhards have a special type of HAND-CONTROL above and across the STEERING-WHEEL.

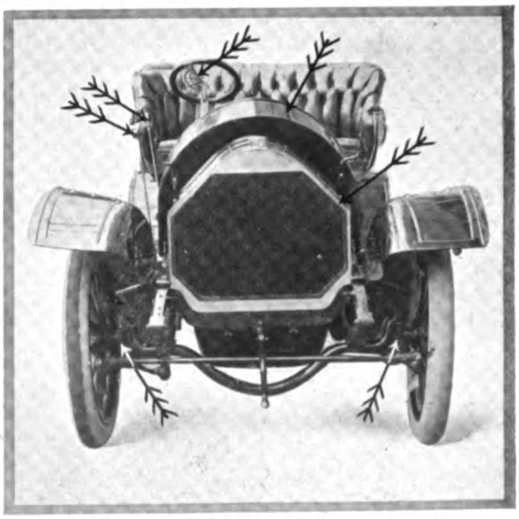
(No. 6).

The Humber.

(BRITISH)

10-12 H.P. & 16-20 H.P.





Both models have RADIATORS AND BONNETS of this distinctive shape, but vertical, finned tubes are used in place of the honeycomb on the smaller. The larger only has the unique CAB-DASH, the forwardly inclined KNOBS ON THE SIDE LEVERS, and the small auxiliary-air HAND-LEVER projecting from the STEERING-PILLAR. All Humber cars have ONE-ARMED STEERING WHEELS. Note the outwardly SLOPING STEERING-HEADS at the ends of the front axle.

THE 16-H.P. CRAWSHAY-WILLIAMS PETROL CAR.

Among the new British firms who first brought their cars before the public at Olympia, in November last, was Messrs. Crawshay-Williams, of the Ashtead Motor Works, in Surrey. They have for some time devoted their attention to the production of touring cars of moderate power, and have also made a study of light vans for delivery work, their standard models at present consisting of a 4-cylinder vehicle of 16-h.p. for pleasure purposes, and a twin-cylinder chassis suitable for taking any type of light commercial body. In general design, both models follow the same lines, having side chains to drive the rear wheels, but it is to a consideration of the touring car that we propose to confine our attention in this article.

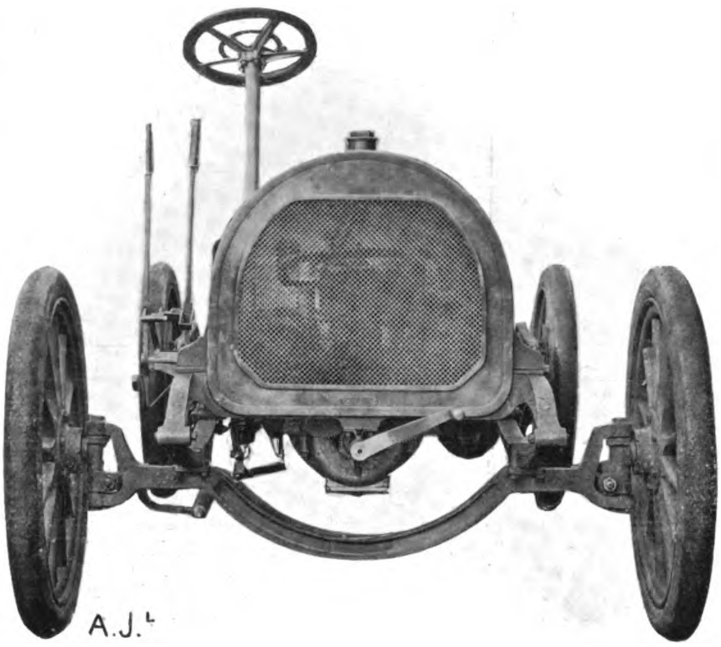


Fig. 1.—Front view of the 16-h.p. Crawshay-Williams Car.

So clearly do our photographs show the arrangement of the various parts, that comparatively little need be said concerning the 16-h.p. chassis as a whole. Fig. 1, for instance, which is a front view — and actually enables the outline of the engine to be seen through the honeycomb radiator—gives an excellent idea of the shape of the radiator and of the forged front axle with its steering-heads; the two steering-heads are fitted with ball-thrust-bearings to take the weight of the car, the stub-axles on which the wheels revolve, have ball-bearings, and the cross-rod that ties the two steering-heads together lies behind the axle, as seen in Fig. 4. Similarly, in Fig. 2, which is a view from the "near" side, it will be noticed that the tapering side-members of the pressed-steel frame present a level surface on the upper side, that the exhaust box is fixed close up, almost midway between the front and rear wheels, and that the chains which drive the rear wheels are kept comparatively short owing to the position of the gear-box. Figs. 3 and 4, which are views from above and beneath, respectively, still further serve to demonstrate the form of construction adopted, both indicating the manner in which the side-members of the frame curve inwards in front, besides showing the short underframe that supports the clutch-gear as well as the engine. These views, in conjunction with Fig. 5—which is taken from an elevated position at the rear of the chassis—show the large (13½-gallon) corrugated petrol tank fixed beneath the frame at the back, and also enable the arrangement of the long semi-elliptic springs to be seen. In Figs. 5 and 6, the upper portion of the gear-box has been removed, and the latter view in particular gives an excellent idea of the change-speed-mechanism enclosed in it. Fig. 6 represents the central portion of the chassis, as seen from above.

The main features of the chassis are the very substantial pressed-steel frame, with its three intermediate transverse members, the Hele-Shaw multiple-disc clutch, with a special cam-action for controlling it, the strongly-built change-speed-gear, with a somewhat original operating mechanism, and the internal brakes that act upon the hubs of the rear wheels.

On the chassis from which our photographs were taken, the engine is of the well-known Simms type, the cylinders having a bore of 95 mm, with a stroke of 110 mm. It is fitted with a low-tension magneto system, and has, combined with it, a gear-driven circulating pump of the centrifugal type. An automatic governor acts direct upon a butterfly throttle-valve in the induction-pipe, but the valve is also subject to the control of one of the small hand-levers that lie above the steering-wheel. The other small lever is connected with the "timing-gear" for the ignition, and both levers work about the same circular quadrant. These levers have quick-thread screws formed upon their sleeves, to give

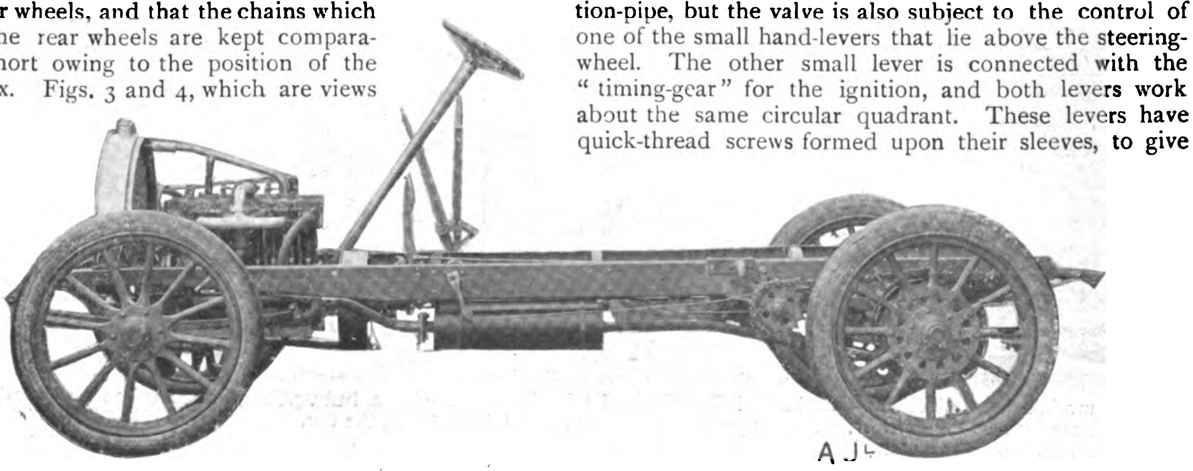

Fig. 2.—View of the 16-h.p. Crawshay-Williams Chassis from the "near" side.

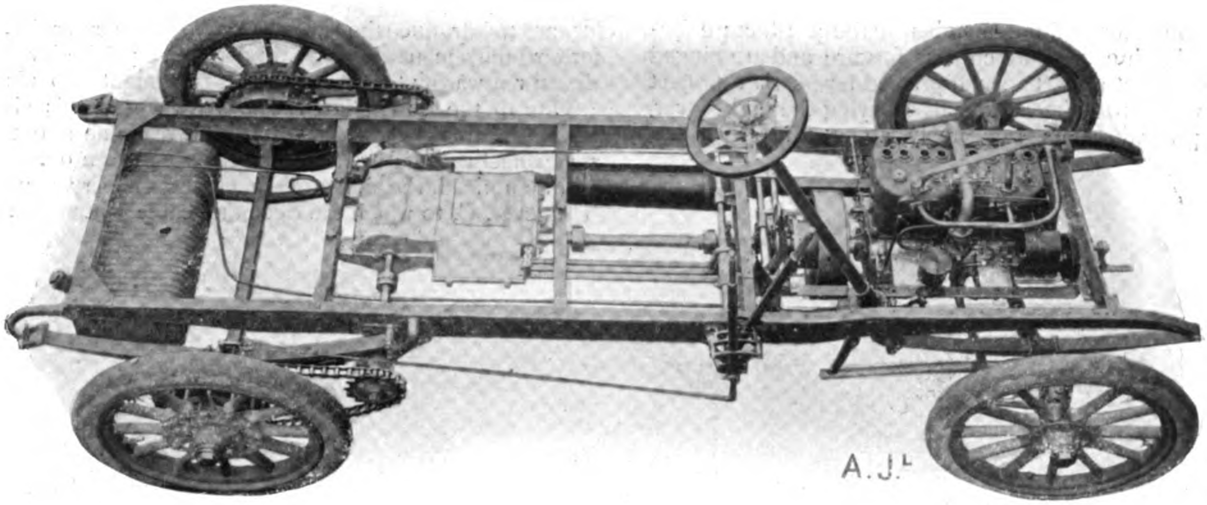

Fig. 3.—The 16-h.p. Crawshay-Williams Chassis, as seen from above.

the necessary up and down motion to the steel cords that pass to the throttle-valve, and to the timing-gear.

For operating the clutch, there are two rock-shafts fitted across the underframe, one of these shafts carrying the clutch-pedal, while the other carries the fork that engages with the sliding portion of the clutch itself. The former shaft is fitted with a cam that engages with a roller on the other shaft, and this roller is provided with an adjustment screw, B (see Fig. 6), for regulating the extent to which its shaft is rocked by the cam. By this arrangement, the pedal is made to withdraw the clutch immediately it is depressed, but the cam merely holds the clutch out of engagement, and so relieves the pedal of any pressure from the clutch-spring when the pedal is further pressed downwards by the driver. Similarly, it may be pointed out that a further advantage is gained owing to the facility with which the pedal can be adjusted relatively to the clutch itself. As will be seen in Fig. 4, the clutch-shaft is supported by a bearing fixed to the frame just behind the operating-mechanism, and there is a flexibly-coupled longitudinal shaft to connect the clutch-shaft with the change-speed-gear. Interconnected with the clutch mechanism is the brake-pedal, so that the clutch is automatically thrown out of action when the foot-brake (on the differential countershaft) is applied; the hand-brake, however, acts quite independently of the clutch.

All three shafts in the gear-box are provided with ball-bearings, which are secured to the lower casting by straps (as seen in Fig. 6), and, therefore, the upper portion of the box can be completely removed without disturbing them. There are, however, inspection doors as well, so that it is not necessary to take off the entire casting in order to make a cursory examination of the mechanism. The lower casting is fixed by a single bolt to the cross-member in front of it, and by two bolts to that immediately behind it, so that it is unaffected by any twisting of the frame. With the same object, flexible couplings are introduced in both halves of the differential countershaft, the ends of which are carried by long plain bearings in much the usual way. The gear itself, which provides three forward speeds and a "reverse," is of that type in which two sliding sleeves are mounted upon the first-motion-shaft, and an intermediate pinion is mounted beneath, so that it can be moved along its shaft. To the left of the first-motion-shaft is the second-motion-shaft (carrying three spur-wheels), and the bevel-pinion for driving the differential

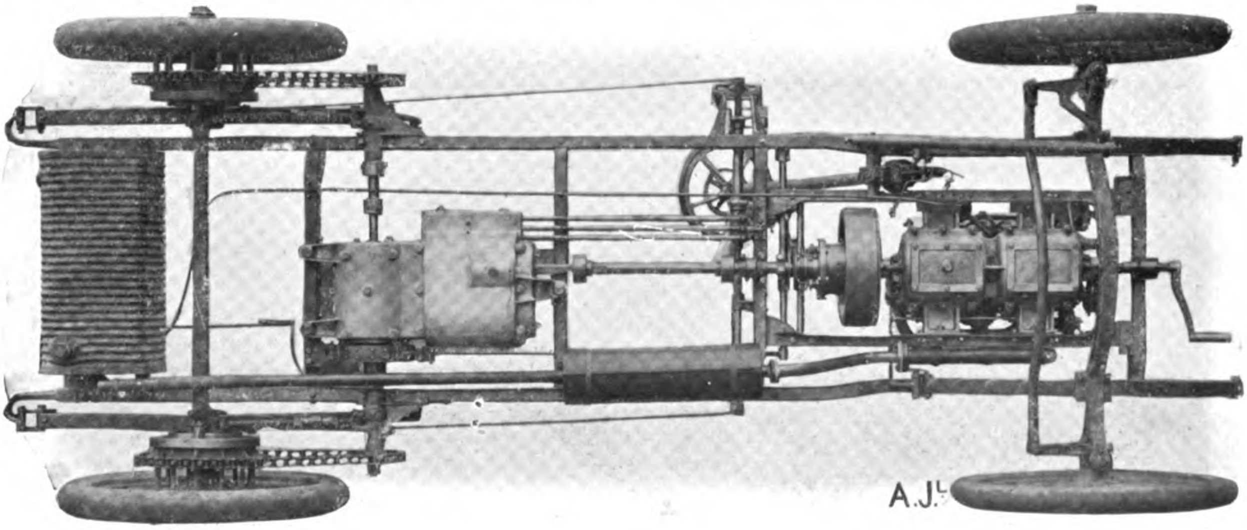

Fig. 4.—View of the 16-h.p. Crawshay-Williams Chassis from beneath.

gear. These three sliding-members in the gear-box are controlled by three rods which pass forward and are hinged at their front ends to small pivoted levers that project downward from the rock-shaft carrying the brake-lever. The pivoted levers ride freely about this shaft, but either of them can be engaged by the horse-shoe shaped carrier, A, which is fitted to the change-speed-lever, and thus whichever gear is required can be introduced. A special arrangement is made for preventing the first-speed gear-wheel from moving sideways when the "reversing" pinion is being slid into mesh with it, and —as our illustrations clearly indicate—the gear-lever works in a quadrant of the 3-slotted "gate" type. In the inner slot—into which the lever can only be moved after the safety-catch has been liberated—a forward motion gives the reverse; in the central slot, the lever has to be pressed forward to introduce the first speed; and in the outer slot, a forward movement gives the third speed, or if the lever is drawn rearwardly the second speed is brought into play.

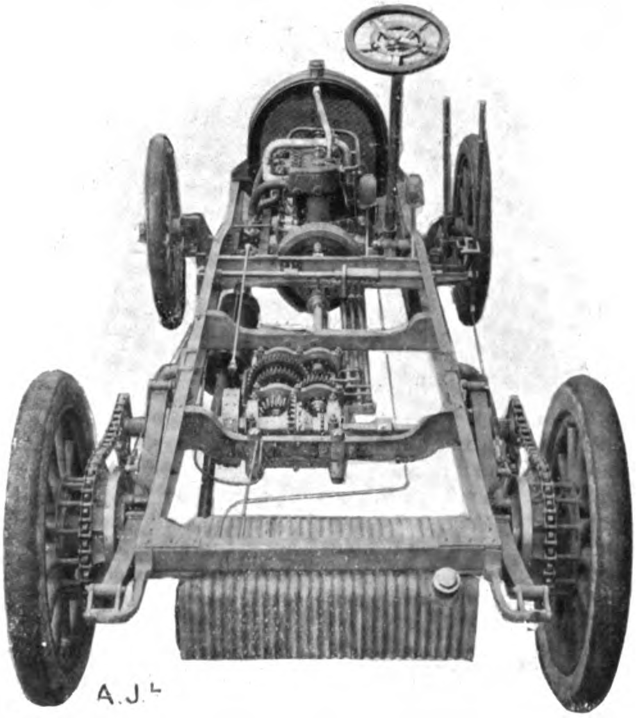

Fig. 5.—Rear view of the 16-h.p. Crawshay-Williams Chassis.

One of the hub-brakes is shown in Fig 7, this view having been taken from the end of the rear-axle, after the road-wheel with its brake-drum had been taken off. As will be noticed, the actuating mechanism is very simple. The lever, C, to which the operating cable is attached, is mounted upon the same rock-shaft as the specially-shaped cam, C^1, and, pressing against this cam, are small rollers mounted on the ends of the two brake-shoes, C^2. The shoes are pivoted to the pin, C^3, at their lower ends, and are normally held clear of the surrounding brake-drum by the spring, C^4, the cam, C^1, forcing them apart when it is rocked about its axis.

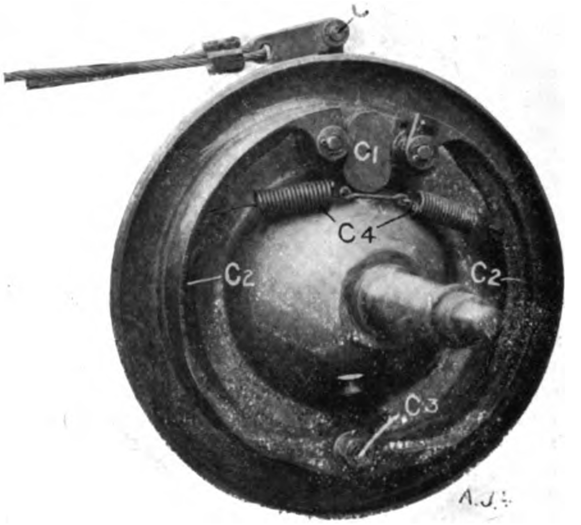

Fig. 7.—One of the external expanding hub-brakes on the Crawshay-Williams Chassis.

The standard 16-h.p. chassis has a wheel-base of 8 ft. 8 in., a track of 4 ft. 7 in., and the front and rear tyres are 870 mm. by 90 mm. and 875 mm. by 105 mm. respectively.

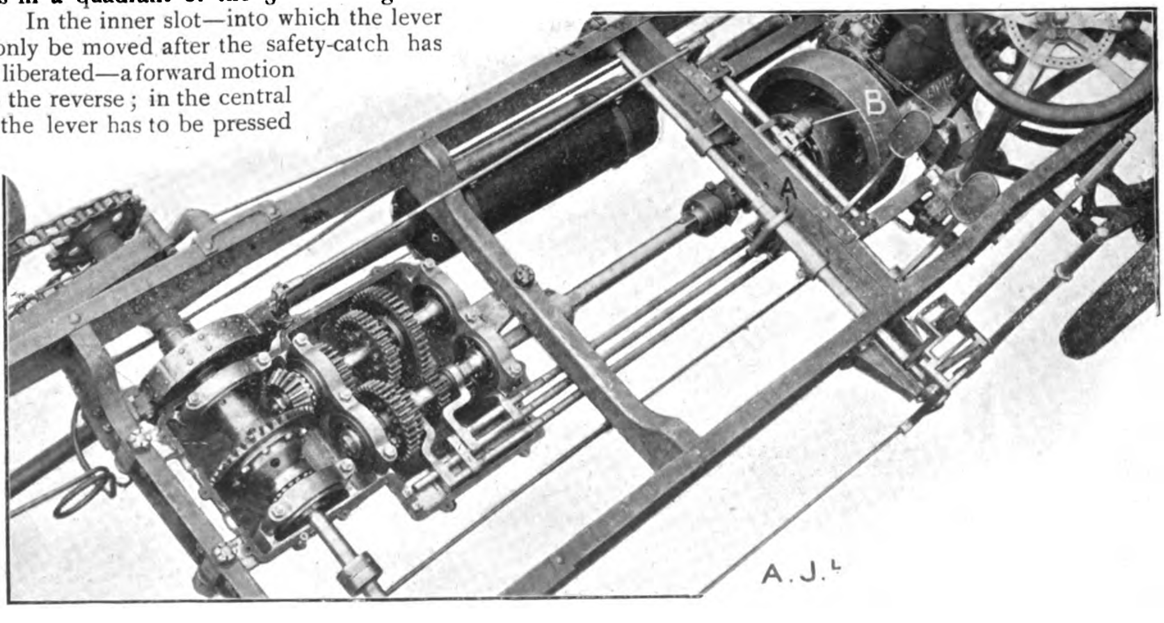

Fig. 6.—The central portion of the 16-h.p. Crawshay-Williams Chassis, as seen from above, showing the gear-box with the upper half removed.

THE WESTMACOTT PARAFFIN VAPORISER.

PARTICULARLY for marine work, there is an ever increasing demand—which has unfortunately not hitherto been altogether satisfied—for a thoroughly satisfactory vaporiser whereby ordinary lamp-oil can be substituted for petrol with internal combustion engines, and, as is well known, a large number of makers and inventors are busily engaged in attempting to solve what has for some years proved to be an exceedingly tough problem. Amongst the many devices of this kind which have been more or less recently introduced, is that which was fitted by Messrs. Woodnutt and Co. to the boat they ran in the Reliability Trials at Southampton this year; and it is of this vaporiser—the invention of Mr. Alfred Westmacott—that we are now able to give full particulars.

It is of that type in which the oil is drawn up through a mixing-chamber by the main volume of the entering air, and in which the mixture thus formed is caused to pass through a heated chamber before being led to the induction-valves of the engine. It also has means provided by which the flow of oil can be directly adjusted, and is fitted with a spring-loaded valve which tends to maintain an approximately constant richness of the mixture, in spite of varying load, by admitting a greater or less quantity of auxiliary air into the induction-pipe between the vaporiser proper and the throttle-valve.

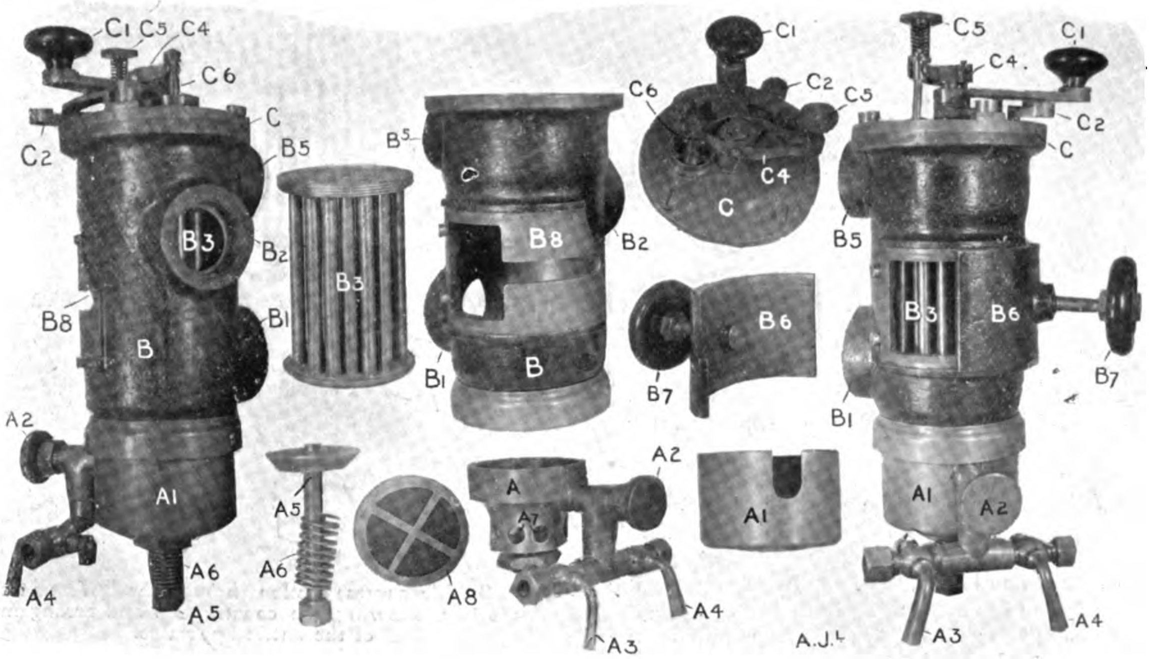

Fig. 1.—Two views of the complete "Westmacott" Vaporiser, with other views showing some of the more important component parts grouped between them.

In Fig. 1 the entire apparatus, both complete and in parts, is shown, from different points of view, in such a way that its construction is rendered almost self-evident, while in Fig. 2 we give a couple of additional views of the throttle-valve with the auxiliary air-valve; in Fig. 3 is a transverse section of the entire mechanism. Referring to these illustrations, it will be seen that there is a lower valve chamber, A, an intermediate heating-chamber, B, and that the engine regulating-valves are carried above by the cover-plate, C. Inside the valve-chamber, A, is the atmospherically-operated valve, A^5, which is normally held down upon its seat by the adjustable external spring, A^6, and this valve not only controls the passage of the main air supply entering through the ports, A^7, but also prevents the oil from flowing into the valve-chamber. For this latter purpose the oil is led to a hole drilled through the seating of the valve, and the needle-valve, A^2, which regulates the flow, is arranged close up to the seating. The valve, A^5, is of course lifted off its seat by the suction of the engine, when running, and the air and oil are then simultaneously drawn up into the heating-chamber, B, where the former is actually vaporised.

Around the valve-chamber, A, there is a light metal casing, A^1, to prevent any water from finding its way down to the air ports, A^7, in rough weather; and immediately above the valve, A^5, there is a mixing-ring, A^8, having conical steps turned around its interior, as seen in Fig. 3, and several layers of wire gauze fitted right across the top of it (see Fig. 1). This portion, A^8, serves as a mixing device for bringing the oil and air intimately into contact with one another.

The heating-chamber, B, forms a kind of exhaust-gas jacket, inside which is fitted a group of small tubes, B^3, these tubes being arranged like those in an ordinary fire-tube boiler. The tubes with their end plates form a single, and separately detachable, unit, which can at any time be screwed up out of the casting, B, and removed for cleaning. The upper plate has a screw thread for this purpose, while the lower one is provided with a conical valve-seating that makes a gas-tight joint with the main casting. When the tubes are in place, the whole of the explosive mixture is compelled to pass up through them into the upper chamber, B^4, and, all around the tubes, are led hot exhaust-gases from the engine. The exhaust-pipe enters the casting, B, at B^1, and the outlet-pipe is connected at B^2.

When the engine is running, the tubes, B^3, are at all times kept hot by the exhaust-gases alone, but when it is desired to start the engine initially with paraffin, it is necessary to heat them up at first with a blow lamp. For this purpose, there is an easily opened door, B^6, fitted in the side of the chamber, B, and this is normally locked in place by the hand screw, B^7, the inner end of which rides in the slot, B^8. A start can, however, be made from cold, by using petrol for a short time before turning on the paraffin, and it is for this reason that the two cocks, A^3 and A^4, are provided in conjunction with the needle-valve, A^2.

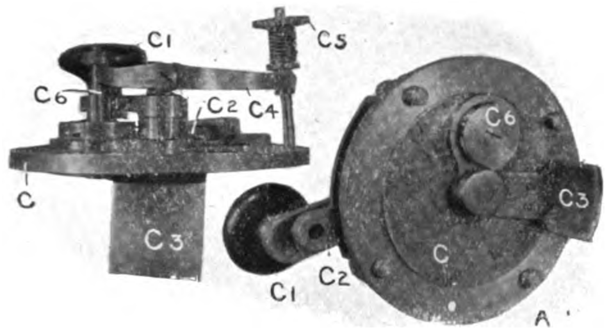

Fig. 2.—Side view, and a view from beneath, of the throttle-valve, C^3, and the auxiliary-air-valve on the "Westmacott" Vaporiser.

For regulating the speed of the engine, a throttle-valve of very simple construction is employed, this merely consisting of the shutter, C^3, which can either be controlled by the hand-lever, C^1, or by an automatic governor acting on the lever, C^2. Both levers have the effect of causing the shutter, C^3, to open or close the passage of the mixture from the chamber, B^4 to the induction-pipe, B^5, for both these levers are fixed to the spindle that carries the shutter. A special arrangement, however, is made by which the action of the auxiliary-air-valve, C^6, is modified to suit various positions of the throttle. To this end, a quick acting thread is cut on the spindle of the throttle-valve, and pivoted to the nut riding on this thread, is the lever, C^4, that is interposed between the adjustable spring, C^5, and the auxiliary-air-valve, C^6. The spring, C^5, at all times tends to keep the valve, C^6, upon its seat, but the strength of this spring is automatically varied by the screw thread above referred to.

It is in this form that the Westmacott vaporiser is at present manufactured for use with marine motors, and it appears to be giving very great satisfaction on those engines to which it has been applied. Approximately it gives a fuel consumption of about ·78 pint per b.h.p. hour, on an engine developing about 18 h.p. We understand that, although every facility has been made for readily cleansing the tubes, B^3, it is seldom necessary to do so in practice.

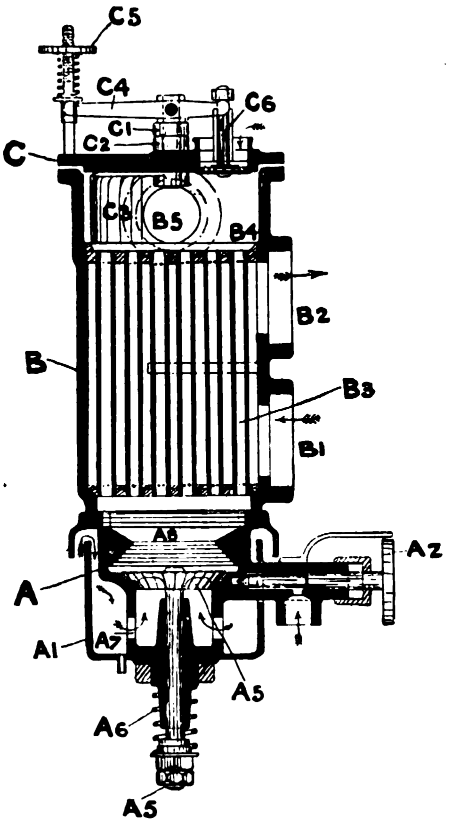

Fig. 3.—Transverse section through the "Westmacott," Vaporiser, showing the construction and arrangement of the entire apparatus.

⊛ ⊛ ⊛ ⊛

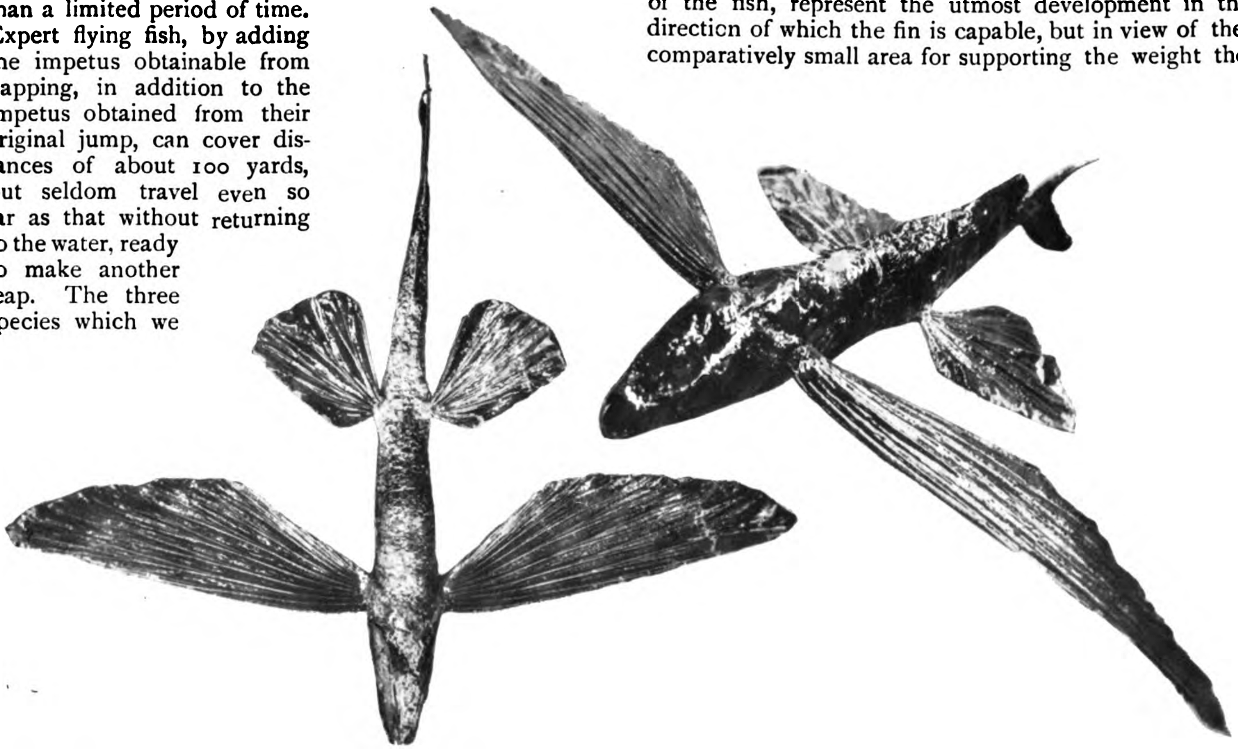
When no Obstruction is an Obstruction.

It has now been held by a Metropolitan magistrate that you may create an obstruction though nothing is obstructed. Formerly, and we believe even still by the great majority of magistrates, it was held that if a vehicle of any kind is drawn up at the kerb obstruction to other traffic must be proved to support the summons for obstruction. But Mr. A. W. S. Aldridge was summoned at the South-Western Police Court for allowing his motor car to stand for 2¾ hours outside his house in Conyers Road. In the hearing of the case the constable for the prosecution disclosed the interesting information that cabmen were usually allowed three-quarters of an hour before being summoned. He admitted at the same time that no traffic and no passengers were obstructed, but Mr. Grey nevertheless found Mr. Aldridge guilty of a technical offence. Of course to permit motor cars to stand in front of their owner's house for unlimited periods would be liable to abuse, but we still think there should be evidence of someone being inconvenienced or obstructed, before punishment of even a mere formal kind like the *1s.* fine and *2s.* costs which Mr. Grey ordered in this case, should be imposed. There are streets in the suburbs with only one or two houses in them. Surely a motor car standing in one of these for a whole day, or a whole week, would be doing no one the slightest injury.

AERONAUTICS.

Flying Fish as Instructors.

ACTING upon a suggestion made to us by Mr. A. V. Roe, whose aeroplane model, based upon the Wrights' aeroplane, we illustrated a week or two ago, we this week produce some photographs of flying fish, which may be said to some extent, at any rate, to have solved the problem of gliding. There are a number of different species of flying fish. It is a fish that has developed its fins into aeroplanes, with which it can accomplish (by jumping out of the water) extended glides, and even prolong these glides to a certain extent by flapping. But the flying fish is not really a flyer, in the sense in which the bird or the bat are flyers, for he cannot keep himself in the air for more than a limited period of time. Expert flying fish, by adding the impetus obtainable from flapping, in addition to the impetus obtained from their original jump, can cover distances of about 100 yards, but seldom travel even so far as that without returning to the water, ready to make another leap. The three species which we illustrate—thanks largely to the very great courtesy of Dr. Ridewood, who gave us every facility for taking our photographs at the Natural History Museum, South Kensington—are the *Exocoetus Lineatus*, captured off St. Vincent, in the Cape Verd Islands (two views, one from beneath, one from above); the *Exocoetus Cahiensis*, found in the Atlantic Ocean; and the *Exocoetus Spilapterus*, found in the Indian Ocean.



Views—showing the upper part diagonally, and the underside squarely—of a Flying Fish (Exocoetus Lineatus) found off St. Vincent, Cape Verd Islands. Our photographs—taken at the Natural History Museum, South Kensington, with the kind assistance of Dr. Ridewood—clearly show the two sets of "wings," or aeroplanes, that enable this curious type of fish to "glide" a considerable distance above the surface of the water. This fish is 19 in. long, and measures 21¼ in. from tip to tip of the "wings."

An interesting feature is that in addition to the two large aeroplanes or wings in front, which are designed evidently to carry the bulk of the weight (but which are too far forward to give an effective balance), smaller aeroplanes towards the tail are added. They are, however, much shorter and smaller in size, and the arrangement of the whole suggests that the weight of the fish is hardly properly distributed between the aeroplanes. This may, perhaps, to some extent explain the shortness of flight accomplished. But it is encouraging for human experimenters to be reminded of the fact that not only have birds, which are a race to themselves, accomplished flight, but that the same problem has also been solved by the bats, which are mammals, while in addition to these two successful aeronauts we have the flying fish.

When we consider the purely gliding action of the flying fish, the careful observation of his "wings" becomes a subject of keen interest. It will be noticed that they are very flat, straight, rigid, and hardly at all domed. In this respect they differ entirely from the feathered wings of all long-distance flying birds, which are curved upwards and inwards in front in a marked degree. Probably the "wings," if they can be so called, of the fish, represent the utmost development in that direction of which the fin is capable, but in view of their comparatively small area for supporting the weight they have to carry, a flying fish may claim to rank as a decidedly efficient "glider."

A Spanish Airship.

THE Lebaudy people are going ahead, as we chronicled last week, and now we are threatened with an apparition of another airship on the Lebaudy lines, designed by Capt. Kindelan for the Spanish Government. A good deal of secrecy is being maintained about the new airship, but it is understood that the envelope will be constructed of caoutchouc tissue, like the Lebaudy airship, will have a length of 35 metres and a diameter of 6 metres, and in this respect will be of about the same size as Santos Dumont's No. 6, with which he won the Deutsch Prize. The amount of gas it contains is approximately the same. It resembles more the Lebaudy than the Santos Dumont machine, however, by having a very short hull, mounted close under the gas vessel, but differs from the latter in not having any fixed aeroplanes, or other rigid constructions, mounted between the motor and the gas vessel. The Spanish airship will be provided with two Levavasseur motors of extreme lightness, developing 24 h.p. each. The airship is intended for experimental purposes, and a new feature will be an adjustable balance weight for preventing "pitching."

The Italian Government Following Suit.

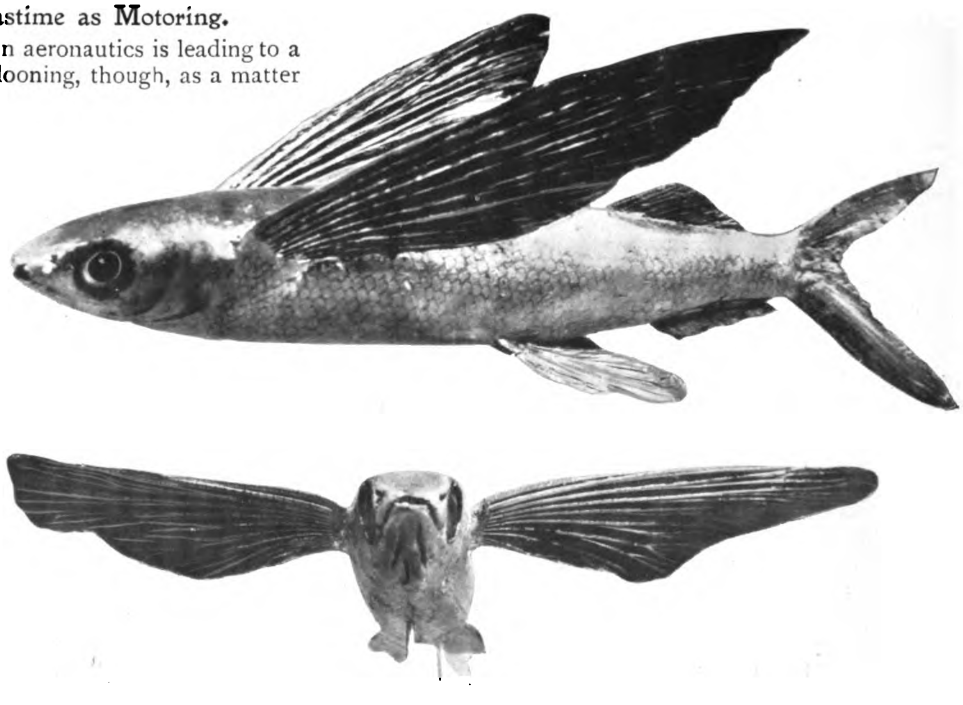
ANOTHER airship of the navigable balloon type, entitled the Italia, is being constructed under the auspices of Count Almerico de Schio, while a company is being formed at Parma to build an airship according to the designs of Capt. Frassinnetti.

Another French Aeroplane.

THOUGH activity has thus been concentrated mainly upon the navigable airship, the aeroplane is not being altogether neglected, and another experimenter has appeared in the field—M. Albert Bazin, of Marseilles—with a machine of the heavier-than-air type. The machine consists, we understand, of two wings fixed together (possibly this means two superposed aeroplanes), and is provided with a hull in which the aeronaut takes his place. Wings for controlling the machine and ensuring its stability are mounted behind, and the total span is 11 metres from point to point, and 1½ metres in the direction of movement. This suggests a machine resembling the Wright or Chanute aeroplane in general appearance, but the tail is apparently much larger, being some 5 metres in length. At any rate the apparatus is well thought of by Capt. Ferber, who is said to have purchased it from M. Bazin with a view to experimenting with it.

Ballooning as Cheap a Pastime as Motoring.

THE increasing interest in aeronautics is leading to a more general interest in ballooning, though, as a matter of fact, the two subjects have very little in common, and it is a curious fact that none of our veteran balloonists have effected anything noteworthy even in the navigable airship line of research, much less in regard to aeroplane. At the same time, ballooning may have its uses in familiarising would-be experimenters with the sensations of being up in the air. It is, at any rate, a delightful and health-giving pastime, and it is, accordingly, satisfactory to learn that with the price of balloons coming down very markedly, the cost of gas at first hand becoming less and less, ballooning, as a sport, is being brought within the reach of anyone who can afford the expenditure involved in even a moderate-sized motor car In fact, as has been pointed out, you can take a balloon trip across the Channel or so, at a cost that does not practically exceed the expenditure involved in a Saturday to Monday trip to Brighton, while if you are a member of the Aero Club, you can do it cheaper still.



Two other species of Flying Fish, forming a part of the collection at the British (Natural History) Museum. The side view represents a fine specimen (13½-in. long) of an Exocoetus Cahiensis, found in the Atlantic Ocean, while beneath is an excellent view from the front showing an Exocoetus Spilapterus (from the Indian Ocean) with "wings"—10¼-in. from tip to tip—outstretched.

Activity in Airships.

ACTIVITY seems to vary its direction in the aeronautical world as much as in others. Latterly we have had almost a superfluity of aeroplane experimenters, none of whom, however, except the Brothers Wright, have done anything really very epoch-making. And now the navigable balloon seems once again to have become the fashionable amusement, at any rate on the Continent. Possibly this is due to the exploits of the Lebaudy airship. The German Government is bent on making good the failure of the Zeppelin machine, and is concentrating its energies on the construction of a new airship of the navigable balloon type.

A German Navigable Balloon.

IT is to Major August von Parseval, a prominent aeronaut, who has distinguished himself in the design of various types of kites, that the German Government owes the designs for the new airship of the navigable balloon type with which, as we have explained, the shortcomings of Zeppelin II. are to be made good. The airship comprises the usual parts of a separate gas-vessel with a rudder mounted at its extreme end, and a hull carrying the propellers and motors. The shape of the gas-vessel is a good deal like that employed by Count Zeppelin, being cylindrical throughout most of its length and rounded off at its ends. It is 48 metres in length and measures 8½ metres in diameter. Its cubic capacity is 24,000 cubic metres, and it is provided with two ballonettes to keep the surface of the gas-vessel tight, the ballonettes being kept full of air by means of fans driven from the motor. Aeroplanes are employed to give steadiness to the movements of the airship, one on each side, underneath the gas-vessel, and a third one at the rear. The car is of aluminium and steel, and is capable of carrying two, or at most three, passengers in addition to the motor and accessories. The propeller is placed above the car. It is thus saved from coming into violent contact with the ground when alighting. The motor which supplies the propulsive power is a 90-h.p. Mercedes, weighing 40 kilogs. A peculiarity of the construction of the propeller is said to be that the blades are stiffened by centrifugal force when rotating. Major Parseval anticipates accomplishing a speed of some 50 kiloms. per hour. The first tests will be made with the new machine in the neighbourhood of Berlin in the approaching spring.

Towards the Pole.

The progress of the Wellman Polar airship appears to be satisfactory, and it is now understood that, in addition to the 50-h.p. motor, it will be provided with a 25-h.p. additional motor and a smaller screw. The explorer's intention is to employ the airship with a trailing guide-rope at a quite moderate elevation, starting preferably with the wind, and merely attaining sufficient speed through the air to render the airship thoroughly controllable. In case of an accident to the principal motor or propeller, he will be able to proceed at diminished speed with the subsidiary equipment, while, should it become at any moment imperative to proceed at higher speed, he can work the two together, in which case it is estimated that his speed will increase from the ordinary 25 kilometres to some 32 kilometres per hour. Mr. Wellman intends spending some weeks at his base on Spitzbergen, and thoroughly experimenting with the airship before making his actual start for the Pole.

The Death of M. Archdeacon.

All aeronauts, and a great many other people, too, will learn with the most profound regret of the sudden death of M. Edmond Archdeacon, the well-known Nationalist Member of the Chambre, and one of the most enthusiastic experimenters and writers on all problems connected with the conquest of the atmosphere. M. Archdeacon was well-to-do, and gave a prize for the first aeronaut to cross the Pyrenees in a balloon, which was won by Signor Durot, a month ago. In combination also with M. Deutsch, he has offered a prize for aeroplanes and steerable balloons, which has yet to be competed for. M. Archdeacon was a convinced disciple of the aeroplane method of tackling the problem of aerial navigation, and has been, for some time back, experimenting with various types of aeroplanes, till the news of the exploits of the Wright Brothers induced him to give up his practical work, owing to his conviction that the problem had now been satisfactorily solved.

* * * *

War Office Registration of Heavy Vehicles.

Some little time back we drew attention to the extent to which the elimination of the horse from public service vehicles is presenting a serious problem to the military authorities, and referred to proposals which had been put forward to the effect that the War Office would be well advised to replace the registration of horses for military service, which has been the system hitherto adopted, by the registration of heavy motor vehicles for use in war time. The idea, of course, is exactly similar to that adopted by the Navy in regard to the steamship lines, which receive annually a certain "subsidy" on the understanding that they are to place their vessels at the service of the Navy should war break out. The War Office has now addressed a letter to the Motor Van and Wagon Users' Association proposing a scheme of this kind, and this letter has been forwarded by them to a number of owners of commercial vehicles, asking them whether they would be prepared in general to support the War Office scheme, what their views are as regards a fair annual sum, in respect to each heavy motor car registered, and what proposals (if any) they have to make for the improvement of the scheme.

The broad outlines of the Government scheme are as follows:—

> The owner of registered heavy motor vehicles, in consideration of which registration a small sum should be paid annually by the War Office, to agree to allow the War Department to make use of the vehicles for a time or to purchase them on previously arranged conditions.
>
> The rights which the War Office would then enjoy, would be to hire the vehicle for peace manœuvres for a certain number of days in each year, and, in times of war, the vehicles would be purchased outright by the Government if required for foreign service, while if used for home defence, they could be bought back at a valuation by the owner after the War Department had finished with them.

The War Office is to be congratulated on adopting this initiative, and as there are no doubt a large number of heavy vehicle owners who would be prepared to avail themselves of the proposals, a satisfactory scheme is likely to be agreed upon as the result of mutual discussion at an early date.

The Renault "Direct-Drive" Patent in France.

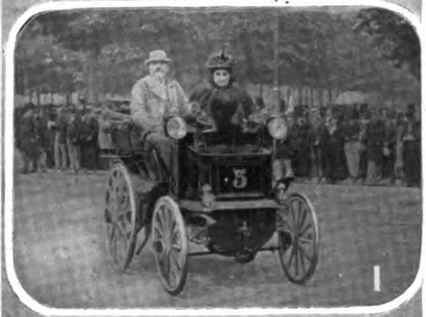
We have received from the Secretary of the British Empire Motor Trades Alliance a translation of the provisional agreement that has been entered into between the Renault firm and twelve other French manufacturers, and of which some particulars have already been given in The Automotor Journal. From it, we are now able to state definitely that no chain-driven cars, nor any in which there is gearing between the differential and the road wheels—even though a direct-drive is obtained in the gear-box—are deemed to infringe the Renault patent. Another significant provision is that the Renault firm undertake to fix their terms of royalty on foreign vehicles, imported into France, at a figure that shall be at least twice that obtained from French licensees. The Paris correspondent of the B.E.M.T.A. further indicates the feeling in France on this matter; they hope to annul the French patent under Article 18, in view of the Whitney patent, but think that that patent will not invalidate the English Renault patent if Renault takes the precaution of amending it before taking action.

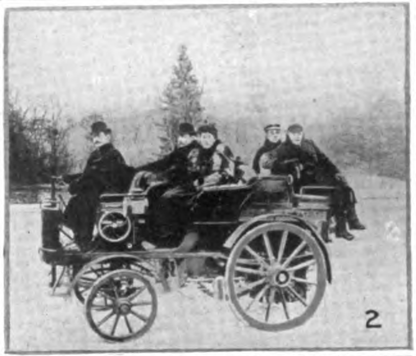
Edinburgh Looking Ahead.

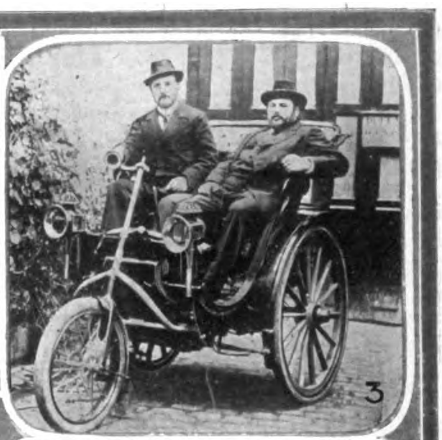
On the motion of two Town Councillors the Edinburgh Tramways Committee have had remitted to them, to consider and report on, the utility of motor 'buses for public service, safety, and convenience; and whether, in view of their rapid improvement, past and prospective, further laying down of tramways may be a waste of public money.

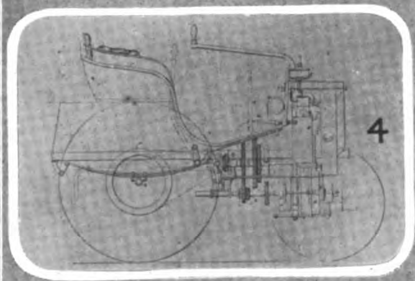
THE HORSELESS CARRIAGE—1885-1905.

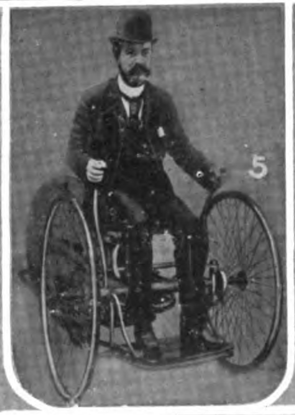
An Interesting Historical Review.

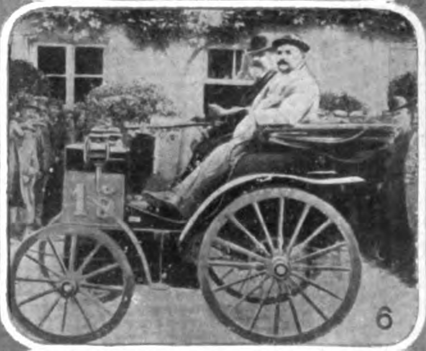


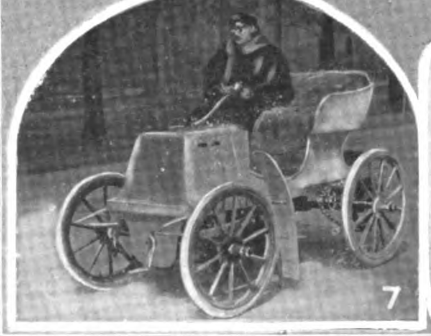


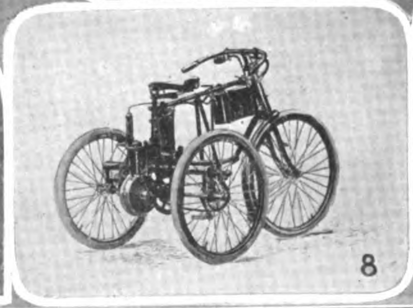


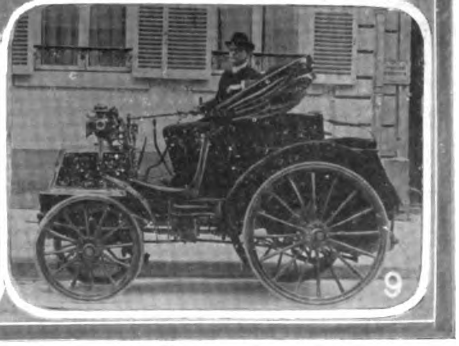












ON Wednesday of last week (February 14th) before a meeting of the Society of Arts, Mr. Claude Johnson read a very entertaining paper, entitled as above, the paper being accompanied by a very large number of lantern slides, representing well-known people as well as celebrated cars. Covering so wide a field, and extending over the twenty years that have seen the entire development of the petrol car, the lecturer was compelled to confine himself to a series of brief references to the more important events of that period, the result being an historical review of the rapid rise of an extremely remarkable industry. Apart from the permanent value of the paper to those who are not already acquainted with the progress of the movement and have not followed its development in greater detail than is possible in so comparatively short a lecture, motorists were afforded an excellent opportunity for once more renewing their acquaintance with many old friends. It is only too easy to forget even the leading characteristics of the earlier types of vehicle, but there is always much to be learnt by looking at them again in the light of present day knowledge. For this reason, we reproduce a few of the more interesting illustrations of early vehicles which were thrown upon the screen during the evening, and below we give the necessary particulars by which they can be identified. Apropos of the value of these early records, concerning the design and construction of the pioneer vehicles, Mr. Johnson put forward the suggestion that the Society of Arts might use its influence in the getting together of a collection of as many of these old vehicles as could be still secured. He stated that he had found the very greatest difficulty in obtaining any detailed information about them—even from the manufacturers themselves—and he referred to the unsuccessful attempts that had hitherto been made by himself and by others to induce either the Government or the Committee of the Automobile Club to take sufficient interest in the matter, or to make any move in this direction. A suggestion of the kind was put before the Science and Art Department at South Kensington some years ago, and the club had frequently been urged to form a collection of scale models and photographs.

EXPERIMENTS ON THE USE OF THE ENGINE AS A BRAKE.*

By W. Watson, D.Sc., F.R.S.

THERE having been a considerable amount of discussion in the automobile papers on the use of the engine as a brake, I think that some quantitative experiments on the point may be of interest. Further, I have endeavoured to show by experiment exactly how the power absorbed is spent. Not having any means of measuring the loss which takes place in the transmission gear between the engine clutch and the road wheels, I have had to content myself with measuring the power absorbed by the engine alone, but I see that some experiments by Pétard show the efficiency of transmission to vary from 76 per cent. on 2nd speed to 89 per cent. on top speed with direct drive.

The engine used for the experiments is a comparatively slow-running 2-cylinder 4-cycle engine, with mechanically-operated inlet valves, and is governed on the throttle, the lift of the valves being fixed. The bore is 88·9 mm. (3·5 in.), and the stroke 101·6 mm. (4 in.), the cranks being at 180 degs. The engine was coupled up by means of a belt to an electric motor, and the power taken by the motor was deduced from the readings of a standard ammeter and voltmeter placed in the circuit.

In order to be able to apportion the power required to drive the engine between that spent in overcoming friction and that spent in doing work on the air drawn into the cylinders, it was necessary to take indicator diagrams. These were obtained by means of a Hospitalier-Carpentier manograph. The general arrangement of the engine and manograph is shown in Fig 1. The manograph, A, is connected by a short branched tube with the cocks, C, so that either cylinder can at will be connected to the instrument. The reciprocating motion corresponding to the piston travel is communicated by means of a roller chain and two sprockets, a clutch, D, being placed between the upper sprocket and the manograph. This clutch can engage in two positions 180 degs. apart, and the reason for using it is illustrated in Fig. 2. This figure represents two diagrams taken immediately one after the other; but the connection between the manograph and the engine through the clutch has been altered, so that while in one case the explosion takes place when the spot of light is at one extremity of its path, in the other it takes place when the spot is at the other extremity, the photographic plate having been slightly displaced between the two, so as to separate the diagrams to a certain extent. It will be noticed how the diagram is distorted at one end. Thus, in the left-hand side the pressure line, in place of being vertical, is very much inclined, and, further, the scale is contracted at this end. If, however, all diagrams are taken with the peak of the diagram to the right, the distortion has not much effect on the area enclosed, since the pressure at the end of the stroke is comparatively small.

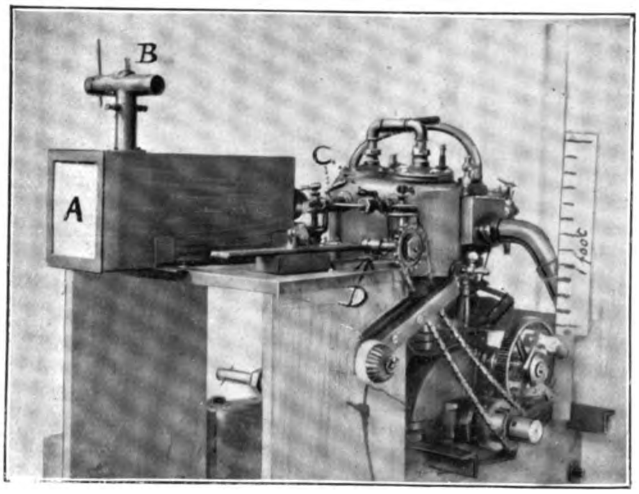

Fig. 1.

A typical diagram for the engine when developing its full power is shown in Fig. 3. This diagram was taken when the speed was 700 revolutions a minute, and the mean effective pressure is 6·14 kilogs. per square centimetre (87 lb. per square inch), the i.h.p. being 5·94. It will be noticed that the exhaust and inlet strokes take place almost exactly at atmospheric pressure, for the valves being of ample size, very little throttling takes place. On this and the other diagrams the inlet stroke is indicated by a single arrow head, the compression stroke by two, the working stroke by three, and the exhaust by four.

All the braking experiments have been made with the engine running at 590 revolutions per minute, and with the temperature of the cylinders about 50 deg. Cent. The speed having been adjusted by means of a variable resistance in the motor circuit, the watts absorbed by the motor were obtained by reading the ammeter and voltmeter. The watts required to run the motor light having been measured, and likewise the armature resistance, it was possible to deduce the power taken to drive the engine.

The first experiment consisted in measuring the power required to run the engine when no variations in pressure took place in the cylinders, the whole of the power being absorbed in doing work against the friction of the moving parts of the engine. In order that the pressure should not appreciably vary in the cylinders, the plugs over the valves were removed, when no measurable change of pressure was shown on the manograph. The power required to drive the engine was 0·75 h.p. (see table below).

TABLE.

H.-P. at 590 revolutions per minute.

	To drive engine.	After deducting friction.	Indicated.
1. No compression	0·75	—	—
2. Throttle open	1·03	0·28	0·27
3. Throttle closed	1·22	0·47	0·46
4. Throttle open, compression cocks half open	1·39	0·64	0·70
5. Throttle closed, compression cocks half open	1·49	0·74	0·79
6. Throttle open, compression cocks full open	1·63	0·88	0·91
7. Throttle closed, compression cocks full open	1·69	0·94	0·94
8. Throttle open, exhaust valve always shut	[1·60]	—	0·88
9. Throttle open, exhaust valve open during third stroke	[2·40]	—	[1·65]

Next, the valve plugs having been replaced, the power required to drive the engine in its ordinary running condition, with the throttle full open, was found to be 1·03 h.p. Hence, deducting the 0·75 h.p. required to overcome friction, there remains 0·28 h.p. as the power expended in sucking air into the cylinders, compressing and expanding this air very nearly adiabatically, and then forcing it out through the exhaust. The corresponding indicator diagram is shown in Fig. 4. It will be noticed that in the expansion stroke (No. 3) the pressure falls a little below the corresponding pressure in the compressson stroke (No. 2). This is due to the loss of heat to the cylinder walls and to slight leakages past the valves, piston rings, &c. The area included is, however, very small, a larger area being included between the induction and exhaust lines. It should be noted that the pressure scale of Figs. 4 to 10 is considerably more open than in Figs. 2, 3 and 11, a thinner steel disc being used in the manograph. The total power corresponding to the areas enclosed in Fig. 4 is 0·27 h.p. This value agrees very well with the additional power expended in driving the engine—namely, 0·28 h.p.—indicating that this additional work is simply due to the work done on the air.

In Fig. 5 is shown the result of closing the throttle. Here the pressure on the induction stroke sinks considerably below atmospheric pressure, and the branches 1 and 4 of the curve enclose a considerable area. The indicated horse-power is 0·46, while the power required to drive the engine is 1·22 h.p. After deducting the work done against friction we get 0·47 as the additional power required on account of the work done on the air in the cylinder, which, again, agrees very well with the indicated horse-power.

In Fig. 6 is shown the indicator diagram obtained when the throttle is open and the compression-cocks are half opened. The cocks being half open is equivalent to the interior of the cylinder being in free communication with the external air by means of a hole $\frac{3}{16}$ of an inch in diameter. The indicated horse-power is now 0·70, while the power required to drive the engine is 1·39 h.p., the additional power required on account of the work done on the air being 0·64 h.p. On closing the throttle, keeping the compression-

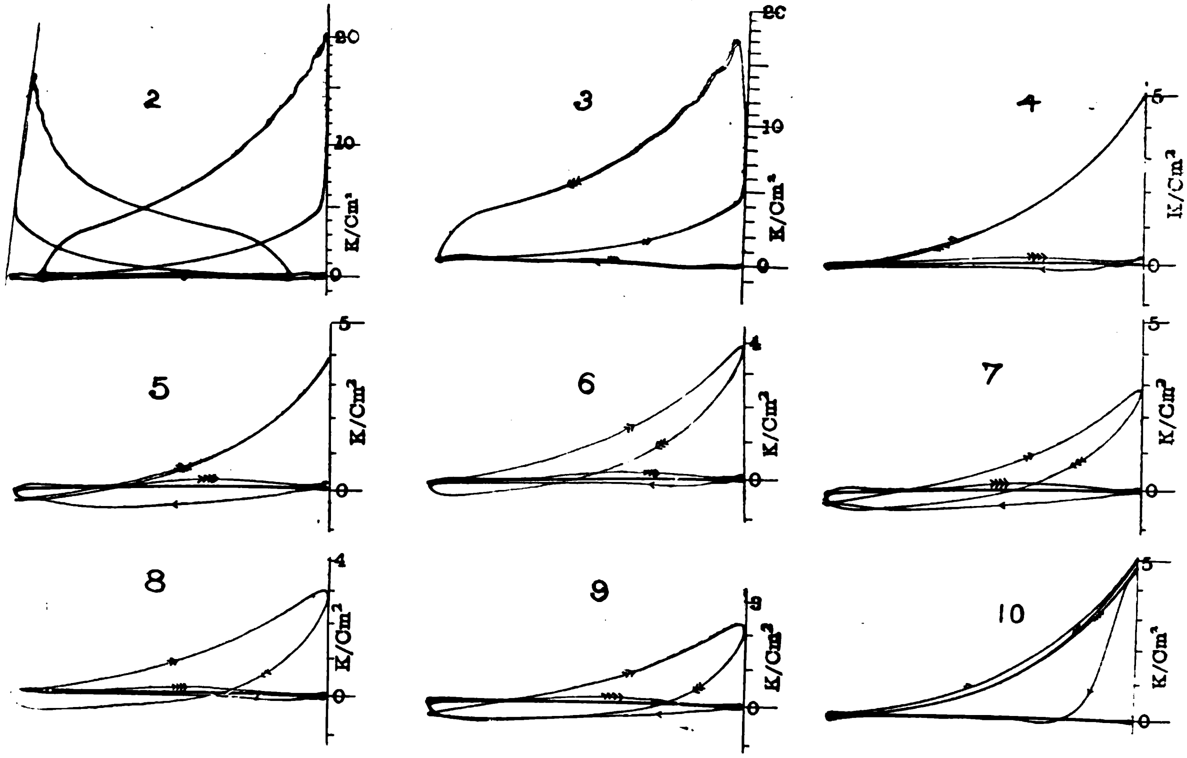
*Abstract of a paper read before the Automobile Club, on Thursday, February 15th, 1906.



Figs. 2 to 10.—Dr. Watson's Manograph Diagrams. (To convert kilogs. per sq. cm. into lbs. per sq. in., multiply by $\frac{128}{9}$.)

cocks half open, the diagram obtained is shown in Fig. 7, and the corresponding powers are given in line 5 of the table.

On opening the compression-cocks to their full extent, which corresponds to a hole ¼ in. in diameter, we obtain Fig. 8 with the throttle open, and Fig. 9 with the throttle closed, the corresponding power being shown in lines 6 and 7 of the table. Here it will be noticed that the indicated horse-power has risen to ·94, the total power required to drive the engine being 1·69 h.p. Experiments were not made with larger orifices, since an examination of the diagrams and numbers showed that no appreciable improvement was likely to be produced.

Before proceeding to discuss the results, attention may be drawn to Fig. 10. This is the indicator diagram obtained when the exhaust-valve is prevented from opening, so that there is now compression on stroke 4, the pressure at the commencement of stroke 1 falling rapidly, owing to the opening of the inlet-valve. There is now a considerable area enclosed between lines 1 and 4, the indicated horse-power being 0·85, which corresponds to 1·60 h.p. required to drive the engine. This power was not directly measured, since the previous measurements had shown that by adding ·75 h.p. to the indicated horse-power we obtain the total power required to drive the engine.

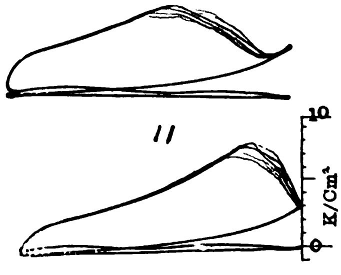


Fig. 11.—"No-load" Diagrams.

If it had been possible to alter the phase of the cam which opens the exhaust-valve, so that in place of opening in stroke 4 it opened in stroke 3, then the indicator diagram obtained would consist of two loops similar to the loop included between strokes Nos. 1 and 4 of Fig. 10. The indicated horse-power would then be 1·65, and the total power required to drive the engine 2·40 h.p. This represents the maximum braking effect which it is possible to obtain with the engine, and we have now to consider what relation these various braking horse-powers bear to the horse-power the engine develops when working. As has already been mentioned, the engine, when working at 700 revs. per min., develops 5·94 i.h.p. This corresponds to 5 i.h.p. at 590 revs. What we require, however, is the brake horse-power. This may be obtained by measuring the indicated horse-power at no load. Since, however, it was found that with no load the diagram was very irregular if both cylinders were allowed to fire, one cylinder was prevented from firing by holding down the corresponding trembler. The diagrams thus obtained are shown in Fig. 11. The speed being 690, the indicated horse-power is 1·52. This corresponds to an indicated horse-power of 1·30 at 590 revs. Since the throttle was almost closed, the conditions under which the engine was running resemble those of line 3 of the table, where the power to run the engine was found to be 1·22 h.p. The agreement is thus seen to be good, and hence we may take the brake horse-power as being 3·7 at 590 revs.

Hence, collecting the results of the experiments, we have :—

	H.P.	Ratio of braking to power.
Power delivered at clutch by the engine when working	3·7 ...	—
Braking effect when throttle is closed ...	1·22 ...	33%
Braking effect when throttle closed and compression cocks open	1·49 ...	40%
Braking effect when exhaust-valve is prevented from opening	1·69 ...	46%
Braking effect when exhaust-valve is opened on No. 3 stroke	2·40 ...	65%

Thus the maximum braking effect which can be obtained at the clutch is 65 per cent. of the power the engine is capable of giving at the clutch. If we were to take into account the losses in the transmission gear between the clutch and the road wheels the percentage of braking effect would be considerably increased, since this loss in transmission would decrease the power delivered by the engine and increase the power absorbed when the engine acts as a brake. Thus, if the loss between the clutch and the road wheels amounted to 15 per cent., the maximum braking effect rises to 88 per cent. of the power the engine is capable of exerting, it being supposed, of course, that the same gear is employed in the two cases.

It will be seen from the above that the engine is capable of being used as a powerful brake, and one which possesses this important advantage over the ordinary brakes in that the water-circulating system will remove the heat generated, and thus prevent the occurrence of burnt brake leathers and such-like.

SOME UNSOLVED PROBLEMS IN MOTOR ENGINEERING.

UNDER the above heading, a very interesting paper was read by Colonel R. E. B. Crompton, C.B., R.E., &c., before the Automobile and Cycle Engineers' Institute, at the Royal United Service Institution last week (February 14th), and in this paper he brought forward a number of vital questions affecting the future prospects of the automobile industry. Many of the points raised were naturally of a somewhat debatable character, and consequently the discussion, which is to be concluded at the next meeting (it is hoped next Wednesday), ought to bring to the front some further useful views from those taking part in it. Col. Crompton clearly showed that he is by no means satisfied with the present practice in motor car construction, and it was also evident, from what he said, that he does not look upon the petrol engine of to-day as being anything like final. Even its relative merits in comparison with steam are, he thinks, grossly exaggerated in the eyes of the motoring public.

In his introductory remarks he pleaded that—although he spoke from the standpoint of a mechanical engineer who had closely studied the subject for over forty years—it was impossible for him to possess as great a knowledge in many matters of detail as those engineers who have given their entire attention to the manufacture of cars during the past few years. He then briefly reiterated the distinctive features of the modern petrol vehicle, remarking that it apparently had settled itself down into a well-defined form with a long low-hung chassis having a wheel base of from 9 to 12 feet, and with comparatively small wheels, shod with 30 to 34-inch rubber tyres. After mentioning the other orthodox characteristics of such vehicles, he expressed his regret that any cars deviating from such design should, irrespective of their merits, be regarded as "freaks." He fully admitted that for touring work, and even for town use, the car of to-day gives most excellent results, but what he did lay special emphasis upon was the fact that the same constructional features, when applied to commercial vehicles and to vans, were far from satisfactory and needed radical modification.

Passing on to give actual instances bearing upon these general observations, he took in sequence matters affecting the engines, the gearing, the wheels with their tyres and springs, as also the proper height of the vehicle above the road surface. In dealing with the engine question, he made an exceptionally strong point—one which is bound to lead to considerable discussion—of the superiority of up-to-date steam systems over the petrol engine, even at the present day.

Petrol Engines.

There were two main respects in which Col. Crompton considered modern petrol engines were defective, one of these being of an essentially radical character, and the other of a far more detailed nature. Mentioning the latter first, since it can be dismissed in a comparatively few words, we refer to his strong advocacy of further development in paraffin carburettors. He pointed out that although it is quite true many existing engines will run on paraffin when once heated, yet there is no really satisfactory vaporiser or equivalent device that renders starting easy with heavier fuels, or subsequent running absolutely successful. The really radical departure which he advocated, and on which he spoke most strongly, was the total abolition of the present "Otto" cycle, and the adoption of some such system as that tried some few years ago by Brayton for simplifying the engine itself and rendering it much more like a steam engine. He pointed out that many difficulties would undoubtedly have to be overcome before this object could be attained, but that the "Brayton" method of obtaining a continuous series of explosions in an independent chamber, and of merely feeding an engine with this elastic fluid under pressure would, from many points of view, be infinitely superior. Col. Crompton, did not, however, enter into any details of a constructional character, or point out the exact nature of the present troubles which would have to be eliminated.

Also, by way of adverse criticism of modern petrol engines, Col. Crompton expressed the views that magnetos, or indeed any electric ignition systems, were almost too far outside the province of the ordinary driver of a motor car to render them altogether desirable, and that, although a multiplicity of cylinders was necessary in order to ensure smooth running, yet the risk of stoppages occurring on the road was necessarily greater, owing to so great an increase in the number of parts, even if the increased cost of pro-

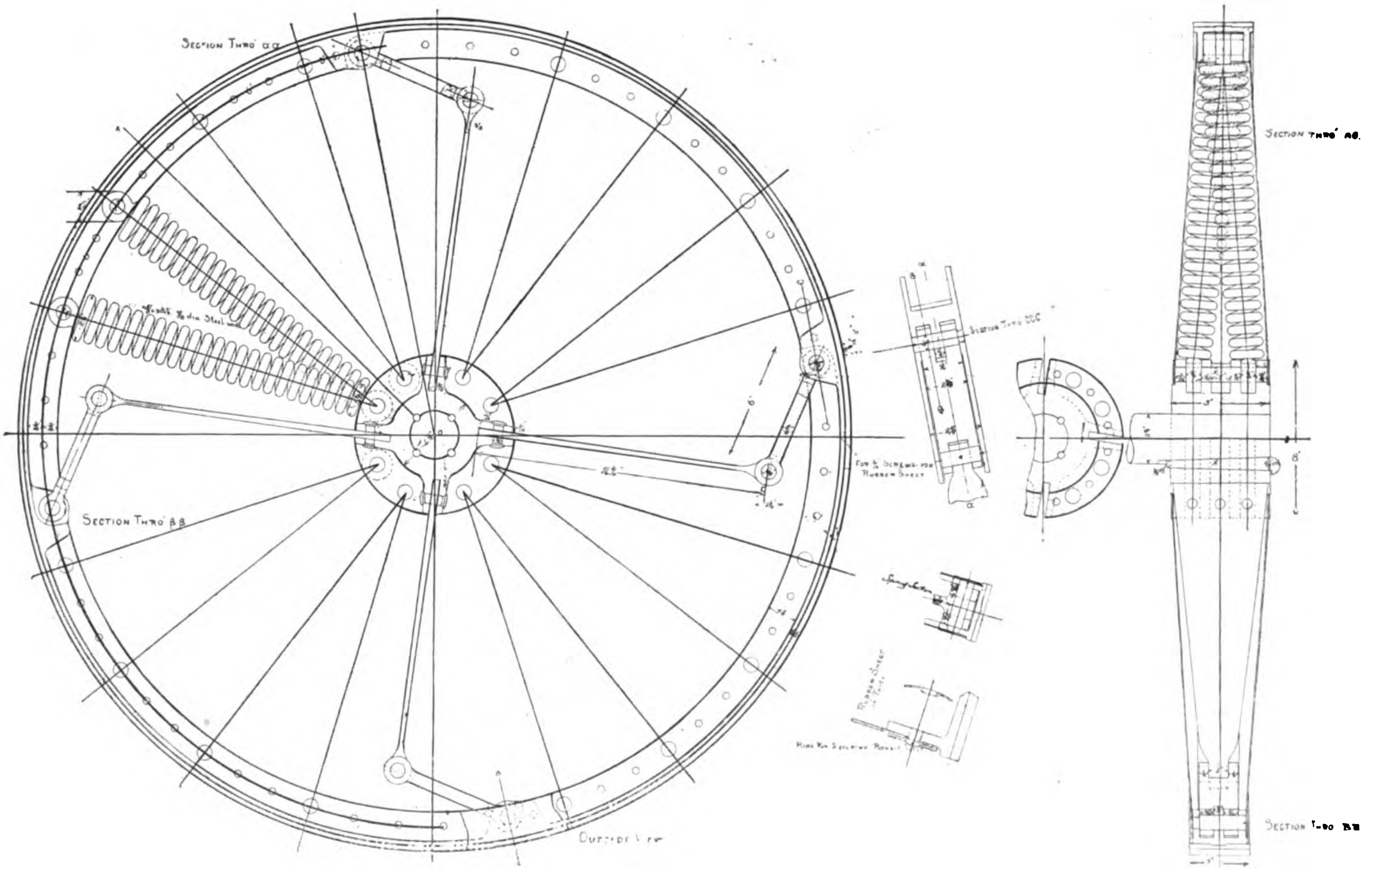

Fig. 1.—Prof. R. H. Smith's "Spring-Wheel," the special feature of which is that the radial springs only serve the purpose of absorbing the shocks, and that separate, linked spokes are fitted for transmitting the "drive" from the hub to the rim.

duction were to be largely compensated by the adoption of improved processes of manufacture.

Steam Engines.

Admitting that at present the petrol engine is in far more general favour for smaller vehicles, and that remarkable improvements have been made in its design and manufacture, Colonel Crompton considered that the introduction of flash and semi-flash boilers had brought about an equally evident improvement in steam systems for the propulsion of the same class of vehicle. He even went so far as to state that the most up-to-date steam cars can quite easily hold their own as regards running cost, as well as in all other respects. In support of this view he gave the following table :—

Comparative Cost Per Annum—on a 5,000 Miles' Basis—of Steam and Petrol Touring Cars.

	Steam Driven.	Petrol Driven.
Steam car, costing £600.	£ *s.* *d.*	£ *s.* *d.*
Depreciation at 15 °/o per annum ...	90 0 0	—
Petrol-driven car, costing £900.		
Depreciation at 15 °/o per annum ...	—	134 0 0
Fuel, on 5,000 miles' basis.		
Steam car, at 14 miles per gallon of paraffin or benzolene at 7½*d.* ...	11 5 0	—
Petrol car, at 20 miles per gallon of petrol at 10*d.*	—	10 10 0
Tyre repairs.		
Steam car, one complete set two-thirds worn out	37 0 0	—
Petrol car, one complete set fully worn out	—	41 0 0
Stores	7 15 0	21 0 0
Other repairs	32 0 0	45 0 0
	£178 0 0	£251 10 0

The figures taken in it are based on the assumption that the initial cost of a large touring car, seating five or six people, and able in addition to carry a fair amount of luggage, is, on the average to-day, 50 per cent. more if it is a petrol car than if it is a steam vehicle. The petrol car is taken at £900 and the steam car at £600, and Col. Crompton expressed the view that some such difference in price as this will always continue to exist, owing to the greater number of parts that are necessary for the petrol car. As will be seen from the table, the chief item which tells so strongly in favour of the steam car is that of depreciation. Colonel Crompton's contention therefore is that the essentially greater prime cost of the petrol vehicle much more than outweighs any gain it may otherwise have in fuel consumption, and that even its greater tyre bill alone does so also. He pointed out that the petrol car must have at least four, if not six cylinders, and that the steam car need only have two.

Speaking further on the relative merits and demerits of steam, he dwelt on the fact that flash generators, as made to-day, need practically no attention, but that, on the other hand, there was a considerable amount of room for improvement in vaporisers and in burners for enabling them to consume heavier and cheaper fuels than petrol or benzoline.

Gearing.

Colonel Crompton's remarks on the question of gearing were more especially applied to vehicles propelled by internal combustion engines than to steam cars, and he commenced by showing that even if the so-called direct-drive were provided for, there were yet necessarily three shafts instead of two, since an extra shaft was required for changing speed and for reversing (with a chain drive it is four shafts that are needed). He was strongly of the opinion that this multiplicity of shafts and of gear-wheels cannot long survive, and this in itself was one of his strongest reasons for holding that the "Otto" cycle would have to give way to a more elastic type of engine.

Even, while still using petrol engines as they are, Col. Crompton holds it to be most important that the transmission gear should be simplified, and that, at any rate, no more than three shafts—the axle, the propeller-shaft, and a combined clutch and reversing mechanism—should be employed. Concerning the gearing itself, he very strongly condemned bevel gearing, since it needs most careful adjustment and perfect workmanship. Instead of bevel wheels, he expressed himself to be an ardent advocate of worm gearing, pointing out that an extremely large contact surface was obtained, and that it was always easy to maintain a true contact surface, even after wear had taken place. In his opinion there was an overwhelming advantage to be gained with worm gear from the point of view that the contact surfaces could be made large enough to prevent the film of oil from being squeezed out from between them as it is with bevel gear.

Col. Crompton very strongly condemned the ordinary type of change-speed-gear now employed, and referred to the very short life of the "second" and "third" speed wheels in particular on the motor 'buses that are now in use. He stated that many of these wheels only lasted for a few months, and he very forcibly condemned the noise and rattle which is already so apparent in the streets from this cause. He was quite convinced, in fact, that all intermediate speeds should be entirely abolished, and he was satisfied—after having gone carefully into the question—that motor omnibuses could be successfully run with no change-speed-gear at all. Naturally, of course, the size of the cylinders would have to be increased in order to enable the engine to start the car on the top gear.

Wheels, Tyres, Springs and Axles.

The comparatively small size of the wheels and tyres of to-day has, the lecturer said, entirely resulted from the introduction of rubber tyres, for not only is the cost of this resilient material considerable, and it is the greater speeds which have been rendered possible by them that have made it advisable to keep the centre of gravity of the vehicle lower. From the point of view of the commercial vehicle, in particular, the cost of upkeep of tyres and wheels is, as he said, a very serious item. He therefore thought that considerable attention should be devoted to the question, and that consequently spring wheels should, if possible, be developed. Most of those which had already been tried are, he held, much too noisy if they have metallic tyres to crush the surface of the roadway, and it might well be found necessary to restrict their speed of travel in consequence. An alternative, however, is to cover the rims with some noiseless resilient material. From his study of spring wheels, it appeared to him that inventors had proceeded along two distinct lines, one of which was, he thought, entirely wrong. He referred to that class of wheel in which an elastic material, such as rubber, is used to give the necessary cushion action, and is merely fitted nearer to the centre of the wheel instead of upon its periphery. He condemned this principle, because its main object was to reduce the amount of rubber, and in consequence to greatly increase the wearing action upon it. Even when using metallic springs instead of rubber, he thought it equally necessary that no attempt should be made to reduce their weight unduly, for it is essential that they should have such a cross-section as would satisfactorily absorb the work put into them.

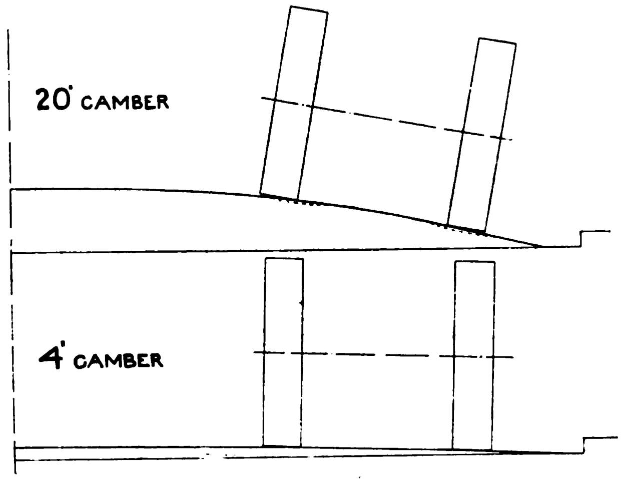

Fig. 2.—Two diagrams indicating the harmless effect of a 4-inch camber on a road 30 feet wide, and the detrimental action of a 20-inch camber both on the road itself and on the wheels and tyres of vehicles.

Several examples of spring wheels were brought before the notice of the meeting, but most of these are already well known in all their bearings by readers of THE AUTOMOTOR JOURNAL. One interesting instance of a wheel of this character was that designed by Professor R. H. Smith, of which we now reproduce a drawing (Fig. 1). In this wheel, the principle has been adopted that it is impossible to get sufficient elasticity from straight radial spokes, that each spoke can, however, be lengthened and thickened in the form of a long spiral, but that such spiral springs must not be used for the double purpose of transmitting the drive and of absorbing shocks. As will be seen, a second set of links is provided for transmitting the power from the hub to the felloe.

One great difficulty experienced by those engaged in the design of spring wheels was very carefully pointed out by Col. Crompton, this being the exaggerated camber in the cross curvature of many of our roadways. He mentioned that a well-made road, 30 ft. wide, ought not to have a total rise at the centre of more than four inches, and that with such roads there was no difficulty in getting a broad tyre to bear evenly all over its surface. He had, however, found many of our London macadam roads of this width with a camber of up to 20 ins., the bulk of the slope being close to the gutter. To show the trying conditions imposed by such road surfaces—as also the detrimental effects on the roadway itself—Col. Crompton brought before the notice of the meeting the diagrams reproduced in Fig. 2—these being, we think, self-explanatory. Designers of road wheels have at present this great difficulty to contend with, and Col. Crompton expressed the view that the excessive and irregular camber referred to is undoubtedly one of the chief causes of the deterioration and heavy wear of pneumatic tyres also. He thought it spoke extremely well for the inventive talent and constructive merits of the pneumatics of to-day that they could stand the severe strains imposed upon them from this cause as well as they do in practice. He urged combined action on the part of road authorities and car manufacturers, so that everything that it was possible to do should be done to minimise wear and tear of tyres and of roads alike. Spring wheels, in particular, were apt to suffer seriously, particularly those which have sliding devices near the rim for allowing a relative motion between the axle and the tyre. On the general question of the suspension of pleasure vehicles, Col. Crompton thought that the only error that had been made of late had resulted from attempting to reduce the weight of the springs unduly, for otherwise the springing of such vehicles was luxurious. In particular he commended the recently introduced three-point suspension with a transverse spring at the back.

Dustlessness.

In concluding his paper, Col. Crompton referred at some length to the important experiments which have been conducted over a long period by the Automobile Club, with the object of ascertaining the best means of reducing the dust nuisance. He stated that it had been shown to be most important to keep the under surface of the vehicle well above the road, and to so shape that surface that air currents at the back were avoided. The under surface of a car should take the form of the lower half of a fish, with a comparatively blunt nose but a fine stern. Another matter of importance was the provision of adjustable flaps on the front mudguards, so that these could be raised higher from the ground in dusty weather, and only let down in muddy weather. Col. Crompton also thought that better results would be obtained by using wheels of larger diameter, and by raising the car higher from the ground; and he pointed out in this connection that the tyres themselves would benefit considerably by so doing. In his opinion, tyres of larger diameter, with a less cross section, used in conjunction with wheels of improved design—possibly spring wheels—would ultimately be found best of all.

* * * *

Evils and Dangers of Motor 'Bus Racing.

THE evils and dangers of motor 'bus racing, to which we again draw attention editorially this week, have been emphasised by two instances, the reports of which in the daily Press effectively prove that we have not been denouncing a merely imaginary evil. They fortunately prove at the same time that the police are disposed to do their duty in the matter. We refer to the two instances in which the drivers of motor omnibuses were summoned before Mr. Plowden for exceeding the legal speed. The pace at which the omnibuses travelled was, according to the defending solicitor, limited by the governor, which prevented the 'bus exceeding the legal limit of 12 miles an hour, in the usual way, by cutting off the supply of explosive mixture when that speed was reached. Mr. Plowden observed that if this were really the case it would be a very important matter for the police, as they need never, in that case, summon omnibus drivers for exceeding the speed limit. At the same time he would like to see the apparatus in question thoroughly tested, and he adjourned the summonses in order that this might be done, and the question decided once for all, whether a motor 'bus could or could not proceed above the legal limit. In the other instance, a telephone worker, surrounded by the usual flimsy shelter, had been run into and seriously injured by a motor 'bus, the result ultimately being a coroner's inquest, in which one witness stated that, in his opinion, the motor 'buses had been racing along the Marylebone Road. This is exactly the sort of thing that we have complained of as a serious public danger. It is, in fact, as we have repeatedly declared, a much more serious danger than was possible when similar proceedings took place with the old horse-drawn 'buses. It is dangerous to the public, dangerous to the drivers, in fact, dangerous to everybody, and, after all, it only results from an unfair attempt to interfere with fair and open competition.

Still later, an even worse example of the results of motor 'bus racing has occurred near Baker Street Station. There was an actual collision between a "Vanguard" and a "General," the sort of thing that occurred of course often enough during the late Russo-Japanese War, but one which one must admit is undesirable in the heart of a city at peace with all the world. Fortunately, little damage was done, only one lady being slightly injured. But no one can really say what damage the same spirit, if allowed to run riot, may not produce at an early date. The principle involved does not in any case recommend itself to a sense of fairness. Why should the pioneers of the new method of locomotion—a new method of catering for the public—be "run off the roads" by an older organisation which, if left to itself, would, as far as can be judged, have introduced the motor 'bus about the time of the Millennium, if at all?

We repeat that we are glad the police have taken action in the matter. But after all, the little comedy which took place before Mr. Plowden has really nothing to do with the main question. Where 'bus competition results in racing, it is the reckless spirit engendered which is far more dangerous than the actual pace attained. A motor 'bus can be dangerous enough at 12 miles an hour, unless it is piloted by a cool-headed driver, whose only consideration is the safety of his vehicle and passengers. If he once gives way to the racing instinct and attempts to get to an important point before his rival, then danger in its most serious form is introduced into the situation. We would suggest, therefore, that instead of prosecuting the offenders for exceeding the speed limit, the police should proceed under Section I. of the Act, "to the danger of the public."

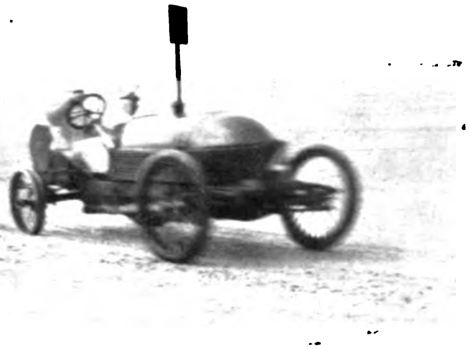
Renewal of Licences.

THERE has been an amusing passage of arms (by correspondence) between Earl Russell and the West Sussex County Council. On making application for renewal of his licence, the Clerk to this body asked for the previous licence to be forwarded to him. Lord Russell pointed out in reply that this was an illegal demand, and that the Clerk had no power to ask for it. This, ultimately, was admitted by the Clerk. Lord Russell pointed out that the Council official by withholding his licence had exposed him to the risk of prosecution for five days. The whole thing is a commentary on the preposterously muddled state in which questions of this kind have been left by the Act.

RACES, RECORDS, AND TRIALS.

Ormond - Daytona Races '06.

The Napier making the last turn in the Record 100 Ormond. 24/1/06. going 80 M.P.h. upon 3 tyres.



Ryan

65 MILES RACING ON THREE TYRES.—It has been regarded in many quarters as almost impossible that a racing car, like the 6-cylinder Napier, could be driven for 65 miles on the sand with one tyre missing, and that the car should not only under those circumstances, win the race, but put up a new time record for the 100 miles. That Earp *did* accomplish this feat, on Ormond-Daytona Beach, however, is quite certain, and we are able this week to supplement the photograph of Earp and his car without the tyre, which appeared in the last issue of the "Automotor Journal," by the one above taken of the Napier at full speed rounding one of the many turns. In this view, it will be clearly seen that the off-side rear tyre is missing.

A.C.G.B.I. Tyre, Speedometer, and Lamp Trials.

IN spite of the very meagre list of entries for the A.C.G.B.I. Tyre Trials, we understand that these will be proceeded with, and thus afford bold advertisement to the two firms who have taken their chances under the auspices of the club.

In fact, these will be started on March 1st instead of Feb. 26th, as before arranged. The Wolseley Garage at Niagara has been placed at the service of the A.C.G.B.I. for these trials, and it is there where the cars engaged in the event will be placed each night, until the completion of the tests over the full 4,000 miles. The cars, upon which the entered tyres and devices will be fitted, are a 20-h.p. Dennis (also officially entered for endurance), a 20-h.p. Rolls-Royce, and a 28-h.p. Daimler. All these will be fitted with Collier tyres, two with the standard pattern, and the other with an experimental set with beaded edges. The Hartridge solid tyre set entered will be tried on a Leyland-Crossley omnibus, whilst a steam lurry may also be found "in the running." The nine speedometers entered, seven of which are arranged for right-hand wheels, will be distributed over the cars and 'bus, two of the devices being run probably for 2,000 miles only, each, a course necessitated by the lack of vehicles upon which to fix them. Six different routes will be traversed in rotation by the cars until the full distance is completed. These are: 1, through Oxford to North Leach and return, 165 miles; 2, to Dunchurch, viâ Holyhead Road, and return, 163 miles; 3, Peterborough and return, viâ North Road, 166 miles; 4, Berkhamsted to Banbury, down Sunrising Hill to point 7 miles from Stratford and return, 168½ miles; 5, through Marlborough to a point 4 miles further on the Bath Road, 157 miles; 6, along Exeter Road, through Egham and Basingstoke to Stonehenge, and return, 158½ miles. A shorter daily run will be arranged for the omnibus.

Circuit Européen.

A CONFERENCE is called in Paris for to-morrow (Sunday, February 25th) of the foreign club delegates to consider several matters of importance in regard to the regulations. Not the least important will be the desire in several quarters to suppress the carrying of "observers" by each car throughout the run—which, if passed, will unquestionably detract very greatly from the value of the tour as a guarantee to the public that all mishaps and causes of delay have been faithfully chronicled day by day.

A Millionaires' Race.

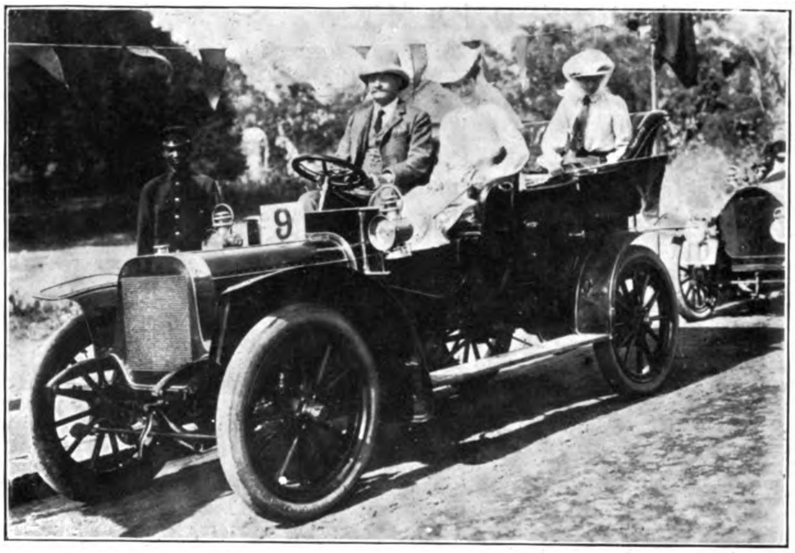
As a side attraction to the Havana long distance race, which we recorded last week, and in which Demogeot, on his Darracq, was the only "survivor," a "sporting event" for tourist cars was arranged to take place at the same time on the course, but only over a distance of 175 kiloms. This was for a pool of 15,000 dollars, between Julio Rabel, J. Aguilles, and Louis Marx, three millionaires, who finished as follows:—(1) Rabel (30-h.p. Bayard-Clement), 2h. 4m. 52s.; (2) Aguilles (30-h.p. Mors), 2h. 5m. 31s.; (3) Marx (40-h.p. Mercedes), 2h. 14m. 2s.

Gothenburg to Stockholm.

UNDER the auspices of the A.C. of Sweden, a competitive run was last week completed between Gothenburg and Stockholm. Seven starters were sent off on Feb. 15th at 7 a.m., as follows:—Bagge (7-h.p. Star), Salmson (24-h.p. Fiat), C. Skamberg (24-h.p. Cottereau), Grebst (12-h.p. Darracq), H. Dahn (12-h.p. Darracq), H. Pripp (12-h.p. Darracq), Petersen (7-h.p. Oldsmobile). The 24-h.p. Fiat was the first in, arriving in Stockholm at 9.46 a.m. on Feb. 16th, making a time of 26h. 46m. for 500 kilometres.

Competition of "Odotachymetres."

THIS is not a race for elephants or tapirs, as might have been suggested by the name to Mrs. Malaprop or her descendants, but refers to a competition of speed indicators, to which the A.C.F., in its wisdom, has assigned the above terrible appellation. Presumably, it is derived from two Greek words—most things that nobody can pronounce usually are—ὁδὸς and ταχὺς (road and swift), and might be translated "swift-road counters." The complete incomprehensibility of the title to anyone not acquainted with the language of Demosthenes is a further confirmation, if any were needed, of the schoolboy's theory that Greek was invented by schoolmasters to provide excuses for application of the rod. In addition, the word ought, on philological principles, to have been "odotachometer," from τάχος, swiftness. There will be prizes awarded in connection with the competition, the first prize going to the machine that combines capacity for showing the speed reached with a record of kilometres traversed. This prize has been offered by Baron Henri de Rothschild, and the Technical Committee of the A.C.F. has been engaged in elaborating a set of rules for regulating the competition. It is the same committee (among whose qualifications for testing speed-counters are said to be a knowledge of Greek) who have elaborated the above expressive, though scarcely euphemistic, denomination for the machine. The gentleman who wishes to stick to French roots for the word has, however, not done much better than the Hellenists implicated, for he puts forward "cheminovitessometre," which, by interpretation, signifieth (literally) "road-speed measurer," and has nothing to do with "chemises," as the unwary might be disposed to opine. After all, the English term has something to recommend it. The name actually adopted suffers, at any rate, from the objection that it might just as well mean a "quick road measurer" as a road and speed indicator, but such things are trifles to philologists and word-makers when they have got their spectacles on and their dictionaries in full swing.



Amongst the winners in the Motor Union of Western India Reliability Trial, of which a report appeared recently in the "Automotor Journal," was Dr. A. H. Deane's 16-20-h.p. Argyll car, which he drove himself, securing the Trophy Shield in Class C (cars costing from £400 to £600). Our photograph shows Dr. Deane at the wheel of his winning car.

The "Odotachymetre" Trial Rules.

RULES governing these French trials of speedometers and recorders have now been drawn up by the A.C. de France for the Academie des Sports. These provide that the contest shall commence on May 1st, entries at 50 francs to close on April 15th. Subject to less than three entries being received, the trials to be postponed. Competitors must provide cars with the devices attached. The judges will take into consideration—(1) the accuracy of record, (2) the ease of fixing, (3) the regularity of working and strength of the parts, (4) the weight and price.

The trial will consist of two tests, viz., (a) running twice on the Montgeron-Ozoir-la-Ferriere road, a distance of 100 kiloms., during which independent readings will be taken every 25 kiloms.; (b) a bench test in the laboratory.

Vienna to Gratz.

THE Austrian Automobile Club has arranged a reliability trial for light touring cars for the 12th and 13th of May, from Vienna to Gratz and back again, forming a total distance of 410 kiloms. The trial is confined to cars of a standard type driven by internal combustion engines. Single-cylinder motors are limited to a capacity of 1½ litres, 2-cylinder motors being allowed 2·5 litres capacity.

* * * *

The Agricultural Motor for Essex.

AT a recent meeting of her Essex tenants at Dunmow, the Countess of Warwick made some drastic remarks on the preferential treatment accorded to foreigners by British railway companies, and the result which it had produced of rendering profitable farming in the home counties difficult, if not impossible. The Countess recommended that the system she had adopted at her agricultural college at Studleigh, near Birmingham, of organising a motor transport service, should be employed in Essex, a proposal which was also supported by Mr. James Hewson. He, however, goes a step further, and proposes that the farmers should organise a motor transport service themselves, and that the service should consist, not merely of motor vehicles for carrying the produce, but of motor-propelled stalls for displaying the same for sale. The general adoption of systems of this kind would, in his opinion, soon bring all the "waste land" in England under cultivation.

The Automobile Export Trade of France.

STUPENDOUS are the figures which represent the *export* of automobiles and parts from France. For 1906 the figures are over 100,250,000 francs! As showing where they go to, the *imports* of automobiles and parts into Great Britain for the same period represent no less than £3,446,886 = 86,172,150 francs! The British *exports*, by way of contrast, total up to the comparative bagatelle of £544,028, or only a little more than the odd thousands in excess of the millions of imports. The export figures of France from 1897, when they were first issued separately, are given below, and show the remarkable progress made and the increasing expansion of France's trade in automobiles :—

		Francs.			Francs.
1897	...	623,690	1902	...	30,219,380
1898	...	1,749,350	1903	...	50,837,140
1899	...	4,259,330	1904	...	71,035,000
1900	...	6,617,000	1905	...	100,265,000
1901	...	15,782,000			

CORRESPONDENCE.

THE IMPORTERS' PROTECTION ASSOCIATION, LIMITED.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I enclose a copy of a circular which is being sent to all the firms who are engaged in importing cars or accessories into this country.

The letter will explain itself, and I shall be glad to send particulars and form of application for membership on receipt of a letter to the address below.

I may say that the objects of the Association are in no way antagonistic to that of the Society of Motor Manufacturers and Traders, it being rather the policy of the Association to work in harmony with the Society. The Council of the Association includes several gentlemen who are members of the Committee of Management of the Society who have agreed to receive a deputation from the importers.

It is necessary, however, for the importers to combine in order to protect their interests. The British manufacturers have their Alliance, and the above Association will be recognised as the official organisation of the importers.

Yours faithfully,
H. B. COOK,
Secretary.

483, Oxford Street, W.
February 19th.

Excerpt from Letter enclosed :—

"The Importers' Protection Association, Limited, has been formed for the purpose of protecting the interests of importers of foreign motor cars and accessories, in order that, by combination and concerted action, importers in the motor trade may safeguard their interests and secure for themselves fair and just treatment in matters connected with the motor industry. It is felt that the formation of such an association is very necessary in consequence of the hostile and aggressive attitude adopted by the British Empire Motor Trades' Alliance towards the interests of importers of motor cars and accessories into this country, and the following firms have joined the Association and are represented on the council :—

Council of the Importers' Protection Association.

Firms.	Represented by
A. Darracq and Co., Ltd.	A. Rawlinson, Chairman.
Panhard and Levassor	W. Du Cros } Vice-Chairmen.
F.I.A.T. Motors, Ltd.	D'Arcy Baker
De Dion-Bouton, Ltd.	J. W. Stocks.
De Dietrich and Co., Ltd.	W. M. Letts.
A. Vedrine and Co., Ltd.	Chas. Jarrott.
Du Cros-Mercedes, Ltd.	Harvey Du Cros, jun.
Renault Frères, Ltd.	P. L. H. Dodson.
Mors, Ltd.	Cecil Banbury.
W. and G. Du Cros	Geo. Du Cros.
London and Parisian Motor Company, Ltd. (Hotchkiss).	B. D. Corbet.
Mann and Overton, Ltd. (Richard-Brasier).	J. Overton.
Minerva Motors, Ltd.	D. Citroen.
Donne and Willans, Ltd. (Rochet-Schneider)	Morgan Donne.
Germain Motor Company	Theo Masui.
Clement Motor Company, Ltd.	E. H. Lancaster.
Cannstatt Automobile Supply Association.	J. Clerk.
Gladiator Motor Company	A. McCormack.
Friswell, Ltd. (Peugeot)	C. Friswell.
London Motor Garage Company, Ltd. (C.G.V.).	Claud Watney.
Chenard-Walcker Motors, Ltd.	G. Oakey.
Fabry Automobile Company, Ltd. (Itala).	Maurice Fabry.
British Automobile Commercial Syndicate (Spyker).	Lord Shrewsbury.

Secretary and Office, pro tem : H. B. COOK, 483, Oxford Street, W.

Solicitors : KENNETH BROWN AND CO., 11, Pancras Lane, E.C.

You will realise from this list that the principal importers have already combined to protect the common interest of the motor importing trade, and I am instructed to ask whether you will join the Association and so identify your interests with those of the other importers, as it is felt that the moment is at hand when definite and concerted action may become necessary. You will appreciate that the effect of such action must be directly proportionate to the completeness of the identification of the interests of importing firms.

The Association is incorporated under the Companies' Acts, and is limited by guarantee, each member being liable in the event of the Association being wound up during the time he is a member or within one year afterwards to contribute a sum not exceeding £1.

The constitution of the Association admits of honorary members (for whom no special qualification is required) and ordinary members, the qualification for ordinary membership being the carrying on or being engaged in the business of importing motor cars or accessories as a principal."

AN HISTORICAL CAR.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I have been applied to frequently for an illustration or photograph of the first motor car (internal combustion engine) built in Great Britain, without being able to comply with the request (since I had only one photograph of this car, and the only copy of this was hanging on the wall of one of the rooms of the A.C.G.B.I.). I have now made arrangements with the Autotype Company, of 74, New Oxford Street, to reproduce this photograph in their inimitable manner. I shall be glad to present one mounted and framed copy to automobile clubs, and will forward the picture, carefully packed and free of charge, on receipt of a request from the secretary or other official of the club. The only proviso I make is that the picture be hung in a clearly-visible place in the main room, and not placed anywhere out of sight.

If any well-known hotel or garage on the club list, or even a private individual, wishes to possess a mounted and framed copy of this photo, I shall be glad to forward the picture at cost price, or the photo mounted without the frame.

I have to express to those who have applied to me for an illustration of the first motor boat built in this country my regrets that I have no photograph now of this boat. This was built in 1891 (four years earlier than the car), was running on the river between Richmond and Wandsworth during the winter 1891–2, and was licensed in February 1892, so that it is most probable that some illustration of it would have appeared in some technical journal of the time.

Yours faithfully,
J. D. ROOTS.

Thanet House, Temple Bar.
Feb. 14th.

SIX-CYLINDER AND FOUR-CYLINDER CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I was very interested in reading the letter signed by Mr. Edge which appeared in your issue of the 17th inst. on "An Expert's Opinion on 6-cylinder Motors," and think the way in which Mr. Edge has worked in Herr Maybach's remarks is very clever. When I read the article, all that I understood Herr Maybach to say was that the 6-cylinder car was a good one for racing purposes, and I extract the following from Mr. Edge's letter :—"As he (Herr Maybach) says, 'I can only recognise the justification of the 6-cylinder motor in one case. When the driver wants to get along quickly, when he has to keep his hands on the wheel, when he has not time to change gears, or when a wrong manœuvre with the speed-lever might mean costly seconds, then the six cylinders, where the play with the throttle and advanced ignition permits of every speed variation, is fully justified.'"

I leave it to the readers of your paper to say whether this is wanted in a touring car, or whether it does not describe exactly what is wanted in a racing car. I think everyone agrees that a 6-cylinder car for a race has its advantages, and probably an 8-cylinder is better still, as has lately been demonstrated by the Darracq at Florida, and I think it is probable we shall see 6 and 8-cylinder racing cars this season. It must be admitted that the performance of the 8-cylinder Darracq at Florida means that it has beaten the 6-cylinder car, and if that is so why stop at six—why not have eight cylinders, or even twelve?

If I remember rightly, Captain Deasy, in a very sportsmanlike way, said that he was of an open mind as to whether a 4- or 6-cylinder was the better car of the two, and for this reason he would be glad to put his 4-cylinder car against a 6-cylinder. Mr. Edge immediately came forward and offered to put his 6-*cylinder racing car* in competition, to which Capt. Deasy naturally objected, as he wanted an ordinary touring 6-cylinder. Now, what I am anxious to see, and what I think the public at large are anxious to see, is the ordinary 6-cylinder touring car in open competition against the ordinary 4-cylinder touring car of the same horse-power and same cylinder capacity. All these marvellous letters on the 6-cylinder car mean nothing; let us see the actual 6-cylinder touring car in open competition with the 4-cylinder touring car—whether they are foreign or English, matters little.

If Mr. Edge would like to have expert opinions on the 6 cylinder motor I should say that the representative of the Mercedes would be happy to obtain Herr Maybach's full opinion, and if the constructors who are responsible for the designing of such cars as the Panhard, Charron, Renault, Richard-Brasier, De Dietrich, Daimler, Argyll, and Napier were to write their opinions upon the subject, I think it would be very interesting reading—far more so than the letters which have been appearing lately on this matter.

Yours faithfully,

February 19th. W. M. LETTS.

BRITISH CARS FOR CANADA.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I have been asked by the A.C.G.B.I. to read a paper before them on March 1st (Thursday), entitled "Motor Trade with Canada."

They have asked me to do this because the first motor exhibitions in Canada are soon to be held: one in Toronto, March 31st to April 7th, and one in Montreal, April 21st to April 28th.

I have been requested by the Canadian people interested in these shows to point out the opportunities for opening up a trade in Canada for British cars. Acting as Commissioner for the British manufacturers, I expect to sail with the cars from Liverpool on the "Lake Manitoba," Tuesday, March 13th.

Briefly, the reasons why a good trade with Canada can be opened up in motor cars are these:—

First: About 3,000 American cars have been sold in Canada last year, and are giving so much trouble to their present owners that they are desirous of getting rid of them and want to "go in for motoring." The British cars will suit them, and are admitted into the Canadian market at a third less tariff than those of any other country, including the United States. As the duty is 35 per cent., this is, roughly speaking, a preference of 12 per cent. in favour of British cars.

Second: The great and increasing prosperity of Canada makes Canadians want good motor cars, and enables them to pay for them.

The British cars for these shows will be admitted duty free, and the duty need not be paid unless the cars are sold.

I am assured, however, that the cars will be sold, as people from all over Canada will attend these shows, and will be anxious to take up agencies for the sale of them in the future.

I hope that you will give the wide publicity to these facts which a journal of your great circulation can do, and thereby assist the manufacturers of British motor cars to grasp the right hand of fellowship that Canada is holding forth to them in her preferential tariff.

Further information to those interested, and entry forms will be furnished on application to me, at 272, Birkbeck Chambers, Holborn, W.C.

Faithfully yours,

February 19th, 1906. E. H. TURNBULL.

THE FLYING PROBLEM.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Perhaps I did not make myself quite clear, as Mr. Roe appears to have been doubtful as to the construction to be placed on a portion of my letter.

My contention is that the aeroplane, even when fitted with a propeller, is too erratic and uncontrollable to ever become a satisfactory and safe means of aerial navigation. It requires some other device or mechanism to render it more dirigible and controllable.

The reasons for this are as follows:—

1. Assuming that an aeroplane were aloft, loaded with passengers, and travelling at, say, 20 miles an hour, and that there were no wind or only a light one of, say, 5 miles an hour, and something happened to the engine or the propeller-shaft, the chances of the machine or the passengers reaching earth safely would be remote indeed.

2. A car on wheels, or something the equivalent of it, is necessary to permit the aeroplane to start, and a considerable length of run would be necessary in a machine of larger size, as it requires a wind of 18 miles an hour to lift the aeroplane. A wind of 18 miles an hour in perfectly open country might suddenly drop to five in places sheltered by houses and trees.

3. The aeroplane necessarily requires considerable space in which to start and alight, as in order to effect these operations easily it must travel in a line only a few degrees from the horizontal, and with buildings in the neighbourhood the machine might, while moving slowly, suddenly encounter a deflected or cross current and capsize.

4. In a gusty wind the aeroplane, as I have found from my own models, is very erratically inclined. It may on six consecutive occasions glide perfectly smoothly and in accordance with expectations, and on the seventh either glide directly for the earth, or it may in a gusty wind or if it meets a cross current behave like a piece of paper in the wind or a tumbling pigeon. Without placing too much reliance on results obtained with models, I think that to give a certain degree of safety (complete safety can only come through the process known as "trial and error" in the air), some direct lifting mechanism is necessary, as also something in the nature of a parachute to prevent a too rapid descent in case of any failure of the engine or propeller-shaft.

I quite agree with Mr. Roe that it is possible to fit a vane to an aeroplane which should act in a somewhat similar manner to a downwardly-turned bird's tail for arresting forward motion, but for the reasons before given I do not think there can be the necessary degree of control and dirigibility to render the aeroplane alone a safe working aerial machine. The aeroplane requires the addition of some device giving a more direct and definite control.

Yours faithfully,

February 19th. J. D. ROOTS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In answer to Mica Cam's letter, my model illustrated is to scale, and is one-twelfth the size of the Wrights' latest machine, but only has 145th of the surface area, and consequently the weight should be 145 times less, which it easily comes under, namely, three-quarters of a pound.

I understand the Wrights' latest machine had eight vertical struts, two propellers with a rudder at the back of each, the engine and weight being on a plane above the lower, and much below the upper carrying surface. They found by carrying the weight below this point, that is below the centre of gravity, there was a tendency for the machine to wobble.

Mica Cam points out that the model illustrated, if made full size, would lose one of the Wrights' distinctive features, namely, reduction of friction, but I fail to see why this should be so, for when making full size one would naturally arrange all the struts, &c., as fine as possible. In the model shown the struts are of sharp oval section in order to offer as little resistance to the wind as possible.

However, this summer should witness some interesting experiments with full size machines, then all these points can be thoroughly gone into in a practical way.

Yours faithfully,

A. V. ROE.

The Trophy Shield Secured by Mr. Deane with his Argyll Car, in Class C, of the Indian Motor Union Reliability Trial.

CLUBS AND ASSOCIATIONS.

Aero Club.

THE following have been elected to the New Meteorological Committee of the Club:—Sir Norman Lockyer, the Hon. C. S. Rolls, Professor Huntington, Mr. Roger Wallace, Mr. Pollock, Mr. Dines, F.R.S., Mr. Alexander. This committee has arranged to work in conjunction with the Royal Meteorological Society, with a view to carrying on a series of balloon ascents for the purpose of the scientific research of the higher atmosphere by means of observations and experiments and continuous, in fact, with the work done by the late Mr. Jas. Glaisher, F.R.S., in Coxwell's balloon in the latter part of the last century. The Technical Committee of the Aero Club, whose principal functions are the investigation of aeroplanes and flying machines of the heavier-than-air type, has been constituted for 1906, as follows:—Sir Hiram Maxim, the Hon. C. S. Rolls, Sir H. E. Colville, Major Baden-Powell, Colonel J. E. Capper, Mr. Frost, Mr. Pollock, Mr. Alexander, Mr. Spencer, Mr. Sims, Mr. Wallace, K.C., Mr. Moore-Brabazon, Dr. Hutchinson, Professor Huntington. Some interesting competitions in connection with this important branch of aeronautics are to be organised by this committee.

Automobile Association.

A MEETING of the association has been arranged to be held on March 26th at 4 p.m., at Cordingley's Motor Car Exhibition at the Agricultural Hall. *All* interested in motoring are invited to attend.

British Empire Motor Trades Alliance, Limited.

THE Dunlop Pneumatic Tyre Company, Limited, have promised a donation of twenty guineas to the Alliance's Foundation Fund. The following firms have recently been elected to membership:—Horsfall and Bickham, North British Rubber Company, Limited, Edwin Richards and Sons, Rover Company, Limited, Laurie and Marner, Limited, Willans and Robinson, Limited.

British Motor Boat Club.

THE annual general meeting of this club, we are informed, will be held on Tuesday, Feb. 27th, in the Club Room, Craven Hotel, Charing Cross, W.C., at 5 p.m., instead of on the 23rd as previously announced.

The club held at its headquarters, Craven Hotel, Charing Cross, last week, an Informal Dinner, after which Lieut. Windham, R.N., read a Paper on the "Practical Handling of Motor Boats," which he illustrated with lantern slides, some of which showed his work in connection with the lifeboats on the West Coast of Ireland, and elsewhere.

Lieut. Windham opened his lecture by pointing out the absolute necessity for some practical nautical knowledge on the part of those handling motor boats, and feared that unless motor boating was taken up in a somewhat more serious manner than motoring is to-day, thrilling accidents would happen.

The form of petrol engine best fitted for motor boat requirements was then dealt with. To ensure each piston getting its proper amount of lubrication, the crank-chamber should be divided into two if not four sections, to prevent the oil in the crank-chamber from flooding one cylinder, fouling plugs, and stopping the engine. Marine motors require more lubrication than those on cars. Special provisions are also required for the water circulation, for the reason that no radiators are required. Pumps should be used, slow running for preference, but not working on the principle of those fitted to cars. In fitting them, means have to be provided for preventing the choking of the grating leading to the water pipes, by seaweed.

Petrol tanks must have larger capacity than those on cars, and as head-winds and head-seas may delay the boat, spare tins of petrol must always be carried. Leakages in the fuel-feed piping should be strictly guarded against. The clutch and fly-wheel should be heavier than those fitted in cars—the momentum of the road-wheels of a car being absent. A low-tension magneto is preferable to accumulators, but every boat should have two independent sources of ignition.

With regard to the propeller, the number of blades is of great importance. Lieut. Windham preferred two blades, but three were easier to balance. Phosphor-bronze is preferable to steel.

For the hull, wood is far preferable to steel, for not only is the latter liable to leak, but it is more difficult to keep clean.

Climatic conditions must be studied in ordering motor boats, and reverting to the engine, the sparking plugs must be capable of being removed while the engine is running. Floor boards should be covered with non-slipping material, and every boat should carry an anchor, a cable for hauling and towing, and a sea anchor. He had not had happy experiences with paraffin carburettors.

Seamanship was a very desirable accomplishment for a motor boat owner, in order that he could know how to pass other boats. After giving information on this point, the necessity for knowing how to read a chart was dwelt upon.

Other heads of the lecture were devoted to steering, the necessity for carrying a compass, the kind of compass to use, and how to find the error of deviation in compasses.

How to run in broken water was another subject dealt with in detail by Lieut. Windham, who observed that every motor boat owner ought to go to the trouble of learning a few things connected with the sea.

After Lieut. Windham had concluded his paper and shown various other slides, Mr. Arthur Evans (who was in charge of Napier Major on her long trip last year) exhibited a number of his slides, showing racing motor boats and the historical aspect of the motor boat movement.

Lincolnshire A.C.

AT the annual general meeting of the club, when the president, Sir Hickman Bacon, Bart, occupied the chair, the membership was announced to be 170, and the accounts proved to be in a satisfactory condition. The resignation of Dr. Cragg, the indefatigable hon. secretary, was announced, and accepted with much regret, but it was recognised that, owing to Dr. Cragg's increasing practice, and the heavy work of the club, it was impossible for him to carry on the duties any longer.

The officers of the club were elected as follows:—

President: Sir Hickman Bacon, Bart.

Vice-Presidents: Right Hon. Earl Brownlow, Lord Willoughby de Eresby, M.P.; Mr. W. Garfit, J.P.; Mr. Eric Chaplin; Captain J. A. Cole, J.P.; Mr. M. R. Waldo Sibthorp, J.P.; Mr. C. J. E. Parker, J.P.; Mr. C. W. Pennell, J.P.; Colonel Ruston, J.P.; and Mr. J. D. Sandars, D.L., J.P.

Committee: Mr. A. A. Padley, Mr. W. R. Pennell, Dr. Gilpin, Mr. G. Godson, Dr. Miller, Captain Gleed, Dr. Cragg, Captain Newsum, Mr. W. B. Jevons, Dr. Mason, Mr. W. A. Tomlinson, and Mr. R. Fowler.

Hon. Solicitor: Mr. C. Nelson. *Hon. Secretary:* Mr. Godfrey Lowe, St. Catherine's, Lincoln.

Manchester A.C.

THE annual dinner of the club will be held at the Midland Hotel, Manchester, on March 10th. The following gentlemen have already promised to be guests of the club on that occasion:—The Lord Mayor of Manchester, the Mayor of Salford, His Honour Vice-Chancellor Leigh-Clare, and Mr. C. A. Cripps, K.C.

Scottish A.C. (Western Section).

AN enthusiastic gathering of the members of this club took place on Monday night in the Grosvenor Restaurant, Glasgow, the occasion combining the annual dinner of the club and a complimentary banquet to the Right Hon. Sir J. H. A. Macdonald, K.C.B., Lord Chief Justice Clerk of Scotland, in recognition of his services as President of the club. The chair was occupied by the Right Hon. Sir Herbert Maxwell, Bart.; Mr. John Adam, the chairman of the Western Section, and Mr. H. M. Napier, chairman of the General Council, undertaking the duties of croupiers. About 170 guests were present, these including the Marquis of Ailsa, Sir Samuel Chisholm, Bart.; Sir John Ure Primrose, Bart; Comte Louis de Clercq, Sheriff Boyd, Councillors Hugh Alexander and Cleland, Mr. John D. Macdonald, Professor Archibald Barr, Capt. Bennett, and Mr. Hugh Reid. "Our Guests," which was the toast of the evening, under the circumstances of the complimentary banquet to the Lord Justice Clerk, was, after being eloquently proposed by the chairman, needless to say, very enthusiastically received.

The Lord Justice Clerk, in responding in his usual humorous, albeit very earnest and convincing manner, said the truth in regard to motor cars must prevail. He looked upon automobilism not so much as a sport but as being of enormous value towards the development of the commerce and the agriculture of the country. He did not think many had much conception of the enormous effect it would have upon the wealth of the country, upon the prosperity of the country, upon the development, once for all, of the road as an interesting place, upon country inns and the people who administered to the country inn. He further advocated consideration of all users of the road one to another, and hoped that all racing at abnormal speeds might be relegated to America, rather than its further development should be encouraged in this country.

In the course of the evening a very pleasant function was performed in the presentation to Mr. Robert J. Smith, the hon. secretary, of a silver centrepiece in recognition of his services to the club.

Sheffield A.C.

AT the Annual General Meeting of the club, the following officers were elected for the ensuing year:—*President*, the Right Hon. the Earl of Effingham. *Vice-Presidents*, Messrs. Herbert Barber, E. F. Coupe, Harvey Foster, D. Gilmour, J. H. Pickford, and T. Wilkinson. *Committee*, Messrs. Jas. Barber, P. J. Benson, T. H. Firth, G. D. Flather, E. W. Hatfield, Ben Hind, W. Robinson, G. E. Senior, Dr. Thorne, and Mr. J. R. Wade. *Hon. Treasurer*, Mr. E. F. Coupe; *Hon. Secretary*, F. B. Cawood.

The Automobile Club and the Trade.

AT the first council meeting of the Society of Motor Manufacturers and Traders in their new premises, Maxwell House, Arundel Street, we understand that the chief item under consideration was the proposed arrangement between the Society and the Automobile Club, which is calculated not only to remove any possibility of friction between the club and the trade, but also to advance the general interests of the motor movement.

MOTOR CYCLING.

Land's End to John o' Groats Trial.

AT the last meeting of the Auto-Cycle Club Sub-committee the following recommendations were made:—

Awards.—That a special prize, which has been promised, be awarded to the trade rider who adheres to the daily schedule and accomplishes the best performance throughout the Trial. In addition to the usual awards, a bronze medal to be awarded to each rider who finishes at John o' Groats, together with a certificate of the performance.

Eligible Machines.—That any four-wheeled motor vehicle, where the passengers are seated one in front of the other, be eligible to compete in this Trial as a motor cycle.

Closing of Entries.—That entries close on Monday, May 14th, at the ordinary fees, but later entries will be received up to May 25th at an increase of 50 per cent.

Silencers.—That efficient silencers must be fitted to all machines. No cut-outs to be used, and if fitted to the machines, they will be sealed, so that they cannot be used.

Accessories.—It is suggested that this is an excellent opportunity to accessory manufacturers to have speed gears, speedometers, magnetos, luggage carriers, &c., officially observed and reported upon, and the sub-committee recommend that this be undertaken.

The International Cup and the French Club.

WE have never altogether admired the sporting principles which prevail on the other side of the Channel. French automobilists and French motor bicyclists are as charming as possible when they win. To keep them charming they must win everything. If they fail to do this, they usually commence a campaign for the purpose of annihilating the competition in which they have proved unsuccessful. There is something about the whole business reminiscent, not of the school, but of the nursery, in which the children who have been defeated in any particular game refuse to play that game any longer. We are referring, of course, to the International Motor Cycle Cup Race, originated by the Moto Cycle Club de France, and this year to be run in the country of the holders of the cup, viz., Austria. Last year this event was the "Gordon-Bennett" of the motor cycling world, and this it would have remained, no doubt, as long as French competitors won it. But last year an Austrian competitor carried off the prize, and now, as we stated three weeks ago, all the leading motor cycle manufacturers of France are refusing to enter for this year's event, only one French competitor, the Gillet firm, being whipped up at the last moment. As we announced in the same issue of THE AUTOMOTOR JOURNAL, the Moto Club of France simultaneously decided to arrange an International Motor Cycle Championship for the end of May. We commented then upon the obvious "squeezing out" tactics which were again apparent in this move of the French Club. Presumably, this contest will be arranged so that Frenchmen may carry off the palm. If it should so happen, in spite of everything, that it is won by a foreigner, we may anticipate with perfect certainty that the event will be abandoned next year, and another event, even more favourable to French competitors, organised. In fact, methods of winning cheap glory seem to have been reduced to a fine art by the French at the present day. In justice to the history of the French nation, one is glad to admit that it was not ever thus.

A Strong Protest from Austria.

OUR remarks in regard to the action of the French Club appear to be now echoed by those most interested in the sport. These manœuvres and tactics have evoked a strong protest from the Motor Cyclist Union of Austria. After a general protest the Austrian Motor Cyclists' Union proceeds:—

> "The Moto Cycle Club of France has determined to be represented at the test this year only by a single firm, as yet practically unknown in international competitions. At the same time it has officially decided to organise an International Championship, to take place a month before the race for the Cup."

The Austrians further express their astonishment that the French should have alleged the long distance and great cost of competing in Austria as a reason for their action, and observe very naturally that it is just the same distance from France to Vienna as it was last year from Vienna to Paris. The letter of the Austrian Union concludes with the following forcible observations, which we reproduce:—

> "We have nothing to say to the races which you intend organising or to their date, but there are traditional laws of international courtesy and of sporting custom which a nation of the importance of the French is specially bound to respect. It was France which created the International Cup, and the idea of the founders was to organise a sporting event which would enable national industries to prove their superiority by generous and pacific competition.
>
> "We are convinced that an appeal to your sporting sentiments will result in persuading you to abandon the International Championship in favour of the International Cup, or to at any rate adjourn it to another date."

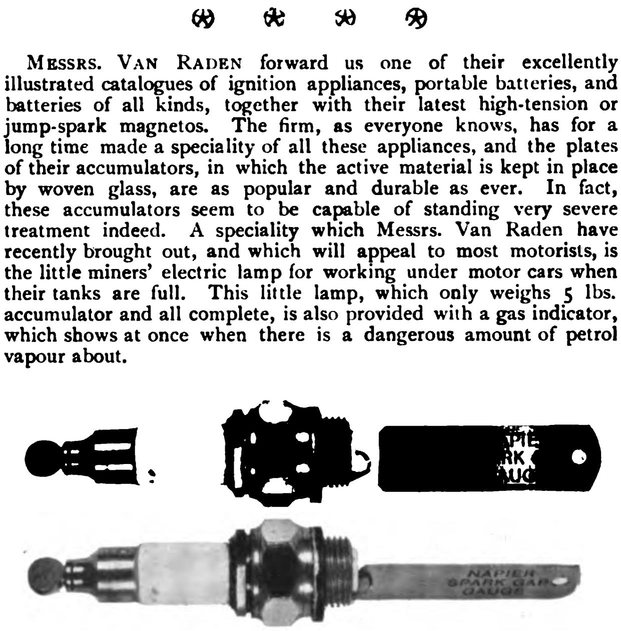
Are they?

Motor Cycles for the Army.

A VERY important departure has been made by the new Secretary of State for War, in ordering motor cycles for military purposes. The Motor Volunteer Corps has given such an excellent account of itself at manœuvres in recent years, that the importance of the motor bicycle has been fully recognised by all the military experts. That the experience gained should be given practical expression in this way by the new head of the department is an encouraging symptom. An order has been placed for the motor cycles with A. W. Wall, Limited, of Guildford. The machines are to be of the low-built type, so that the rider can easily reach the ground with either foot. There will be no pedals, but a friction-clutch permits of starting the engine in the same way as with a car. The horse-power of the engines, which will be single-cylinder, will be about 4-h.p.

* * * *

MESSRS. VAN RADEN forward us one of their excellently illustrated catalogues of ignition appliances, portable batteries, and batteries of all kinds, together with their latest high-tension or jump-spark magnetos. The firm, as everyone knows, has for a long time made a speciality of all these appliances, and the plates of their accumulators, in which the active material is kept in place by woven glass, are as popular and durable as ever. In fact, these accumulators seem to be capable of standing very severe treatment indeed. A speciality which Messrs. Van Raden have recently brought out, and which will appeal to most motorists, is the little miners' electric lamp for working under motor cars when their tanks are full. This little lamp, which only weighs 5 lbs. accumulator and all complete, is also provided with a gas indicator, which shows at once when there is a dangerous amount of petrol vapour about.



In order to enable the distance between the spark-points of an ignition-plug to be correctly adjusted on Napier engines, Mr. S. F. Edge has recently introduced the special gauge of which we give two views above. These illustrations well indicate the manner in which this simple little device is intended to be used.

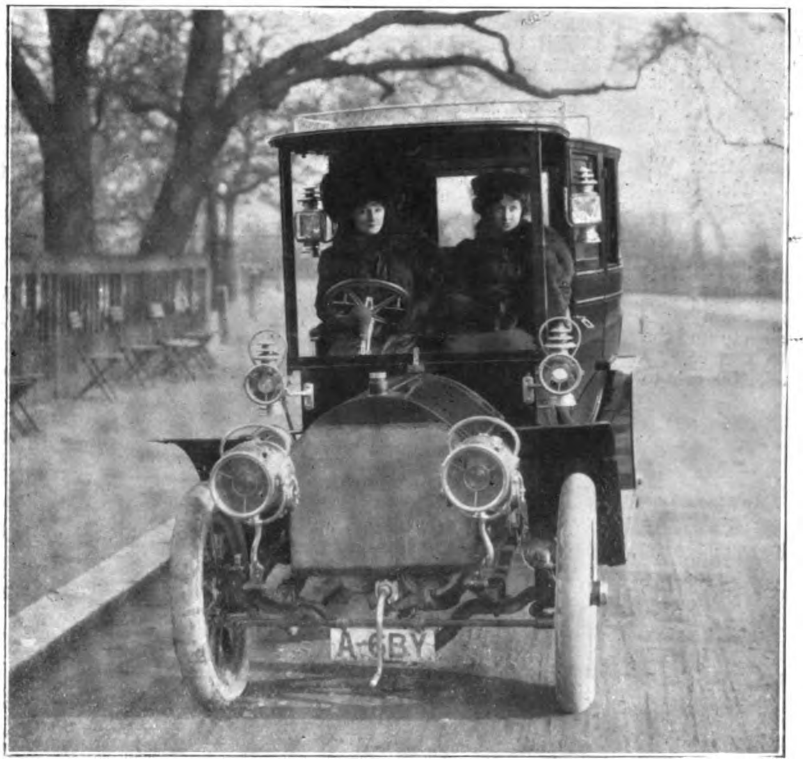


Photo by Bassano.

The Marchioness Townshend at the wheel of a 1906 type 25-30-h.p. Ariel Limousine Car.

A Trained Baby, and a Point of Law.

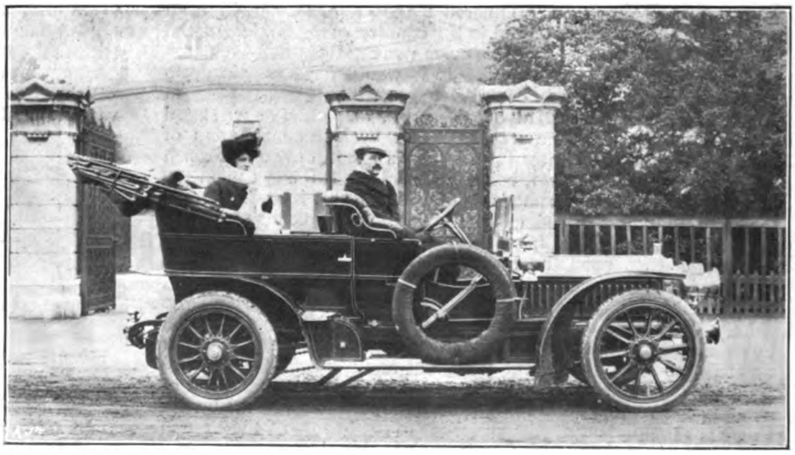
A BABY who has a proclivity for tearing inconvenient endorsements off licences, should prove nearly as useful to automobilists "with a past" as the children on the Ripley Road used to be to Sergeant Jarrett. Francis Forest, of Carrington Street, Mayfair, was summoned at Bow Street for driving a motor car in St. James's Park beyond the regulation speed. Defendant's licence was produced in Court, and the magistrate observed that a portion of it was torn off. The defendant explained that this feat had been performed by his baby, and the case was adjourned that the baby might disgorge the missing portion, which it was admitted contained an endorsement. We take this opportunity of once again pointing out (though there seems to be little good in doing so) that an accused person is not bound to produce his licence in Court until he has been convicted. Having been convicted he must produce the licence within a reasonable time (and a magistrate has said a reasonable time would be seven days) to have the particulars of the conviction endorsed upon it. But he is not bound to produce it before. This is in accordance with the principle of English criminal procedure that previous convictions must not be adduced against an accused person until he has been found guilty of the charge. It is a course that is very frequently departed from in practice, but it is the law all the same. Records of previous convictions, which is what endorsements are, should only be referred to in order to determine the punishment to be inflicted and can never legally be used as presumptive evidence of guilt. This, however, is a fact persistently ignored by the police, who insist on asking for licences as soon as the unfortunate motorist is brought into Court. The motorist should absolutely refuse to accede to this demand, as the attempts made by the police to force him to produce his licence before the case is heard are a gross abuse of their authority. However, it often helps them in obtaining convictions, and that is all *they* care about.

Mr. Cathcart Wason, M.P.

THERE are advantages in contesting the remote constituency of Orkney and Shetland. Reminiscent of ancient times, when it took a considerable period to get there, this constituency polls last of all, and the intending members have consequently ample time to see how the political cat is jumping in the rest of the country. It was as a member of the House of Commons, noted for his hostility to the automobile, that Mr. Cathcart Wason was principally known outside that assemblage. In the last Parliament he was a Conservative, but he realised how completely popular feeling had changed, doubtless by reading the results of other elections in the daily papers, and wisely he changed with it. The quondam Conservative is now a Liberal, and in consequence retains his seat for Orkney and Shetland. Whether he bears a coat of arms we do not know, but if he is in want of a suitable motto we would suggest the old one about *tempora mutantur et nos*, &c. While changing his political opinions we trust Mr. Cathcart Wason has also changed his opinions in regard to the automobile. The automobile boat, at any rate, would be useful in his constituency.

Rise, Sir Fletcher Moulton, Lord Justice.

LORD JUSTICE MOULTON last week had the honour of a knighthood conferred upon him.



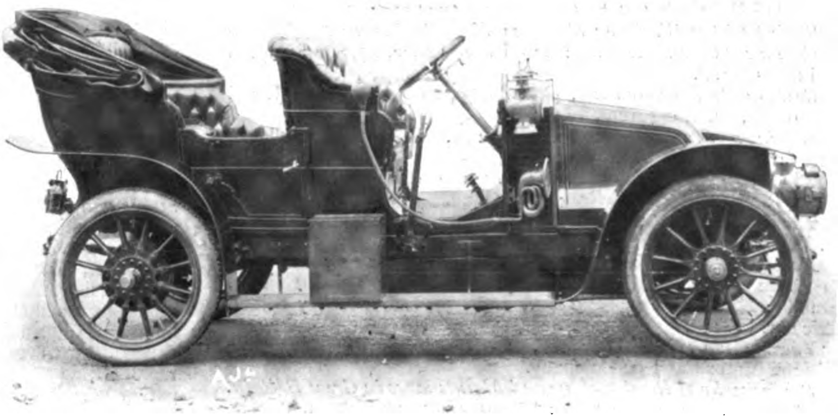
Viscount Royston and his recently-acquired 40-h.p. 6-cylinder Napier touring car. Accompanying Viscount Royston is his sister, Lady Susan Yorke, so well known as a brilliant amateur actress.

The Motor Horn Abuse.

IN Holland a new law forbids the use, by "push cyclists," of the motor horn.

A Testimonial to the "Yellow Cover."

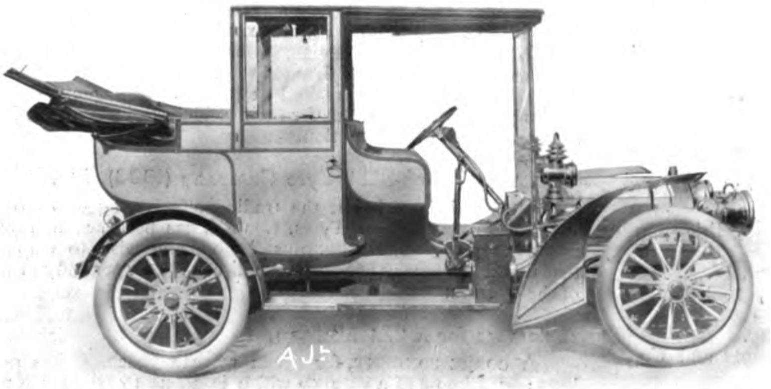
A NUMBER of books, according to a notification in the club *Journal*, have disappeared from the shelves of the Automobile Club Library, somebody apparently having chosen to overlook the information, with which he was doubtless furnished, that the library is not a lending institution. Among the various works which have disappeared are, we notice, the first three bound volumes of THE AUTOMOTOR JOURNAL, a proof that this particular "borrower" knew what he was about, and picked out volumes which have been long recognised as among the classics of automobile literature. We heartily endorse the request in the club *Journal*, that any member who, in ignorance of the rule against removing books from the library, "may have borrowed the volumes specified," will return them forthwith.



A handsome 35-h.p. Renault Car.—This Vehicle is one of the very latest models turned out from the works, and is—like all the Renault cars—remarkable for its smooth and silent running. In appearance, too, it follows the same lines as the other well-known models, having the radiator fitted close up to the dashboard and a very sloping bonnet. Its four cylinders have a bore of 130 mm. with a stroke of 140 mm., and, at the normal engine-speed of 700 revs. per min., the car is geared to 12, 30, 45 and 66 miles per hour on its respective "speeds."

The Automobile Club and the Motor Union.

A REGULAR working agreement between the Club and the Union has now been reached, which will for most purposes constitute the two organisations one body, but in which the responsibilities and duties of each are clearly defined. The relations between the Club and the Union will be regulated by a Standing Joint Committee of ten members, five to be nominated by each body, with a chairman. The Union will uphold and assist the Club in all disciplinary measures dealing with the conduct of motorists, and in all matters connected with trials and competitions, but the Club will refer cases of prosecution to the Union and support its action. In future, all agreements with local motorists and provincial clubs will be made by the Motor Union in the names of the two bodies in common.



One of the latest Italian firms to take up the manufacture of high-class petrol vehicles is the Societa Torinese Automobili Rapid, whose vehicles were, it will be remembered, shown at the last Paris Salon. Our illustration shows one of the 30-40-h.p. Landaulette Limousines, this being one of the more powerful "Rapid" models. Other standard types are those of 12-h.p., 20-30-h.p., and 50-70-h.p. Messrs. Straker and McConnell, who have recently been appointed the English agents, will have the handling of these new models.

How to Promote Gymkhanas.

THE Motor Union informs us that they have prepared a statement of hints and suggestions for the conduct of motor car gymkhanas. These suggestions have been circulated to the various clubs included in the membership of the Union for their information and guidance.

Gymkhanas are increasing in popularity among local clubs, as they are free from the disadvantages necessarily attendant upon club runs.

A copy of the suggestions can be obtained on application to the Secretary of the Union, 1, Albemarle Street, Piccadilly, London, W.

A Mile of Trams.

WE are always having fresh object-lessons in that peculiar characteristic of the electric tram, that if anything happens to stop one of the vehicles the whole line is blocked, and jammed for miles. One day last week a large furniture van was overthrown on the tramway line on Clapham Road. Before the van could be moved, the furniture had to be dragged out and placed on the pavement, an occupation which took up nearly an hour, at the end of which period there was a nice little muster of electric tramcars of over a mile in length standing end to end, partially deserted by their passengers, while even the most patient of those who were waiting for the furniture-van and the other tramcars to roll by were giving forcible vent to their feelings in language more picturesque than polite.

LEGAL INTELLIGENCE.

The Alleged "Motor School" Frauds.

AT the Westminster Police Court on the 15th inst., Riski Medawar and John Raymond Kerr were committed for trial on charges of conspiring to obtain money by false pretences in connection with an instruction school at Victoria Street, S.W.

COMMERCIAL POINTS.

H.-F. Vulcanizers in the West-End.

FOR some time past, Messrs. Harvey-Frost and Co., Ltd., have received at their head establishment in Great Eastern Street, a large number of applications, for free demonstrations in tyre-repairing, from people resident in the West of London and its environs, and as these applications are increasing daily, the firm is opening showrooms at 215, Shaftesbury Avenue (New Oxford Street end), to enable applicants to witness the demonstrations without making a journey to Great Eastern Street All the H.-F. vulcanizers will be on exhibition, including the popular little "car" vulcanizer, for carrying on car, and for executing tyre repairs by the wayside, as well as the other H.-F. appliances which the motoring public in London and elsewhere have so largely adopted. An important feature of the new showrooms is the free demonstration department, where any interested person may walk in and see tyre repairs being executed by the H.-F. process, and without any obligation whatever to purchase. This department will be a great convenience to those whose time is limited, and who find a journey to Great Eastern Street somewhat inconvenient. Specimen repairs by the H.-F. process will be available, every assistance will be given, and free inspection of the H.-F. vulcanizers and the H.-F. process will be allowed to anyone who calls. This development should inspire confidence between Messrs. Harvey-Frost and Co., Ltd., and prospective customers in the western districts of the Metropolis.

Municipal Motor Vehicles Wanted.

THE Twickenham Urban District Council have invited tenders, we learn through the British Empire Motor Trades Alliance, Limited, for the supply of the following:—One steam wagon, fitted with interchangeable bodies for street watering and cartage of materials and house refuse; six tipping wagons for the collection of house refuse. Further particulars can be obtained on application to Mr. Fred W. Pearce, F.S.I., Surveyor to the Council, Town Hall, Twickenham.

A Scotch Festival.

THE employees of the New Arrol-Johnston Car Company, Ltd., Paisley, held their first annual supper and dance in the George A. Clark Town Hall on Friday last week. Some four hundred guests were present. Mr. John S. Napier, the managing director, occupied the chair. After supper, Mr. D. B. Wright, foreman of the repair works, in proposing the toast of "The Firm," called attention to the remarkable equipment possessed by the Company for the production of motor vehicles of the highest grade, instancing the victories of the cars in the Glasgow Cup Competition and the Tourist Trophy Race as evidence of the sterling qualities of the vehicles. Mr. Napier, in responding, said, among other interesting things, that the firm was in the unique position of having designed, built, and had running on the road, three distinct types of cars within the past ten months, whilst a fourth model was now practically complete. A vote of thanks to the chairman, coupled with the name of Mrs. Napier for her presence at the function, was proposed by Mr. E. F. Robertson, assistant works manager, in acknowledgment of which Mr. Napier thanked the talented ladies and gentlemen who had sung and recited at intervals throughout the proceedings, and the committee for their assiduous efforts in making so signal a success of the function.

"Bettoruss" Non-Skid Tyre Company (1906), Ltd.

WE are informed that the trading name and goodwill of the late Bettoruss Non-Skid Tyres, Limited, has been acquired by the above company. The "Bettoruss" Company wish to emphasise that the new company has not on its directorate or staff any member of the old firm.

A Chance for a "Live" Man.

A CORRESPONDENT, for whom we can vouch, writes as follows:—"I know of a vacancy which is about to arise for a really smart man who can take a position as chief assistant in a motor depôt. It is a really good opening, indeed one of the best I have come across, for anyone who is (1) a good salesman; (2) a practical motorist. If you can insert a paragraph in your next issue, and send any replies on to me, I will treat such with confidence, and can put them in touch with the right party. It is a good chance, especially for a young fellow who wants to get on in the world, because it is with a first-class firm, with decided possibilities of rising to a higher post."

We shall be happy to forward any letters, addressed to "Motor Assistant," c/o THE AUTOMOTOR JOURNAL Office, accordingly.

Arrol-Johnston Cars in India.

Although it was unfortunate that the Automobile Association of Bengal failed to secure sufficient entries to enable them to hold their proposed Reliability Trials, yet it is satisfactory to hear that the Arrol-Johnston car which was sent to Calcutta in order to compete in that event has, before being delivered to its owner, been the means of already bringing a large number of enquiries from would-be motorists in that country. This particular type of car—both the 4-seated and the 6-seated models—is so pre-eminently well suited to the rough roads of India that it is almost safe to predict a large sale out there for the vehicles built by this progressive British firm.

Change of Address.

The British Automobile Development Company, Limited, have removed their head office to King Edward's Mansions, Shaftesbury Avenue (five doors from New Oxford Street).

Sheffield Motor Show.

The Lord Mayor has consented to open this Exhibition at 3 p.m. on Friday, March 2nd. Members of the Motor Union are specially invited to be present, and will be admitted free on production of their membership tickets.

Owing to pressure of business, the Continental Tyre and Rubber Company, Ltd., advise us that they are not showing at the Manchester Motor Exhibition, but that they are holding a special show at their new depôt, 255, Deansgate, Manchester, where a full stock of motor and other tyres, and rubber goods of all descriptions, can be inspected.

Messrs. S. F. Edge, Limited, have determined, owing, they state, to the complaints which are alleged of British manufacturers being unable to meet the demand for British-made cars, to give a guarantee to deliver Napier cars at specified dates, backed by a heavy penalty in case of non-delivery.

Viscount Powerscourt, Controller to the Household of His Excellency the Lord-Lieutenant of Ireland, has just added to his "stable" a 1906 Gladiator car.

At the International Automobile Exhibition in Berlin we learn that no less than 862 wheels were fitted with "Continental" tyres.

⊕ ⊕ ⊕ ⊕

Star Omnibus Motors.

In the directors' report of the Star Omnibus Company, it is stated that the company now have eleven motor 'buses delivered to date, and a further number are expected daily. A number of freehold and leasehold premises have been built with a view to their conversion into motor garages, and the company is therefore in an especially good position for running motor omnibuses on any route that may be considered desirable.

BRITISH EXPORTS AND IMPORTS OF MOTOR CARS, &c., FOR 1906.

Note.—In our issue for January 13th, 1906, we published in one table the full figures of British Exports and Imports for 1902, 1903, 1904, and 1905. Prior to 1902, motor cars were not classified separately.

1906.	Imports.					
	No. of Cars and Value.		Parts Value.	No. of Motor Cycles and Value.		Parts Value.
January ...	458	£ 175,270	£ 136,720	114	£ 2,889	£ 1,989

COMPANY DOINGS.

London Road Car Company, Limited, and Motors.

At the half-yearly meeting of the company, on Monday, Mr. John Howard Moore, J.P. (chairman), presiding, the chairman said that there had been considerable reduction in the receipts of the horse-drawn cars. The decrease in the horse-car receipts had been more than made good by the takings of the motor cars, with the result that the total traffic receipts were £204,417, against £200,160 for the corresponding period of 1905, and they had carried 36,275,065 passengers, against 35,687,413, the number of passengers carried by the motors during the half-year being 2,527,174. Under the heading of "Car and Motor Repairs and Renewals," the figures showed a considerable increase, but on the other hand the reduction under the head of "Horse Renewals" was even more considerable. The item of car and motor repairs and renewals had been swollen by their having added thereto the loss which they made on the sale of some motors which were found to be unsuitable for London traffic.

Replying to criticisms in regard to statements which had appeared in the Press calculated to give the impression that the directors of the company, with reference to motor traction, had practically been asleep, and had only recently become alive to a sense of its importance, the chairman epitomised what the directors had actually been doing in this matter for the past six years. He said:—"As far back as September, 1899, the directors first ordered an electric omnibus to carry 26 passengers, which was never delivered. In the following November we actually ran a Thornycroft steam car for over five months with fairly satisfactory results, but the car was withdrawn on the understanding that the manufacturers were to supply others of an improved type, and bodies were built by us in anticipation. The others, however, were not forthcoming. In July, 1901, the directors made a trial of a centre steering tractor, resulting in an order being given, but this order also was never completed. In August of the same year negotiations were entered into with an American company for another electric motor, but the proposal fell through, as did another proposal in the following month for a hydroleum liquid fuel motor. In May, 1902, a contract was made with another American company to deliver three electric motors to carry thirty-two passengers. Delivery was to have been made within three months of the date of the agreement. They did not, however, come to hand until some considerable time afterwards, and consequently the directors of this company intimated that in view of the delay, and of information regarding their working, which was unfavourable, they would be declined. So anxious was the Board to take the lead in introducing mechanical traction that about this time (1902) a tractor was built by the company at their car factory. The design, however, as might perhaps have been expected at this early stage in the evolution of the motor 'bus, was not quite perfect, and, after a good deal of experiment, the tractor idea was abandoned for good. In February, 1903, a contract was entered into for six Daimler motors, and the company built the bodies for these cars. The company was never able to get delivery of these motors, and the bodies have in consequence been used on motors purchased from other makers. I will not weary you with further particulars, suffice it to say the list has by no means been exhausted, and that one and all only brought us disappointment. At length, towards the close of the year 1903 and the beginning of 1904, we made trials with some motors—one propelled by steam and the others by petrol—which really gave us hope of ultimate success. As a consequence of these trials and of the successful running of motors in provincial towns, in December, 1904, the Board came to the conclusion that the experimental stage of motor vehicles had been passed, and consequently placed orders with makers of reliability, stating by circular to the shareholders, dated 2nd January, 1905, that in the opinion of the Board of Directors the time had arrived when the operation of substituting mechanically-driven vehicles for the present horse cars should be seriously commenced, and the existing horses and cars disposed of by degrees.

"You have thus seen that for five or six years the directors have been using every effort to secure a machine which would be quite suitable for the public service. When this was on the eve of fulfilment last year, the promoters of several new motor omnibus companies, who had done nothing to aid the evolution of the motor

'bus, appeared on the scene and appealed to the public for funds to enable them to oppose ourselves and other omnibus proprietors, who for all those years had been trying to solve the problem, and the Press, while ignoring our efforts, had nothing but praise for these so-called pioneers. A considerable amount of promotion money must have accrued to these promoters. The ultimate fate of the companies remains to be seen. But the appearance of the newcomers in the field has had the effect of modifying the programme which your directors had mapped out for themselves, namely, to carry out the substitution of mechanical for horse-power gradually. It must be perfectly obvious that the horse drawn car can have no chance against the swifter running motor, and the substitution of the one for the other must therefore be now accelerated and carried through with the utmost possible expedition. The directors are extremely sorry that circumstances have been as described, as in their opinion the evolution of the perfect motor would have been ensured during the period of substitution had it been carried out gradually. The process of substitution will involve a sale of horses far in excess of the number which have ordinarily to be disposed of in each half-year, as well as the putting out of service of the horse cars. The value of horses, cars and harness, which, during the year 1905, have thus been put out of service, is about £30,000, about £20,000 of which have been paid out of revenue, which, under the circumstances, the directors think is very satisfactory, as in addition a reserve account for the depreciation and renewal of motor chassis of £1,000 has been started.

"As regards horse cars for the past ten or eleven years we have built our cars of teak instead of ash. These cars can be enlarged for service as motor bodies of the standard size and type at a comparatively small cost, and we, by adopting this course are able to affect a saving of from £15,000 to £20,000 as between the cost of conversion and that of building entirely new cars. By the second half of the year the greater proportion of the company's stock will have been substituted."

NEW COMPANIES REGISTERED.

General Motor Carrying Company (Limited), 3, York Street, Manchester.—Capital, £50,000 in £1 shares. Object, to carry on the business of general carriers by motor wagon between Manchester and other towns in the Lancashire district. First directors, W. Kay (chairman), W. H. Collier, G. Paton, J. W. Thompson, and J. Miller.

The Glasgow Motor Haulage Company (Limited).—Capital, £20,000 in £1 shares. (Scotch Co.)

Gould Brothers (Limited).—Capital, £2,500 in £1 shares. Object, to acquire the business carried on by E. Gould at 4 and 5, Southernhay, Exeter, as Gould Brothers, of carriage, motor car builders, &c. First directors, E. Gould and G. H. Stephens.

Hartridge Indo-American Tyre Syndicate (Limited), 42, Granville House, Arundel Street, Strand, W.C.—Capital, £3,600 in £1 shares.

International Motor Insurance Company (Limited).—Capital, £100,000 in £1 shares. First directors, J. Broadley, R. M. Bottomley, A. S. Bury, H. Lonsdale, and J. D. Lonsdale.

London and Counties Motor Omnibus Company (Limited).—Capital, £100 in £1 shares.

New Ellis Motor and Cycle Company (Limited), 120, High Street, Watford, Hertfordshire.—Capital, £1,000 in £1 shares. Object, to acquire the business carried on at 120 and 122A, High Street, Watford, as Richard Ellis, of manufacturers and agents for motor omnibuses, &c. First directors, R. Ellis and J. Appleford.

Penrith and District Motor Service (Limited). — Capital, £5,000 in £1 shares. Object, to carry on the business of carriers of passengers and goods. First directors, E. Jackson, J. Altham, J. Thornborrow, H. Jackson, and W. F. Winn.

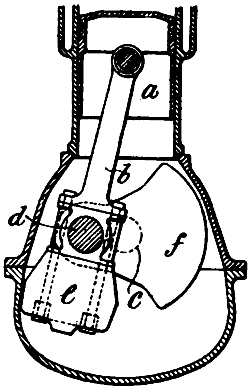
NEW ISSUES.

The Provincial Motor 'Bus and Traction Company (Limited), whose authorised capital is £305,000 in 300,000 ordinary shares of £1 each and 100,000 deferred shares of 1s. each, are issuing the 300,000 shares at par. The primary object of the company is to extend the use of motor 'buses and other forms of motor traction in the English provinces and in Wales, Scotland, and Ireland. The company will be a parent company for the following among other purposes: To establish services of motor 'buses and other motor vehicles in and around various towns in England, Scotland, Wales, and Ireland, under the direct management and control of the company; to form subsidiary companies to run motor 'buses and other motor vehicles under the direction of local boards with representatives of the parent company; to enter into arrangements with municipalities and other local authorities, railway companies, tramway companies, and others for running special services of motor 'buses and other motor vehicles; and to provide express motor deliveries of parcels, goods, &c. Amongst the manufacturers whose chassis it is proposed shall be employed by the company are Messrs. Sir W. G. Armstrong, Whitworth and Co., Ltd., Panhard-Levassor, and Milnes-Daimler. The British Motor Trust, Ltd., are the promoters of the company, for which services they receive £8,000 in cash and the whole of the deferred shares (fully paid).

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

11340. 30th May, 1905. Improvements in Balancing the Moving Parts of Engines. Sir W. G. Armstrong, Whitworth and Co., Limited, and Walter G. Wilson, both of Elswick Works, Newcastle-on-Tyne. This invention relates more particularly to explosion engines, but is also applicable to steam and other engines. For the purpose of balancing the moving parts a weight is attached to the connecting rod on the other side of the crank pin to the cylinder. This weight and its distance from the crank pin should be such that the centre of gravity of the piston, the connecting rod and weight, is at the crank pin. There is one drawing, a section of a part of an engine; *a* is the piston, *b* the connecting rod, *c* the crank shaft and *d* the crank pin, *e* is a weight attached to the connecting rod, such that the centre of gravity of the piston, *a*, the connecting rod, *b*, and the weight, *c*, is as near as may be at the centre of the crank pin; *f* is a weight attached to the crank, such that the centre of gravity of the piston, *a*, the connecting rod, *b*, and weights, *e* and *f*, is as near as may be at the centre of the crank shaft.—January 31st, 1906.



1482. 25th January, 1905. Improvements in Electrical Contact Makers and Breakers. Percy W. Noble, Beach House, Dale Street, Leamington. This invention relates to electrical contact makers and breakers, and has for its object to provide a simple low-tension contact maker and breaker suitable for the electric ignition of internal combustion engines. In this invention a tube containing mercury and a conductor are in the path of the primary corcuit, and the conductor is adapted to be dipped mechanically into the mercury and withdrawn, to cause the closing and opening of the primary circuit. The mercury is contained in U tube, and the conductor dipped into one branch, whilst in the other branch an adjustable plug is inserted, so that adjustment of the level of the mercury can be obtained as required. There is one drawing—an elevation. The ignition cam is mounted on the half-speed or other shaft and co-operates with the end, B^1, of a rocker, B, pivoted at B^2, to a suitable insulated base-plate, C. This rocker, B, carries at its end an adjustable conductor, D, which is arranged to dip on movement of the rocker, B, into a U-tube, E. The U-tube is carried in any convenient manner, as by the base-plate, C, or an insulated arm, F, and is filled to a convenient height with mercury. Into the other end of the U-tube dips a second conductor, G, adjustable as shown To this conductor, or to a terminal, G^1, thereon, is led a primary wire in the usual manner. In operation, when the cam, A, engages the rocker, B B^1, the conductor, D, will be dipped into the mercury, and the current, led thereto by the wire to the terminal, G^1, will be earthed.—January 31st, 1906.

The AUTO MOTOR JOURNAL

A Record and Review of Applied Automatic Locomotion.

No 269. (No. 9, Vol. XI.)] MARCH 3RD, 1906. [Registered at the G.P.O. as a Newspaper.] [Weekly, Price 3d. Post Free, 3½d.

"A TRY FOR THE HERKOMER TROPHY," was the title of an interesting paper read by Mrs. Edward Manville before the members of the Ladies' Automobile Club of Great Britain and Ireland last week. This chatty résumé of Mrs. Manville's participation in the various trials for the famous Herkomer Trophy we reproduce in this week's issue of "The Automotor Journal," together with a number of the charming photographic views with which Mrs. Manville's paper was illustrated. The above are some of those referred to in her paper, three of them representing scenes at different frontiers which were passed by Mrs. Manville and her party. The top left picture is unique, as it shows the car half in Switzerland and half in Germany. The picturesque photograph at the bottom on the right, is at Ettal, where a visit was paid to the very quaint old monastery.

PASSING EVENTS.

The Occultation of Headlights.

For many months—we might almost say years—everybody has been hammering away at the unnecessary and disconcerting glare which the headlights of so many motor cars diffuse before them. There has been a great deal of feeling on the subject. Ladies on bicycles, when fixed by the brilliant gleaming eye approaching them rapidly out of the dark, become confused and embarrassed, and convey their confusion and embarrassment to their iron steeds, which wobble in consequence from one side of the road to the other, to the imminent danger of the lady riders, and the unspeakable terror of the driver of the car; horses stand upon their hind legs or jib with terror in the middle of the road, devoutly believing that "the last day" which they have been told about in their youth, has come at length, and even ordinary pedestrians hold on by the twigs of the nearest hedge, so as to be sure of getting out of the way of the approaching danger as completely as possible. To look at the matter seriously, there is no doubt that an excessive glare on the front of a car, particularly in more or less effectively-lighted towns, is at times an annoyance and even a danger to other users of the road, and we have always deprecated the employment of headlights that produce it. We are accordingly glad to see that there is a probability of combined action on the part of the Automobile Club and the Motor Union. Trials and tests of headlights are now being conducted by the club, and the Motor Union has pointed out that this would be a good occasion "to encourage manufacturers to design and make a lamp which, while meeting the requirements of automobilists, should not give any ground for reasonable complaint from other members of the travelling public." It would seem, in fact, that what is really needed is a variable headlight. In shadowy country roads, where vehicles are few and far between and where such carts as are met with have no lights behind them, and above all, where turnings are frequent and sudden, a powerful headlight is a practical necessity for the automobilist, however slowly he may be travelling. Where he comes into lighted districts, however, the light that is justifiable and even needful in the country, becomes a public nuisance, and there he ought to be able to veil or diminish its splendours to the necessary extent. It must not be forgotten, however, that one of the principal reasons of the introduction of the powerful headlight on a car has been the absence of tail-lights on ordinary horse-drawn vehicles. The proposal to moderate the power of headlights, therefore, should have some connection with a guarantee that legislation to render the use of tail-lights universally compulsory should be introduced at an early date.

◆ ◆ ◆

Methods of Overcoming the Difficulty.

There are several ways in which the variable headlight—the headlight that can be made bright when required, and only moderately brilliant where excessive brightness would be a nuisance—can be designed. One method, which we illustrated in the Journal, consists of employing curtains in front of the burner. This seems rather a wasteful method, as it means employing a powerful source of light, and then damping it down without any corresponding economy in cost. Another method which has been proposed, and is, we believe, the subject of patent applications in this country, is to employ gas of moderate illuminating power for lighting the headlights and automatically enriching it to a greater or less extent with acetylene when required. This is easily done by having a certain amount of calcium carbide arranged in a receptacle inside the gas connections, when a few drops of water, allowed to fall upon the calcium carbide, will instantly disengage a copious supply of acetylene, which will treble or quadruple the illuminating power of the gas flames employed. Electricity, too, has its merits. The more general introduction of combined lighting and ignition plants, in which a small battery, which can work the ignition coil and furnish current to incandescent lamps, has its place on the car, provides, perhaps, the best and most satisfactory solution. A group of small incandescent lamps can be arranged inside the headlight, one only of which, say, is switched on where a small light is needed, the whole bunch being illuminated when high power is required. Electric lighting, too, has the great advantage of enabling the driver of a car to be absolutely certain that his rear light is burning, as he can have a small light or other indicator in series with it on the dashboard. If this dashboard-lamp is burning, he may be quite certain that his rear lamp is also illuminated, an assurance with which he is not provided by any ordinary system of car lighting.

◆ ◆ ◆

Lady Elizabeth and the Juggernaut—A Tale of a Tragedy.

Of course, no one would suspect the Highways Protection League of being capable of writing a novel, but if appearances and "language" count for anything, they have been aiding and abetting Miss Evelyn Everett Green to do it for them, and she has risen to the occasion. Doubtless, she has been supplied gratis by the League with all the remarks which its members, associates, and friends have made about the automobile for some years past, and the result is that Miss Everett Green raises a complicated shriek in fifteen flats and thirty-seven sharps that would do credit to Miss Corelli when disputing with any who do not adopt her special brand of Christianity, or suggest that Shakespeare did not write all the plays that go by his name. Miss Green's characters are divided into "demons on wheels" and anti-automobilists of the regular time-honoured, thickly-crusted, and stereotyped variety. To the latter category belongs Lady Elizabeth. She will not allow a motor car inside her park gates, and she is backed up by a Miss Flemyng, an elderly spinster, who talks yards and yards of the most egregious twaddle about her poor garden, and how her flowers, which she had brought up on the bottle or fed out of her hand, or something of that kind, are gradually succumbing to the dust. The automobilists, on the other hand, are a "parcel of empty-headed idiots with long purses and no brains who go flying through the country in an absolutely selfish and senseless fashion seeking nothing, hearing nothing but their own hooters and screeching engines," and leaving behind them one continuous pulp of children, dogs, and other four-footed creatures. Two such maniacs are Lady Betty and her brother, Lord Rendover. But ultimately, like all wicked people in good novels, they get converted. Lady Betty is converted by an attempted abduction, after which she always goes on foot (though why she should be any more difficult to abduct when footing it, is not apparent), and Lord Rendover is converted by an accident, in which he seriously injures a little girl.

Finally, before finishing the perusal of the work, we were delighted with the truth of our own perspicacity displayed in the first lines of what we have said above, for there fluttered from the pages of the egregious publication a printed slip which sets forth the interesting information that anybody can become a member of the Highways Protection League who is willing to pay five shillings per annum for the privilege. "*Das also war des Pudels Kern!*"

◆ ◆ ◆

The Road Club.

That the automobile would be sure, sooner or later, to restore something of the old-fashioned charm of English roads is a point on which we have always felt certain. It is, accordingly, with satisfaction that we hail the formation of the Road Club, the principal object of which is to bring the automobile traffic of the present day to the assistance of the almost extinct and moribund inns with which the surface of the British Islands is strewn. Many a charming old hostelry of this kind—we could name plenty of them—has got into difficulties, and even gone under altogether in the struggle for existence, just before the advent of the motor car was destined to place others on a fine commercial basis once again. It was the old inn parlour, with its scoured bricks and fireplace brassware, that provided the sort of atmosphere in which Thackeray, Goldsmith, Sir Joshua Reynolds and Sir Richard Steele delighted. Let us trust that the Road Club will save them from extinction, for the literature of past centuries owes them a considerable debt. At any rate, the Road Club is making a good try to effect this object. Its membership, which includes such names as the Duke of Sutherland, Lord Montagu, Earl Fitzwilliam, Earl Roberts, Lord Suffield, Lord Northcliffe, the Hon. Arthur Stanley, &c., is arranging for a number of old-fashioned inns to become headquarters of the club. The numbers of automobilists who really use the automobile for travel, just as a century ago people used the stage coach for the same purpose, or the private chaise, is becoming more and more numerous, and if, under the auspices of the Road Club, our picturesque old inns polish themselves up inside and become up to date as regards comfort and cuisine, there is no reason why the Road Club should not be successful in rescuing from destruction, just in time, one of the most picturesque elements of old English life, and one for which this country was in past centuries so justly and so widely famous.

◆ ◆ ◆

Building on Misconceptions—Steam and Electric.

One of the pieces of sound advice which the wise man gave his son on going out into the world was that "you should never take grievance-mongers too seriously." There have been some grievance-mongers who have complained that the steam car (of course a particular steam car) has not had fair treatment generally, and quite a long time ago—they have either changed their views since or become extinct—there were people who thought, or at any rate maintained, that the electromobile had not had a fair show in the columns of the automobile Press. Few people have, we should imagine, ever taken these exploiters of imaginary grievances very seriously. It will therefore be a cause of no small amusement to them to find that the alleged misfortunes and persecutions of the steam car and the electromobile are furnishing a pretext for starting a new motor paper, to be specially devoted to the interests of these oppressed and persecuted branches of the industry. We greatly fear that its life will be a short one, and unlike the short life of Achilles, not compensated for by very permanent celebrity. The fact of the matter is, that the whole idea is based on a misconception. It is simply ludicrous to maintain for a moment that either the steam car or the electromobile have not had a fair show and a fair hearing in the automobile Press. In THE AUTOMOTOR JOURNAL alone, some scores of pages in the last few years have been devoted to the various types of steam car, and if the great law of the survival of the fittest seems to have definitely pronounced in favour of one particular type of steam vehicle, that is certainly compensated for by the extreme popularity which that vehicle itself has attained. Certainly neither in this country nor elsewhere do its representatives feel themselves aggrieved persons.

As regards the electromobile, there was a time when there seemed a probability that it would hold its own as a touring vehicle. Since then it has proved itself to be pre-eminently the vehicle for town use, and pre-eminently *not* the vehicle for any other purpose. But in the days when the electromobile was struggling to show what it could do, we certainly (and we were not alone) did all that possibly could be done to keep the public well informed concerning its constructional details and its merits. That it has not succeeded in a wider sphere than that for which it seems to have been marked out by nature, is only one of the many cases of specialisation of function which we see in the mechanical not less than the organic world.

It simply will not do to attempt to found a newspaper on imaginary abuses or imaginary grievances. The mere fact that in doing so, two such totally unhomogenous interests as those of steam and electric cars have to be amalgamated, is quite sufficient to show the untenability of the position.

The Automobile Association becomes Exclusive.

WE all know the good work that the Automobile Association has done in the past, what a weight of trouble it has taken off the over-burdened shoulders of borough and county magistrates, who have been able to go home to lunch, or at any rate to dinner, at hours which, but for the benign interference of the Association, would have for ever have remained impossible. The police, too, have been spared an immense amount of time and undignified self-effacement in the umbrageous thickets and pigstyes of the Ripley Road and other places. These classes, no doubt, recognise the good work that has been done by the Association in discouraging and repressing driving at excessive speeds. Hitherto the Association has worked for the benefit of the cause, making no exceptions to persons. From now on, the advantage of being restrained from breaches of the law by means of its scouts is to be confined to its members, and they will be provided with a secret sign or symbol of some kind affixed to their cars, which the Association's scouts will then recognise, and it is only cars which are thus distinguished which the scouts will warn, either that they appear to be proceeding beyond the legal limit, or that there are "rocks ahead." We think, however, that as the Association has always maintained that its *raison d'etre* is to prevent breaches of the law by motorists, they should at least warn *everyone* driving at a speed apparently excessive. Other information may, of course, quite properly be reserved for members.

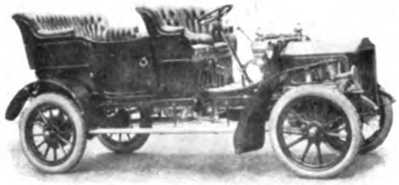
How to Recognise the Cars of To-day.

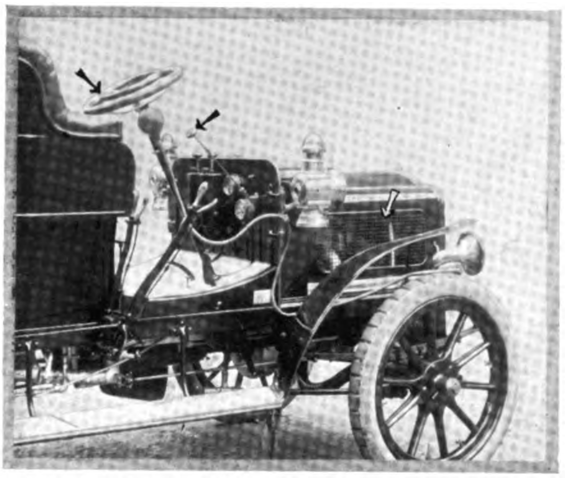
(No. 7).

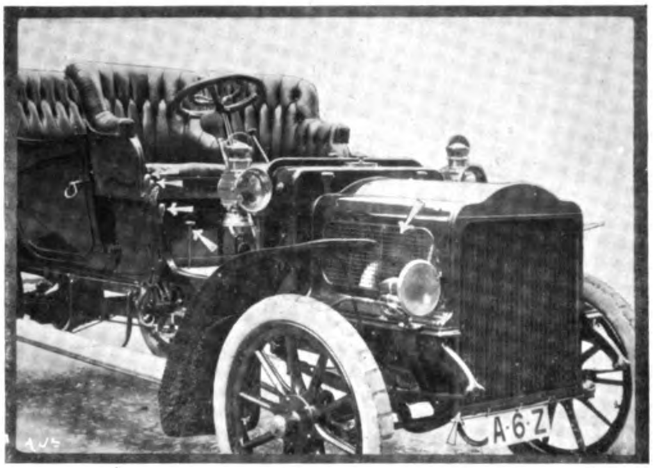
The White (Steam).

(AMERICAN)

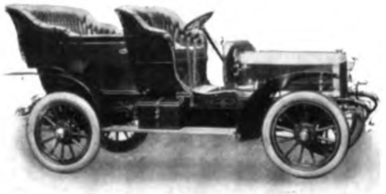
15 H.P. & 18 H.P.







The 18 h.p. model—manufactured in America—is of the live axle type. Not easily distinguishable from an extremely quiet petrol vehicle, it has nevertheless many characteristic features. The RADIATOR projects below the frame, there are WIRE GAUZE PANELS IN THE BONNET, the THROTLE WHEEL is prominent above the steering wheel, the fittings on the dash are distinctive, and there are three hand levers at the side. None of the earlier (15 h.p.) cars have side entrances. (See "AUTOMOTOR," Vol. X., 30th Sept., 1904).

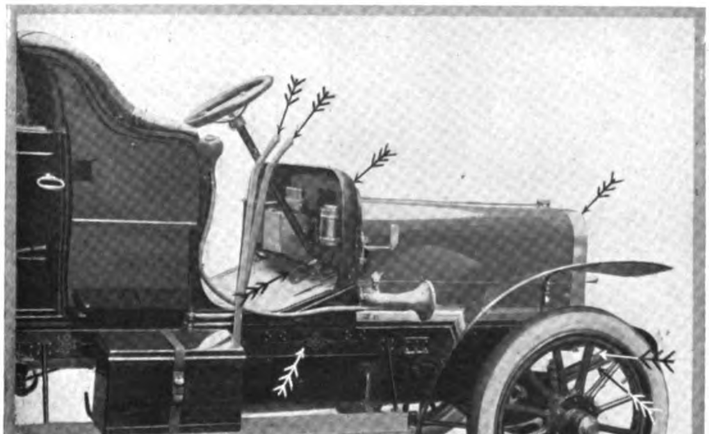


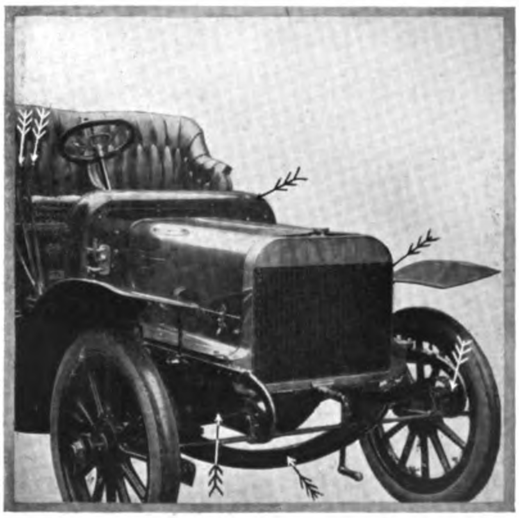
(No. 8).

The Winton.

(AMERICAN)

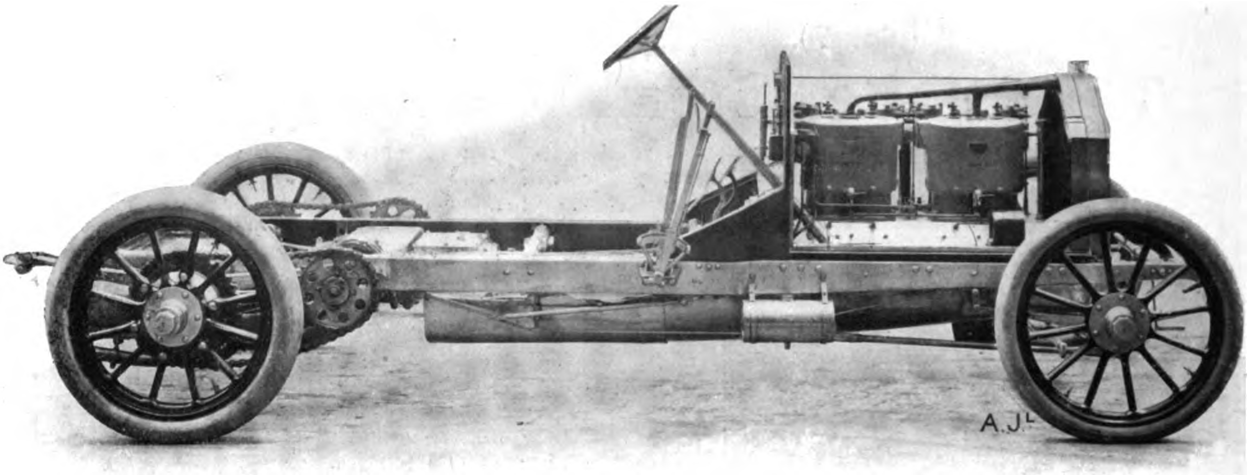
16 & 25 H.P. (Vertical).





All Winton cars can be identified by the TWO SIDE LEVERS, and by the ORNAMENTATION of the main frame. Both the present models have distinctive RADIATORS, BONNETS, AND DASHBOARDS, while equally unusual are the DOUBLE SPRINGS (back and front) and the large manganese-bronze FRONT AXLE.

THE 60-H.P. DE DIETRICH CAR.

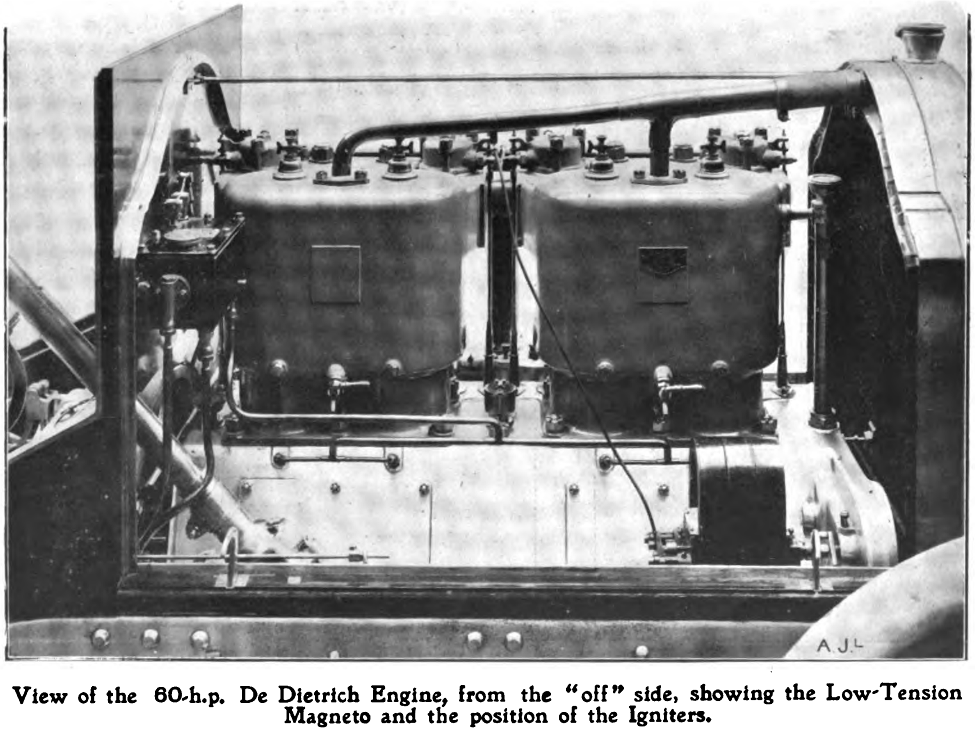


Side view of the 60-h.p. De Dietrich Chassis.

ALL the leading characteristics of this carefully-designed and well-built De Dietrich vehicle are similar to those of the less powerful (12–15-h.p.) model that we described with a number of illustrations, at the time of the last Olympia Show (*see* THE AUTOMOTOR JOURNAL of November 25th and December 2nd). It is, in fact, a large edition of the same car, as will be recognised by comparing our present illustrations of the engine and of the chassis with Fig. 3 and Fig. 5 respectively of our former article.

Much more room is naturally occupied by the engine, for the cylinders have a bore of 150 mm. and a stroke of 175 mm., while one of the very few respects in which this 60-h.p. vehicle differs radically from the neat little 12–15-h.p. car, is also to be found in connection with the engine. We refer to the substitution of a low-tension magneto system for the high-tension magneto on the smaller model, and we would draw particular attention, in our present photograph of the large engine, to the manner in which the make-and-break igniters are fitted above the cylinder-heads in such a manner that they can be easily and bodily removed, and can also be operated from the same cam-shaft as the valves. We need hardly say, moreover, that Messrs. Jarrott and Letts also fit their special "C.J.L." supplementary battery apparatus as a stand-by—as also for facilitating starting — on any of these cars, if desired.

The particular vehicle from which our photographs were taken is the first of this type to make its appearance over here, and we understand that it has already been sold to Mr. R. Douglas Croall, of Edinburgh. Amongst the unusual features of the present De Dietrich models, it will be remembered that universal-joints are introduced into each end of the differential countershaft, and that an ingenious spring-cushion device—forming a part of the operating mechanism—enables the hub-brakes to be applied progressively instead of with any degree of suddenness.



View of the 60-h.p. De Dietrich Engine, from the "off" side, showing the Low-Tension Magneto and the position of the Igniters.

PERMANENT TYRE REPAIR, ON THE ROAD.

Nothing that tends to reduce the cost of tyres, and the annoyance of repeated tyre-troubles, can fail to appeal with special force to every motorist, and we are therefore convinced that not a few of our readers will take a very strong interest in the descriptive article that we are now able to give concerning the construction and manipulation of the latest portable vulcanizer which has been put on the market by Messrs. Harvey Frost and Co. This type of vulcanizer is not, however, altogether a novelty to them, for we published a somewhat similar article in our issues of September 23rd, September 30th, and October 7th last, in which we dealt in equal detail with what was at that time the latest "H.-F." apparatus. It is not therefore necessary for us to begin at the very beginning on the present occasion, to set forth the general principles of vulcanizing, or to explain the vast difference that there is between a vulcanized repair and an ordinary roadside makeshift, but our chief object now is to bring before their notice a smaller, lighter and altogether more highly developed form of vulcanizer that not only enables inner tubes to be repaired when punctured, but is also equally applicable for making good any damaged outer covers. Incidentally, nevertheless, attention should be directed,

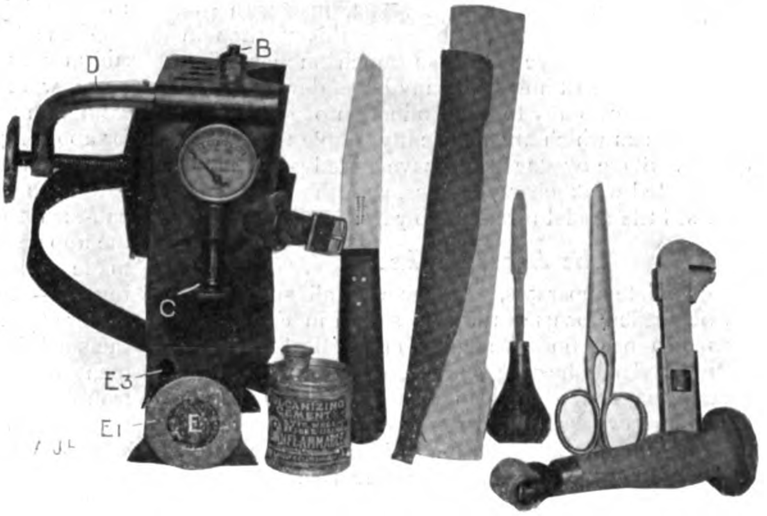


Fig. 1.—The "H.-F." Portable Vulcanizer for Motorists. View of the complete apparatus, together with a few tools that are useful when making Tyre Repairs with it.

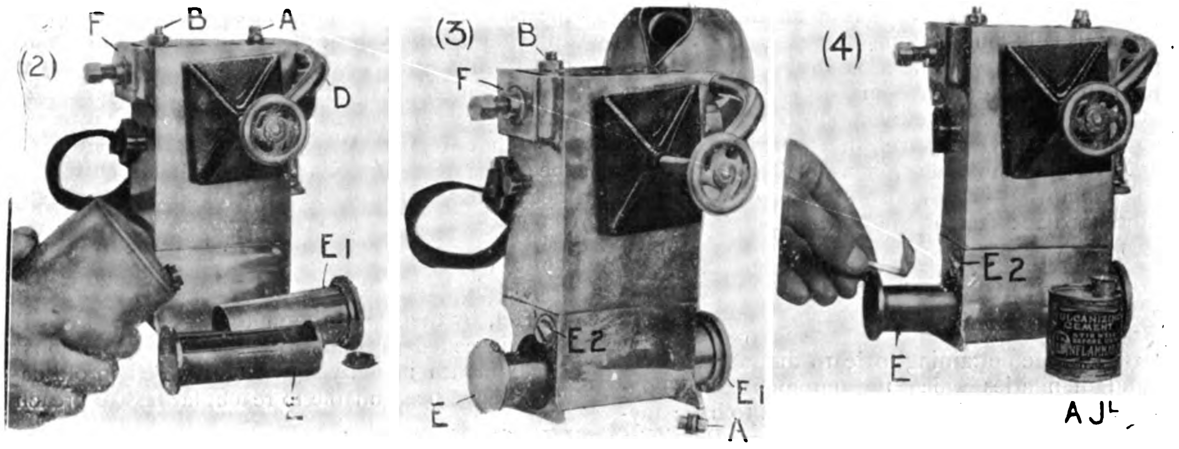
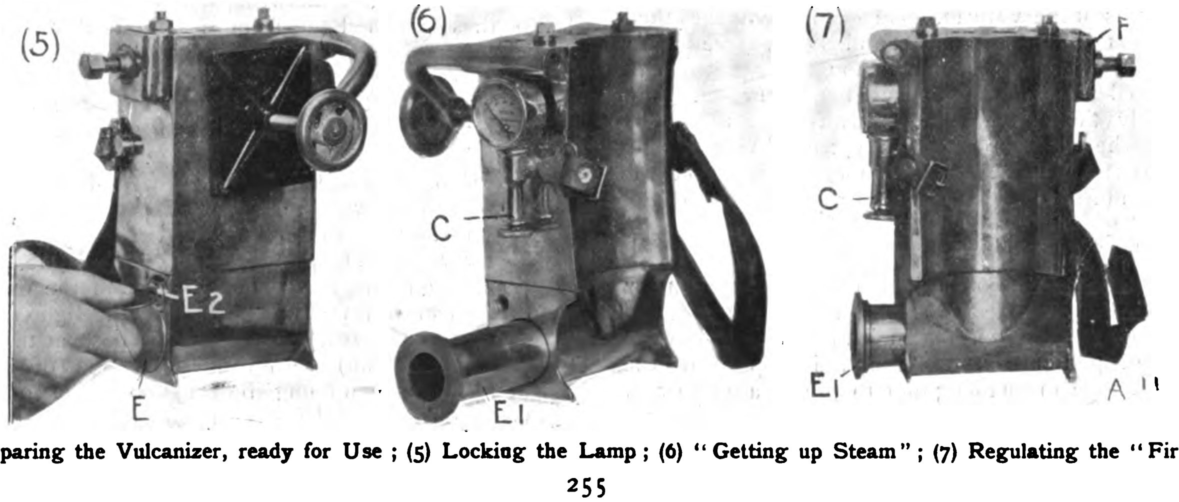


(2) Filling the Lamp, E; (3) Filling the Boiler; (4) Lighting Up.



Preparing the Vulcanizer, ready for Use; (5) Locking the Lamp; (6) "Getting up Steam"; (7) Regulating the "Fire."

before passing on from generalities, to the vast importance, in practice, of effecting an immediate repair as soon as possible after a tyre has been injured, for not only does a small cut rapidly develop into a serious wound, but there is a strong tendency for rot to set in, inside the fabric of the tyre, and for the whole cover to be rendered useless. It is, in fact, just with the object of enabling motorists to make this "stitch in time"—which can save them so much money—that Messrs. Harvey Frost and Company have devoted their attention so successfully to the production of small portable vulcanizers which are sufficiently simple to be used by anyone. Stage by stage, they have added good points and eliminated weak characteristics, with the result that their latest little model is remarkably handy and efficient.

The Apparatus Itself.

The complete apparatus, together with all such tools as can be needed for use with it, is shown in Fig. 1. It consists of a neat boiler, having four vertical fire-tubes for giving a large heating surface, and a compact little spirit lamp that slides into place beneath. At the top of the boiler are two small fittings, fixed by screw-threads, these being the filler-plug, A, for introducing the water, and the safety-valve, B. On one side is a combined steam-gauge, air-vent, and blow-off cock, C, the cock serving the triple purpose of allowing the air to escape when filling the boiler, of indicating when sufficient water has been poured in, and of being used as a "try-cock" to ascertain whether there is still water in the boiler or not after the apparatus has at any time been in use for an unusually long period.

In Figs. 2 to 7, the vulcanizer is shown from several different points of view, in some of which it will be noticed that its front face is curved out to fit around the outside of an ordinary tyre cover, that straps are secured to it for holding it in place on a road-wheel, that a detachable clamp, D—which also serves as a handle—enables the flat back face of the vulcanizer to be used for the repair of inner tubes, and that there is a socket, F, formed on the opposite side to the pressure-gauge fitting; this socket, F, enables the vulcanizer to be attached to the rear lamp-bracket of a car, so that it can conveniently be used in that position for making small repairs or can be fixed there temporarily while "getting up steam."

Of the lamp, E, itself comparatively little need be said in view of its simplicity, for it merely consists of a gauze wick enclosed in a partly cut-away cylindrical casing, and can hold sufficient methylated spirit to burn for about 45 mins. without refilling. It can be slid into place beneath the boiler from the side opposite to the steam-gauge, and is then locked in place by giving a half-turn to the screw, E^2, while, from the other side of the apparatus, the regulating shield, E^1—which can be made to more or less extinguish the flame from the burner—can be pushed in or drawn out as may be required. For lighting up the burner, when in place, the small hole, E^3, is provided. By the special arrangement adopted, the vulcanizer can be used without trouble in the open air, even though there may be a strong wind blowing, for the lamp is well protected from adverse air currents, and the vertical tubes ensure an effective up-draught.

Quite a small amount of space is occupied by this very compact little vulcanizer, which fits into a neat leather case that can quite easily be stowed away on a motor car, and weighs no more than about 7¾ lbs. For use with it, the only essentials are a tin of the specially prepared vulcanizing solution, a brush for applying it, and a sheet of rubber compound from which the freshly built up portions of a damaged tyre are manufactured, by means of the heat and pressure of the vulcanizer. Our first illustration shows, however, some tools that are particularly useful in the manipulation of the apparatus—a sharp knife, a small curved rasp, a metal roller, a pair of scissors, and an adjustable spanner.

(*To be continued.*)

* * * *

The Pope Not a Convert.

It is rather entertaining to learn that amid all the Courts and dignitaries which the automobile has conquered, there is one which steadily refuses to have anything to do with it—the Court of the Supreme Pontiff at the Vatican. The present Pope is anti-automobile in the fullest sense of the word, and absolutely refuses to admit a motor car of any kind or description within the sacred walls of the Vatican. He even discourages their use amongst the sacred college, and, so far, there is only one cardinal who has been rash enough to set at nought the Papal interdict. Considering, however, how thoroughly the automobile is justifying its use by enabling the clergy to carry out extended visitations in other parts of Italy, one cannot imagine that the opposition of the Vatican will be permanent.

Another Episcopal Car.

We have referred on several occasions to the use to which the automobile is being put by a number of Bishops of the Church of England. The Bishop of Worcester, particularly, has found its speed of the greatest service in enabling him to preach a number of sermons to a number of different people far in excess of anything which he could have accomplished otherwise. In fact, by the use of the motor car the vigorous Bishop has succeeded in delivering some fifty sermons in a single month in outlying villages which in old days he would have been unable to reach, far less to preach in.

Who is the Lunatic?

There are weird occurrences taking place at Grove Hill—and the local police force seem inclined to maintain that "there be wisions about." One of the last of these assumed the form of a dummy policeman suspended, as if he had been duly lynched, from the arm of the danger signal which the Middlesex County Council has affixed at the top of the hill. It transpires that this "portent" was substantial enough, and not a mere materialisation of psychic phenomena, for the figure, instead of being stuffed with cold pie and stout, was filled up with straw. Previous to this, a police constable on duty at the spot had been mysteriously called away by the sound of a police whistle, after returning from which excursion he found the danger sign broken and smeared with tar. Why the sign cannot (subserving as it does a most useful purpose at the top of a dangerous hill) be let alone is one of those phenomena which nothing but a knowledge of the habits and customs of the local lunatics would enable us to explain.

MEASURING POWER AT THE ROAD WHEELS.

IT is strange, in view of the universal demand of motorists to know what actual power they have available on the road wheels of their cars, that there are not already accessible one or more public, or at least semi-public, testing machines installed for this purpose in Great Britain. One frequently hears owners of cars asking how they can ascertain accurate data concerning the actual horse-power that is available for climbing hills, and yet they still have for the most part to content themselves with such information as they can get concerning the power which the engine proved itself capable of developing before it was fitted to the chassis. This is, of course, not what they really want to know, for it gives no clue to the efficiency of the transmission gear, and to the free running of the various parts between the engine and the road wheels. Further than this, it would be an enormous convenience to motorists if they could now and again have the power of their cars tested, to see whether they are pulling as well as they should, and it has long been recognised that there is no reason why suitable machines should not be installed in a few of the larger towns throughout the country, to enable this much-needed information to be obtained by anyone. One of the chief merits of such tests of complete vehicles, is that they could be carried out in a comparatively short time, and would not involve taking the car to pieces in any way. Testing plants of a similar character have for some time been in use in the large locomotive shops, and similar works where traction-engines are built, but we only know of one or two automobile builders who have such an apparatus available, even for their own use, and these are intended more for testing heavy commercial vehicles.

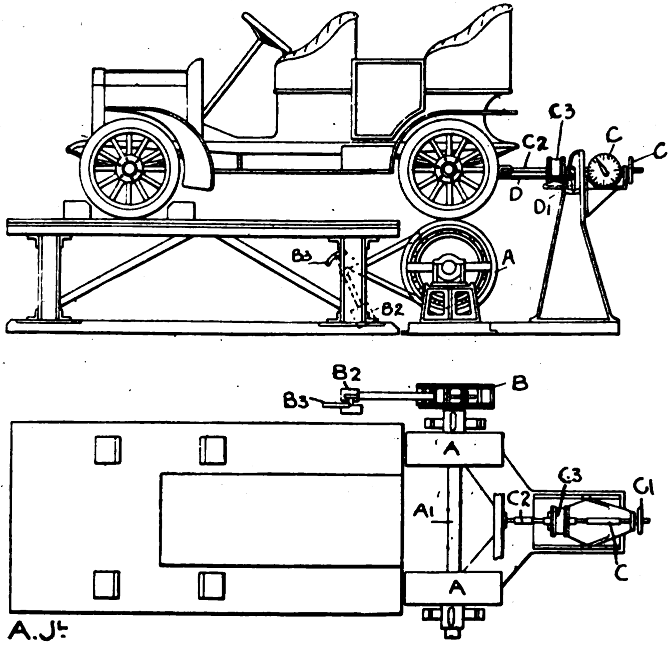


Fig. 1.—Side elevation and plan of the Testing Plant for Automobiles at the Purdue University, Lafayette, U.S.A. In the upper illustration a car is shown in place, ready to have the h.p. on the road-wheels measured.

An U.S.A. University Forestalls the A.C.G.B.I.

It is, we believe, pretty generally known to our readers that the Automobile Club have for some time had such a machine in hand for testing all ordinary types of pleasure vehicle, and now and again official references have been made to it which lead to the hope that sooner or later it will mature in a concrete form. Meanwhile, however, more speedy progress has been made in this direction in America, and such a testing plant is now installed in the Purdue University at Lafayette, Indiana, U.S.A. This machine is constructed on similar lines to those used in locomotive works, and is, we believe, more or less identical with that which the A.C.G.B.I. have in hand over here. The following particulars, which we are now able to give with a few general illustrations, will therefore doubtless prove interesting to a large number of our readers. As will be recognised, there is no real difficulty in constructing a machine of this kind, while, further than this, it is quite a straightforward job to operate it properly and to obtain reliable readings showing the actual power of the car.

A Few Elementary Facts Concerning H.P.

By way of brief preliminary explanation for those who are insufficiently acquainted with mechanics to understand what the term "horse-power" really implies, it may be a convenience if we give a few words by way of explanation.

"Horse-power" is a convenient unit indicating a definite *rate* at which work is being done, and is usually expressed as being equivalent to 33,000 foot-pounds per minute. As applied to a car, therefore, if we know what is the pull (in pounds) that is exerted by the driving tyres on the road surface, as also the speed (in feet per minute) at which the car is travelling, we can then calculate the foot-pounds per minute by simply multiplying these two figures together, and can consequently then ascertain the horse-power by dividing that result by 33,000. It might also serve to elucidate the matters that are to follow in the minds of non-technical motorists, if we were to draw their attention at the same time to the fact that in the testing apparatus we are about to describe, the same conditions are obtained as if the car were propelling itself along a road, although, as a matter of fact, the car itself happens to be held stationary and it is the "road"—an "endless road"—that is propelled backwards by the car instead.

General Construction and Action.

In Fig. 1 the complete apparatus is shown diagrammatically from the side and from above, a car being shown in place in the former illustration. Here it will be observed that the car has been hauled up upon an elevated platform, and has been drawn rearwardly, so that its driving-wheels rest upon two large pulleys, A, which are mounted upon a substantial shaft, A^1. These pulleys and their shaft are free to revolve in large bearings fixed to the floor, and it is the pulleys, A, that represent the revolving and endless road surface. If, when in this position, the car is driven in the usual way, the effect would be for it to run forward, *or* for the rear wheels to drive the pulleys, A, round backwards. The car is, however, prevented from going forwards by means

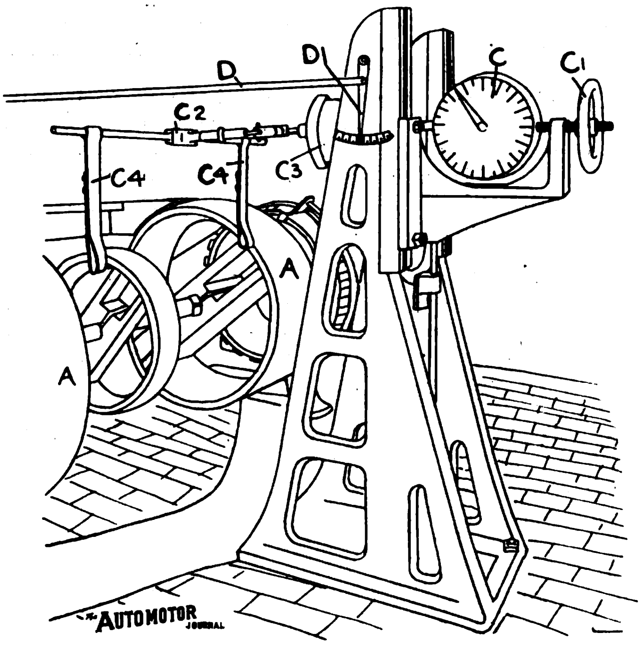

Fig. 2.—The indicating portion of the Purdue University Testing Plant, showing the spring-balance dynamometer, C, with its adjustment-wheel, C^1, draw-bar, C^2, dash-pot, C^3, and attachment-straps, C^4. Also visible are the large pulleys, A, which act as the "endless road" that is propelled by the car.

of a flexible bar, C^2, which ties it to a portion of the apparatus that is rigidly fixed to the floor, but between the bar, C^2, and the solid framework through which it passes is introduced a spring balance, C, that indicates the precise pull upon the bar. The car, when driven, can thus only drive the pulleys, A, and cannot itself move, while the force with which it tends to go forward is at all times indicated by the spring-balance.

As long as the pulleys, A, are quite free to revolve, only comparatively little power will be required of the engine, but it will be noticed that a large brake-drum, B, is also fixed to the shaft, A^1, and that this is surrounded by a powerful brake that can be tightened up to the required extent by means of a hand-screw, B^1.

The more the brake is tightened, the more power will the engine be called upon to give, and simultaneously the higher will be the reading upon the spring-balance, C. Thus, all the necessary data is rendered available for ascertaining the actual horse-power exerted by the car as a whole, for it is only necessary to note the speed of the pulleys, A, and the draw-bar-pull, as shown by the spring-balance, C, in order to arrive at the rate at which work is being done—the foot pounds per minute. Assuming, for instance, that the spring-balance were to read 300 lbs., and that the peripheral speed of the pulleys, A, was 1,760 ft. per minute (20 miles per hour) —*i.e.* 220 revs. per mim., with pulleys 8 ft. in circumference—then by multiplying these together we should have 528,000 foot lbs. per minute, and by dividing by 33,000 we should arrive at the actual horse-power—16 b.h.p. It will readily be understood that tightening the brake-band about the drum, B, is equivalent to increasing the steepness of a hill when the car is running in the ordinary way on the road, and that since any required degree of tightness can be obtained, so that the maximum horse-power can be measured on each of the "speeds" provided by the gear-box, and at any required engine-speeds.

Some Constructional Details.

Considering now the testing apparatus itself in somewhat greater detail, it will be noticed that straps, C^4, are fitted to a cross-member of the flexible bar, C^2, for the purpose of attachment to the back-axle, or the framework of the vehicle, while further provision is made by which the rear-wheels of the car can be kept immediately above the centre of the pulleys, A, by means of the hand-wheel, C^1, just behind the spring-balance, C. There is, too, a small indicating pointer, D^1, conveniently placed for the observation of the operator, this pointer being controlled by a rigid rod, D, that is also attached at its forward end to the vehicle. By tightening or slackening the wheel, C^1, he is always enabled to keep the car in the desired position, *i.e.*, to keep the pointer, D^1, in the centre of its graduated quadrant. These portions of the mechanism are best shown in Fig. 2, where two other small constructional details are also rendered evident. We refer to the arrangements that are made for bodily raising or lowering the spring-balance, C, with its attachment-rod, C^2, and hand-wheel, C^1, to suit the particular vehicle which is being tested, and to the dash-pot arrangement, C^3, which is introduced between the spring-balance and its draw-bar, in order to absorb all vibrations and give a steady reading on the dial, C.

The brake on the shaft, A^1, is prominent in Fig. 4, where it will be seen that the brake-drum, B, is so shaped internally that it can be kept cool by a constant

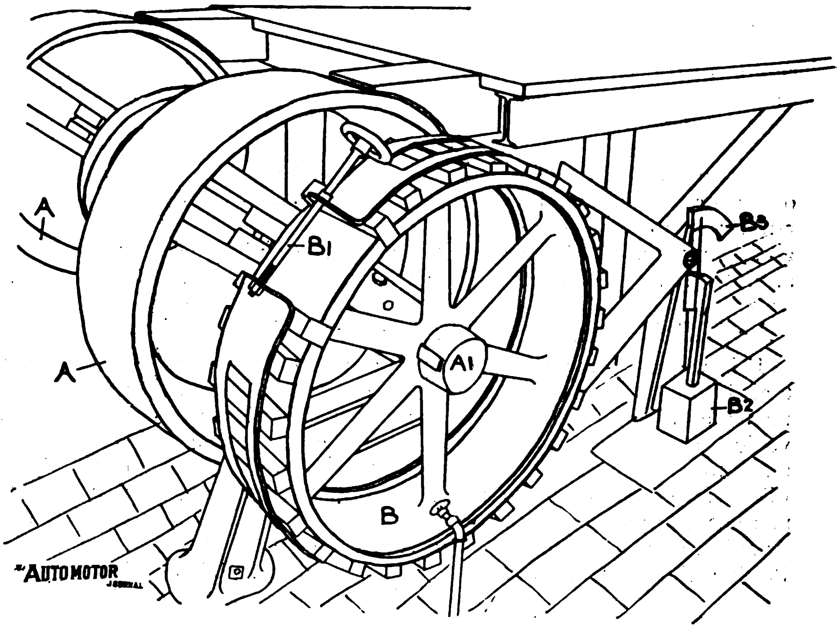

Fig. 3.—View of the adjustable brake of the Purdue University Testing Plant; the water-cooled brake-drum, B, is fixed to the same shaft (A^1) as the large pulleys, A, upon which the driving wheels of the car are supported.

stream of water, and that the adjustable brake-band is furnished with a device for showing the pull upon it, so that a direct reading of the b.h.p. on the shaft, A^1, can be taken from the scale, B^3. The counter-weight, B^2, forms a part of this apparatus, which is combined with the "anchorage" that prevents the brake-band from rotating.

The Modus Operandi.

When using this apparatus, the car is hauled up an inclined plane on to the platform—being either driven backwards by its own power, or being hauled up by pulleys—and after having been attached in the manner already described, safety blocks are placed on each side of the front wheels, purely as a precaution. The car itself is then operated by the driver from the seat in the usual manner. It can be loaded or not with passengers or with ballast, and can, in fact, be driven under almost precisely the same conditions as those under which it works in practice on the road, the b.h.p. on the road wheels being measured on each speed, and with any desired "load" upon the engine. In the Purdue University laboratory a motor-driven fan is used for forcing air at the usual rate of travel against the radiator in the front of the car, and another independent fan is connected up by piping, for getting rid of the exhaust gases that issue from the silencer and delivering them outside the test shop into the atmosphere.

Concluding Remarks.

Such, then, is the apparatus now installed in one of the go-ahead American Universities, and we think that sufficient has been said to show the comparative simplicity of such a plant, as also its undoubted utility. In the main, it is identical with those that have been used in the past for other purposes, and it may also be taken as being similar in general respects to other automobile testing machines that are in course of construction.

Any such machine is naturally too expensive and occupies too much room to be fitted in most public or private garages, but it is sincerely to be hoped that such machines will come into general use before long in this country.

From many points of view it would, we think, be a distinct improvement to substitute a dynamo for the mechanical brake that is generally employed, and thus to absorb the power in a more cleanly manner than is possible when merely dissipating the heat generated in a brake mechanism. An electrical plant of this kind is far more satisfactory from every point of view, even though it costs more money in the first instance, for, in addition to the advantages already mentioned, it is easier to make accurate adjustments and to maintain a constant "load" when the power is converted into electric energy instead of into heat.

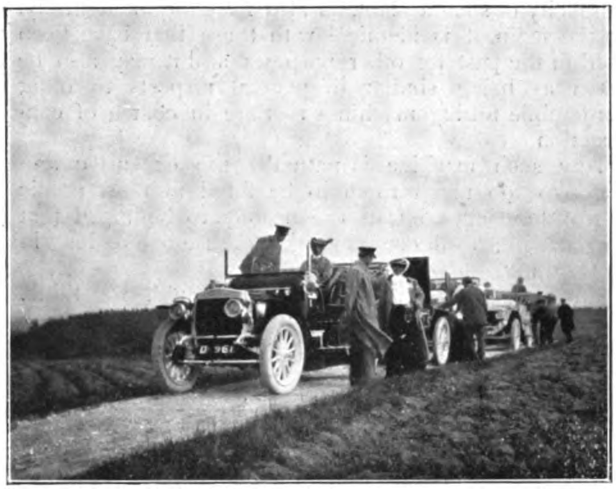
A TRY FOR THE HERKOMER TROPHY.*

By Mrs. Edward Manville.



A TRY FOR THE HERKOMER TROPHY.—
A halt on the journey to Munich, at the top of the Black Forest (1).

I FEEL most awfully nervous, I don't think I ever felt so nervous in my life before. Competing for the Herkomer Trophy did not take half the pluck that it does to tell you about it.

The reason I find myself in this sorry plight is because I want to be a good example; I want to persuade members of our club to go in for competitions, because I most truly believe the very fact of women like ourselves going in for competitions is the best possible thing for the sport, and if they do, I want them to tell us all about it.

My husband and I went in for the Trophy just for fun; we had decided to take our holiday in a motor car in Southern Germany and the Austrian Tyrol in August of last year, and so when we heard that the Trophy was to be competed for in that very district at the very time we should be there we thought it would be fun to compete.

I put it to my husband, diffidently, that it would be impossible for us both to compete in the same car, and, being the delightful husband that he is, he immediately saw my point, and decided I should drive a car just the same as his—a 35-h.p. Daimler.

From the moment that we entered positively tons of literature in German, of which language I do not understand a word, kept arriving at the house. Half of it addressed to "Hochwohlgeboren Herr Maud Manville," and it was quite a long time before we got the secretary of the Bavarian Automobile Club to realise that there was no Herr Maud Manville, only a Frau.

We understood enough to gather that the competition was in four parts. First, an exhibition at which marks were given for appearance, carrossie, and accessibility of parts. Then a hill climb, then a flat race, and then a three days' reliability tour of about 650 miles.

Some friends heard we were going, and decided to join us, so that in all we were five cars, strangely enough all Daimlers. The other four were entered by husbands of our members—Mr. Dawson, Mr. Rendle, Mr. Herdman Ash, and my husband.

You will not be able to see the five cars very well on this slide, but it will give you a sort of general idea of our caravan.

I have only two photographs to show you of our trip to Munich, the centre from which the competition was organised; the truth is that we were eager for the fray, and our one idea was to get on, so we hurried on by the direct road by Rheims, Nancy and Strasbourg. Indeed, many times our run quite partook of the nature of a race, and it was quite fun to see the way the inhabitants of the little villages realised this, and urged and encouraged on the car that happened to be running last.

Only once did we leave the direct road, and that was because we wanted to do a really big hill climb, to see how the cars were running.

We went over one of the most beautiful mountain roads in the Black Forest, and really did a terrible climb.

When we got to the top we felt very happy; our cars had done splendidly. We had got up at six, and now it was only ten, and we had time and appetites for breakfast. However, the dismay of the housewife of the little inn was rather great, when fifteen of us, for we were that number, including the drivers, demanded breakfast immediately, and she knew that her only breakfast was very German sausage and eggs, and the utensils she had only permitted of two eggs being cooked at the same time. You can imagine it took us some time to get our hunger satisfied, and that there was leisure to take this photograph. (Fig. 1.)

We only got to Munich two or three days before the competition, and we had all we could do to get our cars cleaned up and thoroughly examined before the Exhibition.

We were most kindly received by Professor von Herkomer and the representatives of the Bavarian Club, who did their best to explain the tremendous number of rules of the competition to us.

We found that we must, of course, each carry a controller, that only one person would be allowed to touch the engine during the three days of reliability, and that a second man might be carried for tyres; so that filled the car, the driver, the controller, and two men. Our cars were kept in the Exhibition till six on the Friday night, and then we found we had to go 40 miles to the scene of the hill climb. This was rather a nasty knock, because it meant that we should have no chance of trying the hill, and we heard that several professionals had been practising on it for weeks. However, we had to trust to luck. We did not get to Kochel, the village at the foot of the hill, till nine that night, when it was raining cats and dogs, and therefore impossible to try a strange hill. We heard, however, that we might do so between six and seven the next morning, so we all turned out, but we found it impossible to really get up any speed on the hill because all the other seventy-nine competitors were trying it too, and there seemed to be an unending stream of wagons with German beer, and char-à-bancs with people who were going to drink the beer, going up to take up their positions for the day. Of course, we saw what it was like, found that the gradient was really nothing, but the bends appalling and very frequent, and seeing that it was still pouring with rain, or rather a sort of wet mist which makes the roads worse than anything else, the going was likely to be as bad and skiddy as it possibly could be.

Everyone was searching for non-skids, the racing cars had one on each wheel. The men of our party all took upon themselves to warn me most seriously about not taking any risks. There was no necessity to go fast or tear round the corners, as, after all, the hill-climb meant very little. But I was wild when I found that they did not act on their own good advice at all, with the result that two of my party beat my time.

When I took up my position to start the hill-climb (3), flying a Union Jack, I got a tremendous reception, and I realised then for the first time the sort of reception I was going to get right through the competition, and I may say that that reception has been going on ever since.

Only the other day, when I was in Cairo, my husband and I noticed that the waiter at our table was particularly attentive and impressive in his attentions. One day I asked him if he had ever waited on us before, and he said with a sweeping bow, "Madame, did I not see you drive into Baden-Baden?"

I was rather afraid I should not get a good start. The language

A TRY FOR THE HERKOMER TROPHY.—

---

* A paper by Mrs. Edward Manville, read before the Ladies' Automobile Club of Great Britain and Ireland on Feb. 22nd.

Mrs. Edward Manville starting on her Daimler car for the Hill Climb (3).

Mrs. Manville waiting the word to go in the Flat Race in the Förstenrieder Park, in which she accomplished the **fastest time of the day (5).**

A TRY FOR THE HERKOMER TROPHY.

was different, and I did not know what the method would be; but it was perfect. It seemed ages going up the hill. I felt I had been driving up it for years, although it was only 3½ miles long, and only took just over seven minutes. The first thing that cheered me up was that just in the last straight piece I caught up a car that had started two minutes ahead of me.

I think the best cheers I got were from the Royal party, who sat all day in the rain watching the cars. The German Emperor's sister, the Princess of Saxe-Meningen, was herself there all the time, and was deeply interested, she told me afterwards.

After our climb we had to run down the hill the other side, where the cars were all collected by the Walchensee, and we had lunch at the inn there (2). From that moment we started on a career of veal, which lasted for four days. The German idea of supporting the inner man in times of stress is evidently veal.

Next morning we found that my car was fifth of all the cars, my husband's second, Mr. Rendel's third.

Next day was the flat race. It was a perfectly glorious morning, and I knew everything was bound to go right on such a day, and determined to listen to no more good advice.

The race was to take place in a sort of private park; it was nearly four miles long, and the surface perfect.

There were two bends in it, which, although they seemed nothing going at an ordinary pace, became pretty hard to get round at 78 miles an hour.

At the same time as the race for the Herkomer Trophy, there was a race run for racing cars for the Bleichroder Cup, and, funnily enough, the car numbered twelve won the Bleichroder Cup (4), and the car numbered twelve won the Herkomer Trophy.

You will see this car just starting in the flat race (4a). A 40-h.p. Mercedes, driven by Mr. Ladenburg. He was a very nice boy, and he made a very nice picture, I hear; for not only did Professor Von Herkomer give the trophy, but he painted the picture of the winner.

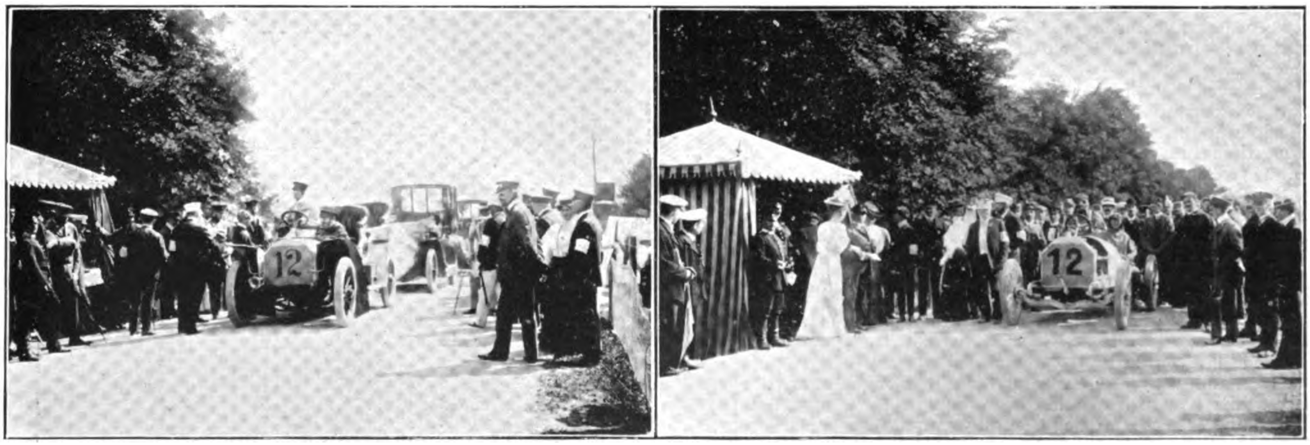
I had only driven over the road once, in the dark, and felt a little anxious about the bends; but what really looked like a bit of very bad luck turned out to be the very best of luck for me.

The bad luck was that the car ahead of me was so slow that, though it had started two minutes before me, I caught it up within the first two miles, and I could not make the driver hear that I was behind and wished to pass, and the people would crowd so on to the road that I dared not attempt to do so. I was heart-broken. I had intended to make such a splash, and here was my chance absolutely gone. Later I got a message that the judges and the Royalties had seen my dilemma, and wished me to have another run (5). So in that way I had a rehearsal, which stood me in very good stead; for, as a matter of fact, when I made my second run, I beat absolutely everybody else by quite a good deal.

My husband came second, then Mr. Rendel, then Mr. Dawson, and after the four English cars only came all the others.

On Monday morning, at 3.30, we had to be in our places for the Reliability Trial. I need not explain that it was impossible to take a photograph of the start. It was really most dreary—dark and awfully cold. However, a beautiful sunrise soon changed all that, and I was beginning to feel that the most delightful thing in the world was a reliability trial, when suddenly I had my first tyre trouble, and that meant I was absolutely out of the Trophy. The penalty for punctures was very severe, and, besides that, there were sure to be lots of cars that would go through without any, so that it was quite certain that one loss of marks such as I had would put me out.

We ran about 20 miles between controls, and had to do the distance in about an hour and a quarter or an hour and a half. The



A TRY FOR THE HERKOMER TROPHY.—Herr Ladenburg on his 40-h.p. Mercedes, the winner of the Herkomer Trophy for Tourist Cars (4a on the left), and on the right (4) Hieronymus on his 90-h.p. Mercedes, the winner of the Bleichröder Cup for Racing Cars. Both cars, it will be seen, by a coincidence, bore the number 12.

A TRY FOR THE HERKOMER TROPHY.—Mrs. Manville's arrival in Munich at the end of the Reliability Trial, when the front of her car was almost smothered by a huge laurel wreath (6).

fact was that everybody went pretty fast at first, and then had to while away time just outside the controls.

Quite towards the end of the day, as we were nearing Baden-Baden, our stopping place for that night, we passed a big hotel, where there were a number of people waiting for the cars, and there I saw three great big Germans, with the proper sort of scars all over their faces, standing with three glasses. They called out to me to stop. I asked my controller's permission, which he gave—I expect he saw the glasses—and then these men came up to me and said they had been waiting and watching for me to come, and had each of them got a drink, one beer, one wine, and one milk to offer for my refreshment. I took the milk most gladly, and suggested that my controller would enjoy the beer. That day's run was 250 miles.

We had to lock up the cars at night in the presence of the controller, and we were allowed half an hour in the morning to get the cars ready for the day, again in the presence of the controller. To do this was quite hard work in half an hour. One man oiled the engine and the other filled up with petrol, which took all the time, because everybody was scrambling for petrol at the same moment, so I filled up with water and dusted the seats, &c., myself.

Next day it was quite an early start, 5 a.m. and just daylight. A most beautiful rosy sunrise greeted us as we climbed the hills out of Baden-Baden. As the day wore on it got very hot, and by the time we stopped for lunch there was such a scorching sun that we had to get hold of anything we could in the way of covers to protect our tyres. After lunch I was running in front of my husband, who was then first favourite for the Trophy, and how I was hoping he would get through all right. You can imagine my distress when I heard his tyre go. I felt absolutely sick, and turned to my controller and said, "Please may I stop and cry?" He gave me a severe look, and said, "No, go on," and then he began turning over the pages of his enormous book of instructions as fast as he could, to see if there was any rule for drivers who wanted to stop and cry, but found none. After about five minutes' meditation, at my request, he turned and said to me, "You may go to your husband;" but then I didn't want to—there was really nothing to be done.

We stayed that night at Nuremburg, having done 240 miles that day. Next morning we were warned to go slowly, and in any case I had never run very fast, as I felt my car had vindicated itself as being the fastest car, and there was no need to put any extra strain on the tyres.

But often my controller was annoyed that other cars passed us; he wanted to realise all the time that he *was* on the fastest car, and after we left Nuremburg he began to urge me to go faster. He said "We will pass that car," but I said, "Oh, no; we do not want to pass." "Oh, yes; I will not take his dust." "But," I urged, "if we pass him we shall get somebody else's dust." "Well, we will pass him." Then I used my last argument: "Oh, but we can't; he is a Prince." "Prince of no land, go on," said he.

At the last control Professor Von Herkomer was waiting to greet the cars, and, with his usual happy knack, managed to say the very nicest thing he possibly could to everyone.

Running into the Munich Control was quite an ordeal—ever so many Royalties were collected there—and when I made my appearance the people cheered, a band played our National Anthem, and the club presented me with a most magnificent laurel wreath about 6 ft. in diameter, and tied up with Bavarian ribbons (6). The Princes all congratulated me, and were most kind in all they said, and I was only too glad to be able to say how wonderful I thought the management and organisation of the whole thing had been.

The next day we were all invited to the Palace of Prince Ludwig of Bavaria, and I was presented to the Princess and to him, and he then made a point that I should go to the banquet which was to be given that night to the owners and drivers of the cars. I had had no intention of going. Just imagine being the only woman among 270 men; but I could not get out of it after Prince Ludwig's request, so I took my courage in both hands and went.

I wonder if any of you have ever been to a German banquet—it is so funny. The speeches come between the courses, so that it takes a very long time to get along with the dinner, and, as a matter of fact, lobster salad was handed at ten, and at a quarter past eleven, when I left, the part I am interested in, sweets and dessert, had not yet made their appearance.

It was hors d'œuvres, then a toast to the German Emperor, soup, Prince Henry of Prussia, fish, and to my horror, Mrs. Manville. I wondered what I was to do to acknowledge it, my husband was ever so far away, but Prince Ludwig himself solved my difficulty by "prosting" with me, that is clinking glasses, immediately after my health had been drunk. Then every man in the room did likewise. The beautiful menu, designed by Professor Von Herkomer, you see on the slide, showing the Future bound to an automobile.

Now that the Trophy was run for and won, we were at liberty to explore the beautiful country lying south, which, as a matter of fact, happens to be part of the road for this year's course. You will see Hochfünstermintz in the Unter Engadine (7) on my slide, and the next one shows the road leading along the Inn to Landeck (8) along which we had to go to climb the Vorarlburg Pass. This pass is the one on the Paris-Vienna road, over which the Gordon-Bennett Race was run, which Mr. Edge won, and it was here that one of the drivers—Hemery, I think—drove right over the side and toppled down, without doing himself any harm, but the car was badly damaged. Right on the top of the Vorarlburg Pass there is a monastery where we went for milk, and paid a visit to the little chapel, which is dedicated to St. Christopher, very appropriately, as St. Christopher, as you all probably know, is considered in France the patron saint of automobilists.

The roads were most picturesque, very good surface, and beautifully engineered; you will see the tunnels right through the mountains (9).

A TRY FOR THE HERKOMER TROPHY.—Hochfunstermintz in the Lower Engadine (7).

Being free-lances in our good motor cars, we were able to dodge about the country as we liked, and, hearing the play was on at Oberammergau (10), we decided to go there. We made a most romantic entry to the little village. We did not get there until about midnight. The road is very winding and mountainous, and every time we turned a corner it seemed as if the mountains shut up behind us as we went into the heart of the world where no one could follow us. The most beautiful moon was shining, and by its light we could see everything perfectly. Up and up we went, wondering when we should reach the wonderful little town. But we knew when we had got there, for suddenly a big crucifix was to be seen by the roadside, and, seeing it, we felt quite certain that we had reached our destination.

Near Oberammergau there is a wonderful monastery at Ettal (frontispiece), which is most interesting. It has a beautiful ceiling in the church, interesting relics of martyrs, and *such* a view out of the gateway, looking towards Oberammergau, and taking in the wonderful crucifix on the top of the mountain which overshadows that place, and which is so enormous that no one can imagine however it was got there.

Of course, we had no end of frontiers (frontispiece) to pass with all this dodging about, and it was often a difficult problem for the officials to find enough money to pay us off as we left a country. On one occasion it could not be managed, and I do not know exactly what he had to do; but the gendarme took us to another place where he got the money. He dare not leave the cars till they had passed the frontier, where stood the man with the gun, so went two miles with us to the next country and waited to see us over the boundary, and then had to walk two miles back in the pouring rain. At another frontier we had a funny experience of red tape. My husband happened to stop his car with the two front wheels in Germany and the two back ones in Switzerland, and the officials would have nothing to say to him until he had backed the whole car into Switzerland. You will see the gendarme directing the operation.

When we crossed the Austrian frontier we found ourselves in the country of "langsam." It was the only place where we saw the people really in costume, and most picturesque it was to see them on their bicycles and walking in their green leather clothes, and pleasant to hear them yodelling to us in a friendly way.

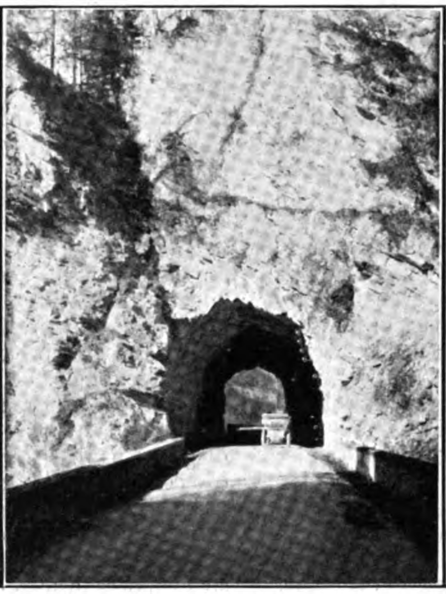
We spent very little time in Switzerland, and that in the southern part, and were principally interested there in the strange wooden-covered bridges, one of which you will see on this slide; the next will show you a view of the bridge taken from a hill above.

We wanted to go to see the falls of the Rhine at Schaffhausen, and after that we made a bee line for England, having enjoyed every bit of the tour. There was only one crumpled rose leaf in the seat of my car, and that was that the Trophy was not in the back.

The photograph will give you some sort of idea of the beauty of the Trophy, but of its making and its meaning I do not mean to tell you anything, as Professor Von Herkomer is here and has been good enough to say he will tell you himself.

He took enormous pains over the whole thing, not only over the Trophy, but over the organisation and actual carrying out of the competition itself and in the competitors, proving himself, if possible, as great a sportsman as he is an artist.

Along the Inn to Landeck, the road to the Vorarlburg Pass (8).



A tunnel on the road from the Lower Engadine towards Landeck (9).

Oberammergau (10).

A TRY FOR THE HERKOMER TROPHY.

Hard Swearing.

A fine sample of police prosecution—or persecution, take it which way you will—was provided recently at Highgate when a motor 'bus conductor was declared by a policeman to have been intoxicated while in charge of his 'bus. When he was brought in even the police surgeon said he was sober, but the prosecuting policeman still maintained that he was drunk while on duty, and perversely got sober on his way to the police station—a very useful art, no doubt, for those who can acquire it. It so happened, however, that the magistrate's clerk was on the 'bus at the time, and maintained that the conductor was not drunk, so the charge was dismissed. It is to be hoped that with the new ordinances which are to be issued by the new Government for the police, we shall see less of this scandalously unfair style of prosecution.

Motor Car Paper at Liverpool.

On Wednesday of last week an interesting paper was read before the Liverpool Engineering Society by Mr. Ernest A. Rosenheim, B.Sc., entitled "Motor Car Practice in 1905," the president, Mr. J. Reney Smith, M.I.M.E., M.I.N.A., occupying the chair. The paper was of a comprehensive character, embracing the chief constructional tendencies of petrol car construction, and was illustrated with a considerable number of photographic reproductions and drawings—most of which were placed at Mr. Rosenheim's disposal by The Automotor Journal. A considerable amount of attention was devoted to the subject of ignition, magneto systems being referred to at no small length. Carburettors were also dealt with in some detail, and Mr. Rosenheim referred to the strong reasons that there are for striving to use heavier or cheaper fuels than petrol.

THE MULTI-CYLINDER QUESTION.

On pages 71 and 72, in The Automotor Journal of January 20th last, an attempt was made to show the real relative merits of engines having 1, 4, or 6 cylinders from the point of view of steadiness of running and of inherent flexibility—steadiness of running owing to the evenness of the torque (twisting strain on the crank-shaft), and flexibility owing to the non-requirement of a heavy fly-wheel. Probably the most striking point then brought before the notice of our readers was that the "torque" on the crank-shaft of a petrol engine is affected to an enormous extent by the weight of the reciprocating parts, and that the strains which are set up by starting the pistons from rest immediately after each dead-centre, and by bringing the pistons to a standstill at each dead-centre, are of very considerable intensity, even in comparison with those set up by the great changes of pressure that act upon the pistons in the combustion-chambers.

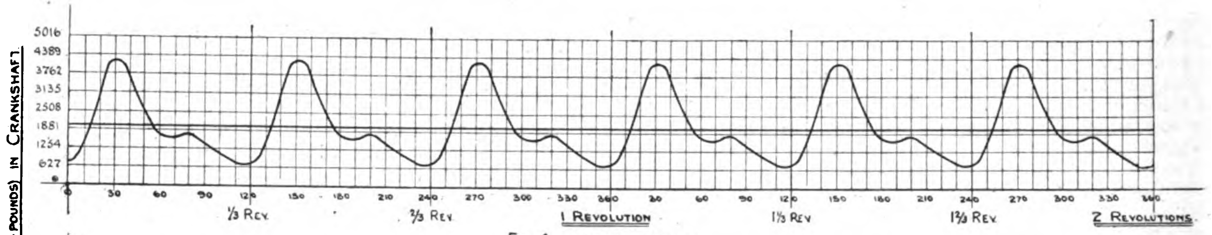


Fig. 4. Six cylinder engine.

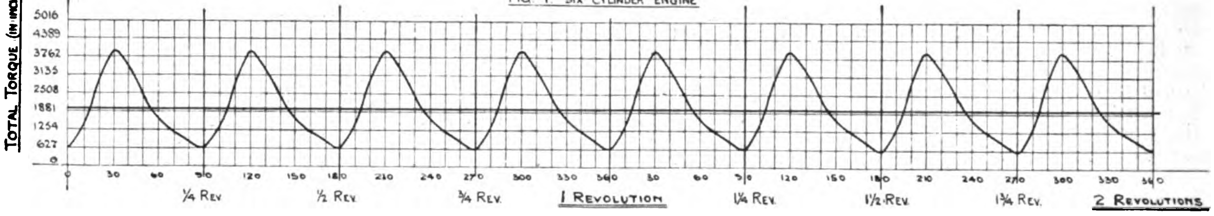

Fig 6. Eight cylinder engine.

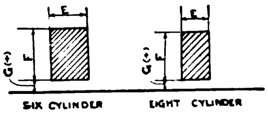
The diagrams that we then published, in order to demonstrate these facts in a graphic manner, were, it will be remembered, prepared by Mr. S. F. Edge, and were based on data obtained by him from a 6-cylinder Napier engine of 4-in. bore by 4-in. stroke—an engine having unusually light pistons and connecting-rods. They, moreover, only referred to engines having one cylinder, four cylinders, and six cylinders, and did not include corresponding curves for those having eight cylinders. Now, however, Mr. Edge has supplemented his previous work by sending us a comparative torque-diagram for an 8-cylinder engine of similar power, and this we now reproduce to the same scale as before, together with the 6-cylinder diagram. Accompanying them are our own rectangular diagrams, which sum up in a simpler form the three main points that are deducable from the more comprehensive curves.

As would be expected, the diagrams which we now publish show that the length of time which intervenes between the impulses (the dimension E) is less with an 8-cylinder engine than with a 6-cylinder engine, and that the extent to which the torque varies (the dimension F), is also less with the engine that has the greater number of cylinders. It will, however, come quite as a surprise to many motorists to notice that the torque actually falls to a slightly lower degree on the 8-cylinder crank-shaft than it ever does on the shaft of the 6-cylinder engine. This practically means that the 8-cylinder engine requires a slightly heavier fly-wheel, in relation to the 6-cylinder, than would at first sight be anticipated, and certainly appears to bear out Mr. Edge's contention that it is quite consistent to be an advocate of 6-cylinder construction without being in favour of merely multiplying the number of cylinders indefinitely.

Fig. 5. Diagrammatic Summary showing relative theoretical merits of 6 & 8 cylinders.

Explanation.

E = Interval between impulses.
F = Unevenness of torque.
G(+) = Absence of dead centre.



What is apparently demonstrated by our present diagrams is that for engines of a certain power, at any rate, there is no such material gain in going a stage further (adopting eight cylinders) as there is in employing six cylinders instead of four. It is, of course, quite true that more cylinders lead to greater steadiness of running, and that, for engines of the same power, higher speeds can be obtained in consequence of the reduced weight of the reciprocating parts, but as regards any very strong merits of special character affecting one particular type of engine as against another, six is evidently the highest number to attain which it is worth while making any real sacrifice—such as prime cost, risk of trouble, &c. Primarily, however, the number of cylinders is bound, in the future, to depend on the amount of power required, and upon the speed at which the engine has to run.

An American "Motor Way."

In the United States a "motor way" is projected by Mr. J. Brisbane Walker, working with the A.C. of America, from New York to Philadelphia. The suggestion is that it should be 82 feet wide, divided into six sections, three for each way. These are respectively to be used by (1) slow motor vehicles, (2) those travelling at 30 m.p.h., and (3) high speed machines.

Manchester Exhibition.

At St. James's Hall, Manchester, a fine display of motor vehicles has been brought together under the guidance of Mr. Walter Cawood, working on behalf of the Motor Trades Association. The attendance of the public has been very great during the week, the close taking place to-night (Saturday).

CORRESPONDENCE.

. *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion, or containing queries.*

FOUR-CYLINDER AND SIX-CYLINDER CARS.

To the Editor of The Automotor Journal.

Sir,—With regard to this much-debated question of the relative merits of four and six cylinders (especially in connection with petrol consumption and wear and tear of tyres), and the proposed competitions between four and six-cylinders, I have been interested to watch the varying phases. I have taken the trouble to analyse the correspondence that has appeared in connection with it, and must say there has been a tremendous amount of talk for a very small result.

On December 2nd, in reply to criticism as to petrol consumption in 6-cylinder cars, Mr. Edge challenged Mr. Jarrott to do battle between two 40-h.p. cars, the suggestion being that Mr. Jarrott should run a 40-h.p. 4-cylinder De Dietrich against a 40-h.p. 6-cylinder Napier. He suggested that the two cars should keep together and be tested under identical road conditions, and Mr. Edge offered to run weighted chassis if more convenient for Mr. Jarrott. Mr. Edge mentioned that, failing Mr. Jarrott accepting the test, he would run a 6-cylinder Napier under club auspices, which, I believe, he has since done. Mr. Jarrott accepted the challenge with modifications, preferring to run a 40-h p. Crossley instead of the foreign-made car. I may have missed it, but I have not heard anything more in connection with this proposed match.

The next thing that happened was that Mr. Arnott wrote urging the advocates of the two types to compete; then came Capt. Deasy on the scene, challenging all and sundry 6-cylinder cars to race over a distance, say, of 100 miles. By his letter, Capt. Deasy seemed anxious to back the business both ways. This drew an acceptance from Mr. S. F. Edge, he accepting the challenge for a 6-cylinder Napier car against a foreign 4-cylinder, and offering to cross to the Continent with Capt. Deasy to decide it. At the same time, Mr. C. Johnson wrote accepting Capt. Deasy's challenge, but making it a "perfection" trial.

Following this, Capt. Deasy wrote as to the two possible acceptances, but objecting to both, to Mr. Edge's because his car was too fast, and to Mr. C. Johnson's because his tests were too comprehensive, and gave his own ideas of suitable conditions.

A great number of people are interested in this matter, and it seems a pity something absolutely definite cannot be arranged. With this end in view, I have sketched out below conditions that would settle the points at issue.

Test to be over a 100 (?) miles of give-and-take road. Points to be inquired into:—

1. Horse-power, say 40.
2. Minimum number of revolutions of engine per minute, car standing.
3. Maximum number ditto.
4. Slow running of car on top gear, clutch not slipping.
5. Fastest speed on the same gear.
6. Ability to take hills on same top gear.
7. Silence when running on top gear.
8. Cars to be of the same total weight: differences to be made up by ballast.
9. Cars to run between two observing cars about 100 yards apart.
10. Petrol consumption to be taken.
11. Engine to run all the time, and not allowed to be switched off going down hill.

G. S.

South Ealing, Feb. 21st.

To the Editor of The Automotor Journal.

Sir,—I am very interested indeed in all the correspondence in your valuable paper which relates to the unprecedented superiority of the 6-cylinder car.

I think that to have run a car on top speed from Brighton to Edinburgh, with a consumption of only 18 miles to the gallon, would have been such a feat as would have proclaimed for ever the merits of the 6-cylinder principle; but it has not yet been done!

The much lauded performance has had a bad shake up since the publication of the fact that the car in question was geared down by 4 sprocket teeth.

I, for one, am greatly disappointed that the performance should have proved—nothing newer than the fact that even my old 8-12-h.p. Phœnix Panhard, or anybody else's, could have accomplished the same with the greatest ease—if geared low enough!

No doubt the claim of the 6-cylinder car to be wonderfully easy on tyres is again substantiated by the official report of the later trial.

In ending this letter, which I hope may not be encroaching on your valuable space, I may remark that the probability of my old car, minus four sprocket teeth, being able to get up Netherhall Gardens on its top speed is not so remote as some of the disciples of the 6-cylinder car might imagine!

Q.E.D.

February 19th, 1906.

To the Editor of The Automotor Journal.

Sir,—I was very interested to read the letter in your issue of February 24th from Mr. W. M. Letts, who seems to have some queer ideas as to what is required in a touring car. His theory is, apparently, that variation in speed by means of the throttle and sparking-levers is not a thing to be desired. Has your correspondent ever been on an up-to-date motor car? His idea appears to be to provide racing experts with ease, comfort, and simplicity, but to deny the same comforts to the owner of a touring car.

If ever there was a case of "sauce for the goose being sauce for the gander," surely this is one, and I cannot for the life of me see why a racing man, who is an expert, should be coddled, and, at the same time, the ordinary owner be condemned to speed variations obtained by means of a speed lever and frequent use of the clutch. It would be interesting to know from Mr. Letts at what point exactly a flexible engine with delicate throttle and sparking-lever control ceases to be desirable in connection with a touring car. If such is the case, it logically follows that Mr. Coleman's advertisements of his White steam car in the same issue of your paper, in which he claims elasticity and ease of control, are in reality drawbacks to his touring vehicle, though they might conceivably, according to Mr. Letts' theory, be of use in a racing White steam car.

The De Dietrich people claim that their car is like an electric vehicle. We all know the chief points of an electric vehicle to be ease of control and absence of speed-changing mechanism.

With reference to the Crossley car, I find such meaningless phrases, as "engine will be extremely flexible, and it will be possible to drive the car at a slow speed even on top gear," and, "the control of the engine will be secured by two levers on the steering-wheel, one operating the mixture, the other the sparking, whilst at the same time a foot accelerator will be fitted."

Surely Mr. Letts cannot be in touch with current motor matters or he would not have written a letter so contrary to all well known motor advertisements. Captain Deasy, too, I notice, describes his Martini as a beautiful flexible engine, mentions ease of control, and a decelerator pedal giving foot control as a further refinement.

Delaunay-Belleville people, too, speak of the unique flexibility of their engine. The Hotchkiss people also advertise their 4-cylinder cars as "silent and flexible as a 6-cylinder." Surely the firms in these advertisements do not merely refer to their racing cars and not to their touring vehicles; but, according to Mr. Letts, if the remarks do refer to touring vehicles, they are not desirable properties.

It would be interesting to know whether Messrs. Coleman, Delaunay-Belleville, Hotchkiss, and Captain Deasy, &c., look upon these points as desirable in touring vehicles, or whether their advertisements are concerned only with racing cars.

Incidentally, the number of gentlemen who advertise their cars on the same lines, apparently to a misguided public, might be added to almost indefinitely.

Yours truly.

J. Lambert.

PROGRESS AND A GUARANTEE.

To the Editor of The Automotor Journal.

Sir,—The present moment is a particularly interesting time from the British motor manufacturer's point of view. For the first time in the history of the movement the British manufacturers have made in this country far more cars in a month than were imported; the British manufacturers made motor cars during January to the value of not less than £468,000, and this, remember, is made up merely from the principal firms. There are a large number of smaller firms who have not been included. The total imports of foreign cars into Great Britain during the same period was £317,000.

I have been in touch with a very large number of the British firms who state their January outputs are not anything like as large as they have arranged for future months; they are nearly all increasing their factories, therefore, during 1906, there will not be less than five million pounds' worth of motor cars manufactured in this country, and, best of all, nearly all the cars manufactured in Great Britain that go to make up the totals I have given you are made by firms who are making splendid vehicles.

In regard to the Napier, the progress is still extremely satisfactory, and the latest development is that having found from actual experience with a very large number of 6-cylinder Napier cars which have been in the hands of our clients, and have been used and driven under ordinary conditions, that the extraordinary reduction in wear and tear that has made itself evident compared with 4-cylinder cars, enables me to give a guarantee with every 6-cylinder Napier I turn out, to extend over a period of three years from the date of purchase. This, I think you will agree with me, is one of the greatest proofs which can be given of the perfection attained by the Napier principle of using six cylinders, coupled with the world-wide reputation that high-class British workmanship and material has, and it is interesting to note that the foreign manufacturer has never been able to give anything like such a guarantee with his foreign vehicle as is now given with the 6-cylinder Napier.

Yours truly,

Feb. 24th. S. F. EDGE.

BRITISH OUTPUT.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Mr. S. F. Edge made a public statement on the evening of February 24th in respect to the present value of cars manufactured in Great Britain.

While thoroughly in accord with Mr. Edge's endeavour to demonstrate the fact that our home manufacture of motor cars to-day exceeds in value the imports of foreign-made cars, we are entirely unable to understand how Mr. Edge has arrived at his figures.

We may say for ourselves that, when approached on this subject, we declined positively to state the value of our monthly output, but nevertheless gave certain information as to the number of work-people employed and the amount of our weekly wages bill. At the time of asking for this information Mr. Edge sent us certain particulars with regard to the output of various other companies, and we can only say that if Mr. Edge's statement has been based on an assumption from the figures as submitted to us, we think—while making every possible allowance from a patriotic point of view—it would be best to accept these figures with a good deal of reserve.

Yours faithfully,

For THE WOLSELEY TOOL AND MOTOR CAR CO., LTD.,

J. D. SIDDELEY, General Manager.

February 26th, 1906.

THE FLYING PROBLEM.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In answer to Mr. Roe's letter, I understand his model to be 40 ins. long by 6 ins wide, weight 12 ozs., scale $\frac{1}{12}$.

Now, as this model has only one rear rudder, and one front controlling curve, I take it to be a model of the Wrights' last gliding machine, but this only had a length of 32 ft. by 5 ft., weight 108 lbs., so fail to see that it can be to a scale of $\frac{1}{12}$.

Then again, the power flyer, 40 ft. by 6 ft., has two front controlling curves and rear rudders, but as the weight is considerably more than 108 lbs., I do not quite see that it can be a scale model of this.

Like Mr. Roe, I think the success that will be obtained this summer will prove epoch making in the highest degree.

Yours truly,

MICA CAM.

Acton, February 25th.

DETRIMENTAL BRAKES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I think it would not be amiss to call the attention of your readers to the advisability of paying special attention to the methods now universal in driving cars with cardan shafts. It has frequently come to my notice of late that drivers and owners are ignorant of the fact that to use a foot-brake that is connected to the propeller-shaft, or to the projecting shaft from the gear-box, is disastrous and destroys more quickly than anything else the life of the small pinion. As the cardan shaft is now almost universally used, it is more necessary that this explanation would be of help to all motorists, because they have studied and read and learnt mostly from the chain-driven car; and when driving with notable drivers, I have been surprised to see how severely they have used their foot-brake, without considering the effect on the life and the wear and tear of the back-axle; whereas, if side brakes were used when de-clutching, the strain is only distributed on the road wheels, and, generally speaking, the purchase of a hind brake is a third greater than the foot-brake, and the fact must not be overlooked that when the foot-brake is used it is the means of causing a backlash, and a great strain on the differential and the small bevel pinion, which is generally keyed on to the cone of the propeller-shaft.

Yours faithfully,

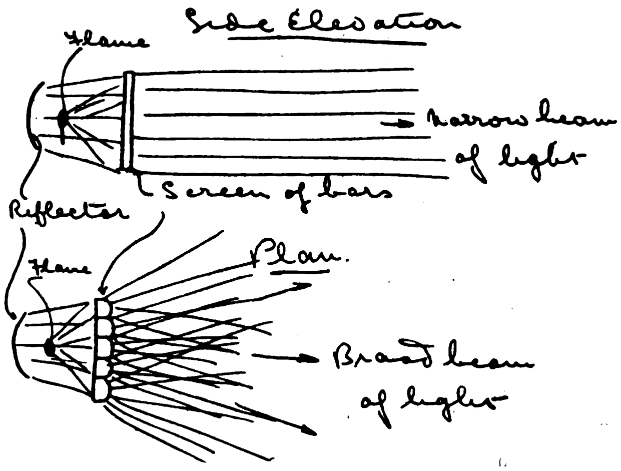
Feb. 23rd. F. F. WELLINGTON.

[The point raised by Mr. Wellington is very similar—although applied to less drastic conditions of working—to that raised in our front editorial paragraphs last week, when we deprecated the suggested employment of the engine as a brake on heavy commercial vehicles.—ED.]

GLARING HEADLIGHTS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Regarding the question of the annoying glare from headlights, I should like to call attention to the practice of marine searchlight makers, when designing searchlights for use on the Suez Canal and for entering harbour where the naked lights would dazzle other shipping. The usual practice is to place a removable screen before the light, made of vertical bars of glass, as shown in sketch. These bars are flat on the side nearest the reflector and convex on the outside, the rays of light being thrown in a narrow and wide band, horizontally. It is quite easy to look at a searchlight so fitted, when only a few feet outside the area of light, although still in the full glare when the screen is removed. This system seems particularly applicable to headlights, as it does not waste somewhere about 50 per cent. of the light, as must occur when frosted half glasses and similar devices are used, but, on the contrary, collects every ray available and throws it right where most needed. The bars, being small and of simple section, would not be expensive to renew in case of breakage, and require no fantastic lenses worth their weight in gold as used at present. Trusting that someone who has had the necessary experience may be coaxed to give us some useful data on the subject.



Yours truly,

Feb. 26th. G. TILGHMAN RICHARDS.

"HONOUR TO WHOM HONOUR IS DUE."

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In the *Standard* of the 22nd inst., it is stated that the original 6-cylinder car was a Spyker, and that this was on exhibition at Paris in 1902, and at the Crystal Palace in 1903.

In the report which appears in the issue of the *Standard* of the 26th inst., concerning the dinner which was given by Mr. Edge on Saturday last, it is stated that I said it was true that a Spyker car with six cylinders had been running before the appearance of the 6-cylinder Napier.

As a matter of fact, on Saturday night I tried to make it clear that so far as I could ascertain the *Standard* was incorrect in stating that the Spyker car was exhibited in Paris in 1902.

Through the courtesy of Mr. Edge, I am able to enclose an extract from shorthand writer's reports on what I said on Saturday night.

This matter is of some interest; I should be glad if you would correct me if I am wrong in stating that the Spyker was not exhibited until December, 1903, whereas the Napier car was running, and its appearance was publicly announced on the 24th October, 1903

With reference to the remarks made by the Birmingham correspondent of the *Standard*, in the issue of the 22nd inst., may I be permitted to state that immediately Capt. Deasy issued his challenge, I wrote accepting it.

I am the first to acknowledge that the credit for introducing the 6-cylinder car rightly belongs to Mr. Napier and Mr. Edge. The Birmingham correspondent has no more right to presume that the 6-cylinder Rolls-Royce car is a copy of the 6-cylinder Napier car than he has to presume that the 4-cylinder Martini car is a copy of the 4-cylinder Panhard and Levassor car which was run in the Paris-Marseilles-Paris Race of 1896. In both cases the number of cylinders is the same. But if I have no right to take up a challenge issued in connection with the 6-cylinder car because the Rolls-Royce was not the first car built with 6 cylinders, then Captain Deasy should have no right to appear as the champion of the 4-cylinder cars with a Martini car, since the Panhard, and not the Martini, was the first car built with four cylinders. And, after all, I think it will be granted that Mr. Edge is quite capable of defending his rights, without the assistance of the gentleman in Birmingham.

Yours faithfully,
C. JOHNSON.

February 27th.

Enclosed Extract from Report of Speech by Mr. Claude Johnson at a dinner given by Mr. Edge, Feb. 24th, 1906.

"Quite recently, within the last few days, he saw in a paper a mistake which he thought ought to be rectified. It was said that a 6-cylinder car had been shown at the Paris Exhibition of 1902, of a make which was not Mr. Napier's make. Now, he thought that was a slight error. He asked his friend, Mr. Spooner, of THE AUTOMOTOR JOURNAL, to make a search, and Mr. Spooner had kindly stated that so far as he could ascertain the 6-cylinder Napier car was first described in October, 1903, there being a car running at that time, while the foreign 6-cylinder car which was mentioned in the column referred to, and which was said to have been exhibited at the Paris Exhibition of 1902, was not—so far as he could ascertain—shown until the Paris Exhibition of December, 1903. This was quite a different matter; but apart from Mr. Edge having made the first 6-cylinder car, Mr. Johnson did not think that anyone would deny that it was Mr. Edge who first put a 6-cylinder car on the market as a commercial article. That honour must rest with Mr. Edge and Mr. Napier."

* * *

RACES, RECORDS, AND TRIALS.

Circuit Européen.

"THE de'il tak' the hindermost" will probably be the motto of the 5,000 kiloms. rush through Europe in July and August next, to be known as the Circuit Européen. That it will resolve itself into a mere scrambling race, with its consequent serious drawbacks, there can be little doubt, owing to the decision by the foreign club delegates in Paris to suppress the official observers on the cars, relying for the chief point in the classification upon the times taken at starting and arrival. Breakdowns, from whatever cause, will be taken no notice of, so long as competitors arrive daily at their mid-day and finishing points within the specified official times. What this will mean can only be estimated by those who have taken part in some of the Continental "go-as-you-please" jaunts—not forgetting the historical Paris-Madrid calamity. On arriving at the awards, the makers of the cars will receive the medals, not the drivers.

The commencing date has been altered to July 26th, and the finish on August 15th, making 21 days, 6 of which will be devoted to exhibitions, and 15 to racing. The daily itinerary otherwise remains practically the same as given in THE AUTOMOTOR JOURNAL of February 3rd.

Weighing-in of cars is to extend over 3 days, viz., July 23rd, 24th, and 25th.

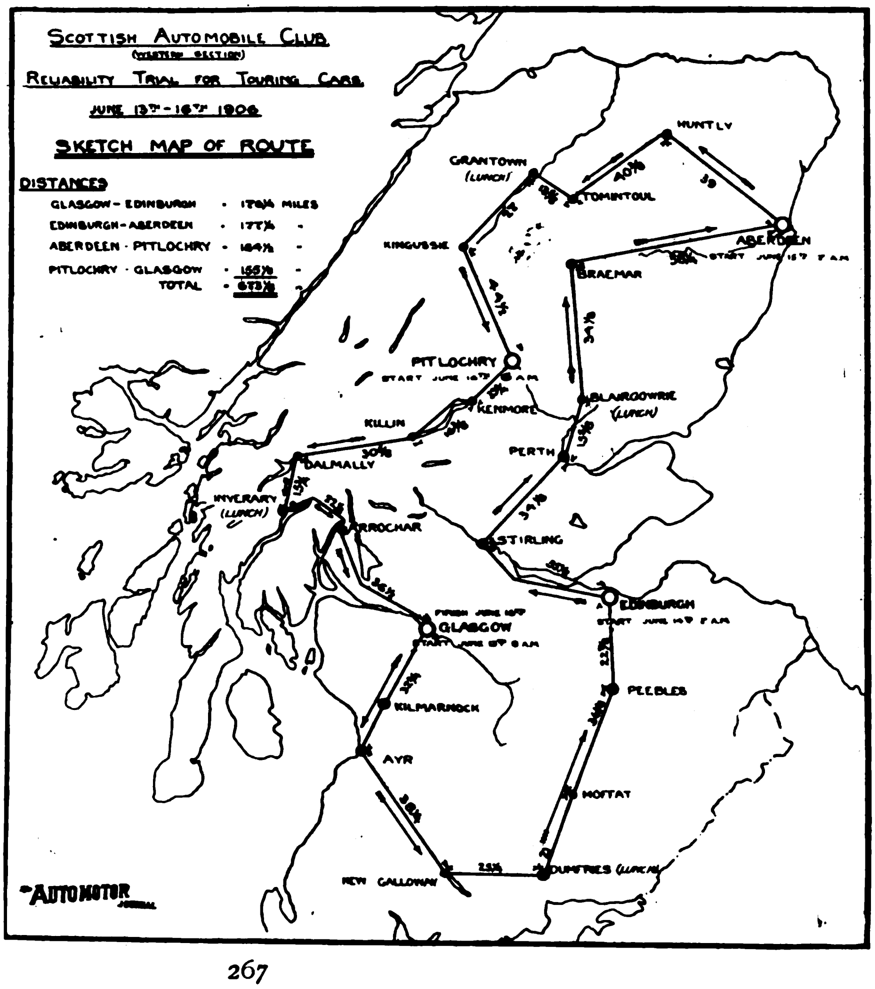
A category for steam cars, based upon the heating surface of the boiler, is to be created.

Paris-Nice Record.

A REMARKABLE journey is reported to have been made last Saturday by Baron de Caters. Starting at 7 a.m. from Paris, on a 120-h.p. Mercedes "Tourist" car, he arrived at 10.45 p.m. at Nice the same day.

Scottish Reliability Trial.

THE Scottish Automobile Club (Western Section) have now issued the rules for this year's Scottish Reliability Trial for touring cars, which is being held from June 13th to 16th next.



On this occasion, the route, which is well shown in our specially prepared sketch-map, will be as follows :—

First day : Glasgow, Ayr (*viâ* Kilmarnock), New Galloway; Dumfries, Moffat, Peebles (*viâ* St. Mary's Loch), and Edinburgh, 176¼ miles.

Second day : Edinburgh, Stirling, Perth, Blairgowrie, Braemar (*viâ* Spittal of Glenshee), and Aberdeen ; 177¼ miles.

Third day : Aberdeen, Huntly, Tomintoul, Grantown (*viâ* Bridge of Brown), Kingussie, and Pitlochry ; 164½ miles.

Fourth day : Pitlochry, Kenmore (*viâ* Struan and Tummel Bridge), Killin, Dalmally, Inveraray, Arrochar (*viâ* Glen Croe), and Glasgow (*viâ* Loch Lomond) ; 155⅛ miles.

making a total distance of 673⅛ miles.

The main alterations in the rules are (*a*) the classification, which will be by price ; (*b*) a non-stop performance is not now essential to eligibility for a medal award. This decision has been arrived at after very careful deliberation, in view of the fact that it has been considered that a hardship was apparent as regards several cars which last year lost their non-stop certificates through "driving stops" or other minor causes. Stops for tyre troubles have been altered, and the system of making the awards is on an entirely new basis. The following are the main points of the rules :—

Entries.—In each class only one car of any specific make, type and h.p. will be accepted, and no cars will be considered of different horse-power unless the cylinder capacities vary by at least 15°/ₒ. In accepting entries, preference will be given to those by (1) a maker, or (2) the nominee of a maker.

The classes will be as follows :—

	Petrol vehicles.	Entrance fee.
A.	Selling price of chassis up to £200	12 guineas.
B.	,, ,, £200 to £350 ...	12 ,,
C.	,, ,, £350 to £500 ...	15 ,,
D.	,, ,, £500 to £650 ...	15 ,,
E.	,, ,, over £650	15 ,,

F. Steam cars.—The fees of Class F are the same as for the respective petrol classes, according to price.

The Committee may sub-divide any class, combine any classes, or create any new class if deemed desirable. Petrol cars showing more than 12 h.p. on the following formula must have a seating capacity of at least four :—

$$\frac{\text{Cylinder diameter in inches}^2 \times \text{number of cylinders.}}{3}$$

Objects.—The trial is one essentially of reliability, with the object of demonstrating the suitability of modern motor vehicles for touring purposes. It will form, for all practical purposes, a "non-stop run." Maximum and minimum times will, as usual, be fixed for each respective class of vehicle for covering each road section of the trial, having due regard to the nature of the roads and towns and villages to be traversed, and to the reasonable requirements of the buying public in the matter of speed of cars. An official observer will travel on each vehicle.

System of Marking for Reliability.—A maximum number of marks will be allowed for the run, and as usual 1 mark will be deducted per minute during which the vehicle is at rest, except for tyre troubles, compulsory and traffic stops, and stops authorised under the rules for accidental detours, lighting lamps, &c. In addition, 1 mark will be deducted for every minute in excess of the maximum time allowed for any stage, and 1 mark per minute for finishing any stage in advance of the minimum time. Up to a maximum of 1 hour, in the aggregate, will be allowed during the trial for stops for tyre repairs or troubles ; excess time beyond this will be reckoned as involuntary stops, and 1 mark for each 5 minutes or part thereof, in excess of stops over 1 hour, will be deducted and will count against the car in its marking for reliability or medal awards, no vehicle with such stops exceeding 1 hour in all being eligible for a non-stop certificate. During such tyre trouble stops, no other adjustment or repair must be carried out, and engines must be kept running except under certain conditions.

Hill Climbs.—Times will be recorded on several hills, and the performances taken into consideration in the determination of the medal awards.

General Conditions.—Each vehicle must carry its full complement of passengers or equivalent weight (11 st. per passenger) throughout, in addition to tools, luggage, fuel, oil, &c., but no passenger will be allowed to ride beyond the fixed seating capacity of each vehicle. Only recognised touring bodies may be fitted. Fuel and water tanks must be of the ordinary recognised size and capacity, as usually sold to the public, no extra fuel or water beyond that contained in the usual tanks, except the remainder of a tin of petrol partially used, may be carried. Arrangements for supplies of petrol, oil, &c., *en route* must be made by each entrant. The fuel consumption will be measured and stated in the certificates.

Entrants will be bound to sell for delivery within a reasonable time, similar motor cars and chassis to those entered, at the price stated, for three months after the date of the trial.

The chassis length has to be declared, and the chassis price is the base of classification, this price including tyres, and only tyres of the nature, make, and dimensions stated in the entry form may be used in the trial. Remarks as to the behaviour of the car during the trial, or as to parts which at the end of the trial show, in the opinion of the club, an undue amount of wear, may be added by the committee to the certificate.

Fifty minutes will be allowed daily for luncheon stops, of which 13 minutes will be allowed for replenishing fuel and lubricants. Twenty minutes for a like purpose will be allowed before re-starting from Edinburgh, Aberdeen and Pitlochrie. Any parts replaced must be notified in writing to the club. Sprockets must not be changed during the trial, and the driver or mechanic must not leave their seats to make any adjustment or repair while the car is running. Brakes may be tested at any time by the committee, and if in their opinion danger is involved to the occupants or the public, they may refuse to allow the car to continue in the trial. Five minutes per day will be allowed, without penalty, for the adjustment of brakes. Cars will re-start each day after luncheon in the order of their arrival ; the order of each morning's starting will be determined by the committee. On all occasions 2 minutes will be allowed to start the engine. The same driver must have charge and drive during the entire trial, except by consent of an official of the club. Any vehicle which may be pushed or assisted during the trial, including the hill climbs, or does not carry its full complement of passengers, will not be eligible for a non-stop certificate award.

Awards.—The club will award an efficiency gold medal in each class. The award of this medal in each class will be made to the car making the best performance on the following basis.

800 marks will be the maximum for reliability, subject to deductions for involuntary stops, for time in excess of maximum or short of minimum running time, for tyre stops in excess of one hour, for starting and stopping on hill tests.

100 marks will be allotted to the vehicle in each class making the best time in each hill-climbing test adopted, and the others will be allotted a percentage equivalent to their respective performances, and the average of the marks so gained will be taken, 100 being consequently the maximum possible.

100 marks will be allotted to the vehicle in each class showing the lowest fuel consumption per ton-mile over the whole trial, and the others will be allotted a percentage equivalent to their respective consumption per ton-mile.

The medal will be awarded to the vehicle in each class obtaining the highest aggregate marks.

The above is expressed in the following formula :—

$$\text{Marks gained for reliability} + \frac{\text{Total marks gained in hill climbing tests.}}{\text{Number of hill-climbing tests.}} + \frac{\text{Lowest petrol consumption per ton-mile in class} \times 100}{\text{Fuel consumption per ton-mile.}}$$

A special award or awards to any vehicle or vehicles competing in the Trial may be awarded by the club in their own discretion if its performance or other consideration warrants it. In addition a silver cup, to be called the "Scottish Cup," will be awarded to the vehicle (excluding steam cars) which shows the lowest fuel consumption per ton-mile over the whole trial.

Starts will be made each morning between 6 and 8 a.m. A vehicle not in place to start within 30 mins. of the specified time will be disqualified. Stopping and starting tests may be enforced by the committee on any hill or other part of the route, and marks deducted in the event of failure to restart within 30 secs.

Applications for forms and entries should be made to the Hon. Secretary, Mr. Robert J. Smith, C.A., 59, St. Vincent Street, Glasgow, not later than May 2nd, after which entries will be formally accepted. For 21 days thereafter double entrance fees may possibly be charged.

The Tyre, Speedometer and Lamp Trials.

FOLLOWING the preliminary weighing, marking and testing of the tyres, vehicles and instruments, the Dennis, Daimler and Rolls-Royce touring cars, with their Collier tyres, started off for the initial run on Thursday morning. The Crossley-Leyland 'bus, with "Hartridge" solid tyres, joins the trial later.

Clifford Earp's Remarkable 100 Miles Napier Record.

OUR readers will call to mind the account which we gave at the time of Mr. Clifford Earp's wonderful performances with a 6-cylinder Napier car on the Ormond-Daytona Beach, and how he overcame tyre and wheel troubles (we say both advisedly) which might well have knocked an average driver out of time and lost the race. Mr. Earp reached Liverpool by the "Baltic" last Friday night, and was good enough to give us a look in, immediately upon his arrival in London, as we were naturally enough anxious to hear the ins and outs of the story. Mr. Earp confirms definitely the accuracy of the principal times we were able to give at the date of the race. He particularly mentions the extraordinary performance of covering 9 miles in exactly 5 minutes, or maintaining a speed for that period, of exactly 108 miles an hour.

But it was about the lost tyre, and the broken wheel, and the fact that in spite of the lost tyre and the damaged wheel—six spokes broken on one side and eight on the other—with which he was able to finish and win the race, that we were naturally most athirst for information. When 34 miles of the distance had been covered, the Palmer tyre on the right rear wheel, which had not been tested for pressure before the race, and had been left without any special attention or examination for some days past, gradually went down for no apparent cause, all the tyres otherwise being in perfect condition. The car had to be drawn out of the course in accordance with the Florida Beach rules, and it proved no easy job to get the offending tyre off. They are not the sort of tyre to drop off when merely deflated, convenient as that might be under certain circumstances. At length the task was accomplished, however, and Earp, with 14 minutes lost through his stop, attempted to re-start his car in spite of the tremendous lurch that it suffered from the 4-inch tyre being removed from the right rear wheel, the rims bedding into the sand and bringing that side of the vehicle a good six inches lower than the other. However, the engine was started up and the power successfully transmitted to both the driving wheels, but, alas, the tyreless one span round in the sand. Then Earp started as slowly as possible, and in conjunction with Bater, his mechanician, shoved behind, and when the car began to move then the sand splutter ceased, it gradually gripped, and Earp, having regained his seat a few moments after, Bater was able to jump on at the back just in time not to be left behind. From that moment no further check was experienced. The car not only gripped and ran as well without a tyre on its rear wheel as did the other competitors, but gradually gained and gained and gained on the other competing cars till it won the race.

Vanderbilt Cup Race.

THE French Club having declined to run this race in France this year, arrangements are to be made for the contest to again take place in America. No locality has yet been settled, although there are, it is reported, several where the selection would be welcomed. The organisers will take time to think it over, and in the meantime it is understood, semi-officially, through Mr. Morrel, of the A.A.A., that "any place in the country that has aspirations in this direction may make its attractions known." Nassau County, Long Island, authorities are desirous that the race should again take place in their district.

Nice Week.

TOURIST cars over 1,000 kilogs. in weight are to be allowed to take part in the speed trials over the mile and kilometre.

Voiturettes and Tri-Car Trial.

ORGANISED in Paris by *Les Sports*, a contest for these small vehicles was concluded on Sunday last. In all, three voiturettes and six tri-cars "weighed in," three only of the latter finishing. The first place in the voiturettes class was secured by a Gregoire car, the tri-car section prize falling to a Griffon machine. The trial consisted of six daily journeys, starting each day from Paris, making a total of 1,200 kiloms. The results are given in the table below :—

Class I.—Tri-cars.

Cylinders, 500 *cmc.* *Minimum weight passengers*, 140 *kilogs.*

	Machine.	Driver.	Bore and Stroke.	Cylinders.	Marks Lost.
			mm.		
1	Griffon ...	Bucquet ...	82 × 90	475·20	787
2	Bruneau ...	Foulon ...	74 × 76	326·85	1298
3	Austral II. ...	Guitard ...	80 × 90	452·34	1414

Class II.—Voiturettes.

Cylinders, 700 *to* 1,250 *cmc.*

1	Gregoire I. ...	C. de Bosch ...	80 × 110	1105·80	233
2	Vulpes ...	Barriaux ...	100 × 120	942·46	457
3	Gregoire II. ...	Cornil ...	80 × 110	1105·80	1576

* * *

AERONAUTICS.

A Prize for Model Flying Machines.

As long ago as October last, Major Baden-Powell offered a prize for flying machine models of the heavier-than-air type. The value of the prize was to be £10, and the competition for it was to take place at the summer meeting in July of the Aeronautical Society of Great Britain at Sunningdale. The main conditions governing the competition are as follow :—

1. The apparatus may be of any form, but shall not weigh, all complete, more than one pound.
2. No gas or hot air for buoyancy shall be used.
3. Any propelling force such as compressed air, petrol, spirits, &c., may be employed (although it is probable that indiarubber springs will alone be found practicable in so small a machine), but no springs, explosives, or other agencies apart from those carried by the machine and included in its weight shall be used to give an initial impulse.
4. The apparatus shall be started from the ground or from a table or releasing gear not more than six feet above the ground.
5. The apparatus shall fly through the air for a distance of at least 100 feet, so that the distance from the ground from place of starting to place of falling shall be when measured in a straight line, not less than 100 feet. It must accomplish this distance twice over (with a short interval between) in opposite directions.
6. The prize will be given to the competitor whose machine covers the greatest distance.
7. The prize will not be awarded unless there are three or more genuine competitors.
8. Each competitor shall be held responsible for any damage or accident that may occur to or by means of his apparatus.
9. The competition shall be open to all of any nationality, who shall be approved by the Council of the Aeronautical Society of Great Britain.
10. Members of the Aeronautical Society of Great Britain shall have to pay no entrance fee, but to non-members there shall be an entrance fee of five shillings for those who are entered before the end of 1905, and half a guinea for those who are entered between January 1st and April 30th, 1906, the latter being the last day for receiving entries.

11. The award of the prize shall be decided by a jury of at least three members, to be appointed by the Council of the Aeronautical Society of Great Britain, who shall decide all points of doubt, and use their discretion as to the disqualification of any apparatus which they may consider not to comply with the original purpose of the competition, or one which they consider in any way dangerous.

12. The decisions of the jury shall be accepted as final.

The Barlatier–Blanc Aeroplane.

A NEW aeroplane of the superposed wing type has been built by M. Paul Barlatier, of the Automobile Club of Marseilles, and M. Blanc, of the Automobile Federation of the South West. The Barlatier-Blanc airship is well stayed together, but its planes are rather excessively curved or bent, and so far it has not, as we gather, been successfully navigated.

Cross-Channel Ballooning.

WE descanted last week on the splendid effects on the health produced by even ordinary ballooning voyages, and an example of this contention is provided by the recent experiences of Mr. Frank Butler, Mrs. Griffith Brewar, and Mr. Percival Spencer, who set forth from the Putney Gas Works at 2.15 p.m., and after a magnificent passage alighted at Haversant, some twenty miles south of Boulogne. While in full career above the Channel, the intrepid aeronauts consumed an indigestible meal of champagne, cake and sausage roll, a clear proof that the sport of ballooning brings the internal organs into a state of fine temper that absolutely nothing can upset.

Some Incidents of the Flight.

NOT long after leaving the English coast, the aeronauts heard an unusual buzzing noise coming up from far beneath, apparently from the Channel, which seemed to their enlarged vision little wider than a canal, so clear was the atmosphere and so high up were they. They could see nothing, however, owing to a passing cloud, till at length they observed one of the new turbine steamers, which was ploughing along at a great pace, and had a decided start of the balloon. The wind, however, was blowing fairly strongly, and in spite of the handicap the balloon beat the turbine steamer easily, and arrived at the French coast well before it. Indeed, the performance is a remarkable one for a balloon journey, as the travellers were back in London some fifteen hours after leaving the gas works.

A Correction.

ALL aeronauts will be glad to learn that M. E. Archdeacon, to whose sudden and unexpected death we referred last week, was not, as a matter of fact, the celebrated experimenter and encourager of aeronautic research who has been so generous a patron of the art.

* *

Steam Cars in Competition with Petrol Cars.

IT must be distinctly encouraging to the advocates of steam pleasure vehicles that a steam car should have succeeded, on the score of fuel consumption, in winning the touring-car prize in an endurance trial in America recently. The result of this event—the Los Angeles-San Diego run, in which a White steam car obtained the first prize in the heavy class—was recorded in THE AUTOMOTOR JOURNAL of February 17th, but we now have further particulars concerning this remarkably successful performace. During the two days' run, over a distance of 180 miles, there were four controls each day, stoppages being made mid-morning, noon, mid-afternoon, and at night, while the main system of marking was to deduct one mark for every minute of delay on the road, or of work in the garage, from the 1,000 marks with which each car was credited at the start. To avoid any possibility of two cars tieing for the first place, it was further arranged that in such an event the amount of fuel used should first be considered, that failing this the quantity of lubricating oil used should be taken into account, and that if by any chance the performances were still equal, the car keeping nearest to schedule time should be the winner. In the result the White steam car, driven by Mr. C. A. Hawkins, and also a 4-cylinder Packard car (petrol) succeeded in completing the run without the loss of a single mark. The White steam car, however, only used 17 gallons (American) of fuel, as against 21 gallons consumed by the Packard, and consequently secured the prize, as well as the special J. B. Spreckle Cup offered for lowest fuel consumption. In view of the mountainous nature of the country, and the roughness of the roads, it was a remarkable performance, and cannot but raise the hopes of all those who hope to see steam cars successfully holding their own with petrol cars, even in races based upon the lines of the Tourist Trophy—a type of competition in which it is by no means derogatory to the good all-round capabilities of steam cars that they cannot at present compete on equal terms with petrol vehicles.

Mr. Harvey du Cros, M.P., J.P.

A VERY pleasant surprise was sprung upon Mr. Harvey du Cros at Regent Street, last week, when he was unexpectedly invited to receive an address from his staff and the employees of his various motor businesses upon the occasion of his return to Parliament. Mr. du Cros, who was accompanied by Mrs. du Cros, was particularly gratified at this spontaneous show of appreciation by those associated with him. Among those who spoke on behalf of their respective departments, congratulating Mr. du Cros on the splendid victory which he achieved at Hastings, were Mr. Reginald Chanter, representing the Panhard and Levassor staff and employees; Mr. W. A. Turpin, manager of the works at Kimberley Road, Kilburn; Mr. E. H. Lancaster, for the Clement Company; and Mr. A. McCormack, for the Gladiator Company. The formal address was presented by Mr. Reginald Chanter.

Mr. Harvey du Cros, M.P., in responding, was evidently very deeply touched, and he said that although he had been speaking a good deal for the last two years, it was to very different gatherings than to that at which he was then present. This one was more intimate and personal. He was extremely glad he had won at Hastings, but he was prepared to confess that when he began that fight he had no idea it was the sort of thing it turned out to be, and when it was over he was so tired that he did not know whether he was glad or sorry. Since then he had been away and had had a little rest. The meeting which he was now attending had turned the scale, and he now knew that he was glad, and he was not in the slightest doubt as to his feelings with regard to his election at Hastings under the circumstances. He thanked them very heartily for the remarkable assistance which they one and all had given to him in his fight, and he concluded by saying that nothing could have pleased him more than to have received an address in the form in which it was presented, where all of the names of those associated with him were entered. It was a thing he would be very proud of, for all time, the more so as the whole affair was entirely unexpected.

The Menu Card at Mr. S. F. Edge's Dinner last Saturday. The design represents the development of the motor trade. In the top left-hand corner, Mr. Gordon-Bennett is seen writing his offer of the now famous Gordon-Bennett Cup to the French Club, this act being supposed to have started the popularity of motoring, which was fostered and developed by the Press, as depicted in the right centre picture, resulting in the construction of huge factories, shown in the bottom right picture, all of which however, as Mr. Edge pointed out, were dependent upon the signer of cheques hinted at in the bottom left corner.

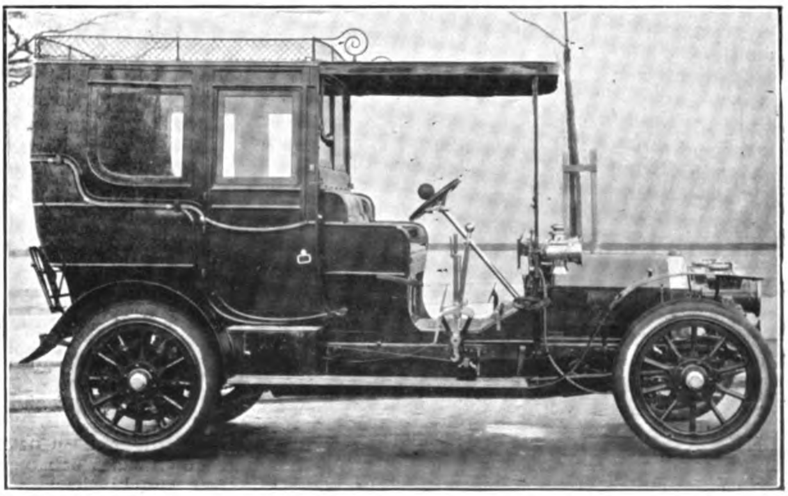
Mr. S. F. Edge gives 3 years' Guarantee.

In years to come, February 24th, 1906, will be memorable in the automobile world as the date upon which a British firm led the world in giving a three years' guarantee with each motor car purchased. The firm is Messrs. S. F. Edge, Limited, and the car, the Napier. This announcement was the main object of a very enjoyable little dinner to which Mr. S. F. Edge invited his many friends of the Press and others on the date above mentioned. To look back but a comparatively short number of years, and remember the almost hourly mishaps that occurred to the majority of cars, it almost seems impossible that such progress could have been made as to justify such an important and bold departure. Some French manufacturers, who heard of Mr. Edge's new scheme, point blank declared to him that to their minds it would mean bankruptcy, and that French firms would surely not follow the lead. Mr. Edge, nothing discouraged, has replied by his public announcement. It remains to be seen how far competing firms can afford to remain outside giving a similar undertaking. Another historical point made at Mr. Edge's gathering was his calculation that for the first time the value of British motor cars manufactured during January, 1906, amounting to £468,000, exceeded the foreign imports of £317,000 for the same month—a result of which the British industry have good reason to be proud. Moreover, Mr. Edge estimated that the total value of cars which 1906 would see manufactured in Great Britain would probably reach £6,000,000 sterling.

One note of regret was apparent at the dinner—the absence of Mr. Napier, the man who has built the now world-famous car known under his name—and the regret was the keener through illness, requiring a lengthened change of scene, being the cause. Even Mr. Napier would, however, have felt satisfied with the reception, in his absence, of the toast of his health, following a *résumé*, by the host of the evening, of the remarkable part which Mr. Napier had played in the development of the motor industry, both on land and sea, from 1899 up to the present year, 1906, resulting in a change from a dozen men making *a* Napier car in the former year to a wage list alone of £300 per day at the present time. That Napier cars are now being made in America and Italy we already knew, and on the same evening we learned that Russia had come forward and proposed establishing a factory to construct cars to Napier designs.

Mr. Edge, in urging British makers to press forward in establishing Great Britain as the head of the world's motor industry, said that racing on land and sea was an essential to further developments—twelve hours' racing experience, he believed, taught more than three months' ordinary running. The introduction of the 6-cylinder principle, he maintained, would lead to the reduction of the expenses of motoring, and he was glad to note that this was so much appreciated that there were already thirty-five makers copying this principle, the latest being the Mercedes.

Besides "The King" the only formal toast was that of "The Host," very aptly proposed by Mr. Claude Johnson, who was able to fill in many blanks in the history of the development of the British motor industry which Mr. Edge in his modesty had omitted to credit himself with—including the introduction commercially of the 6-cylinder car.



One of the new 1906 model 20–25-h.p. Brotherhood cars. This identical carriage has been acquired by the Rt. Hon. Earl of Mar and Kellie.

"Pioneer" Motor 'Bus Service.

THE London Power Omnibus Company opened last week their new garage at Cricklewood. It is 250 ft. by 80 ft., and is stated to be the largest in the world, accommodation for 150 double-decked omnibuses being provided. The buildings and yards are lit by electricity throughout. In addition to two spacious yards there is a large repairing shop, and ample office accommodation. The whole establishment covers about 1½ acres. The method of the storage of petrol is underground in two huge tanks, each with a capacity of 3,000 gallons. The petrol is then pumped into a cistern above ground, from which it is conveyed, to the 'buses through pipes, also underground, to "traps" (as shown in our photograph). There are 12 of these "traps," so that 12 'buses can be charged at one time. A novel feature on these "Pioneer" 'buses is the broad projecting front rubber "buffer," which is intended to break the force of a collision, and protect the radiator. We reproduce this week some interesting photographs of the "Pioneer" establishment.

THE "PIONEER" MOTOR OMNIBUS GARAGE.—**General view of the large building in which standing room is provided for 150 double-decked omnibuses.**

Honouring Automobilism.

M. L. MORS has received the Cross of the Legion of Honour.

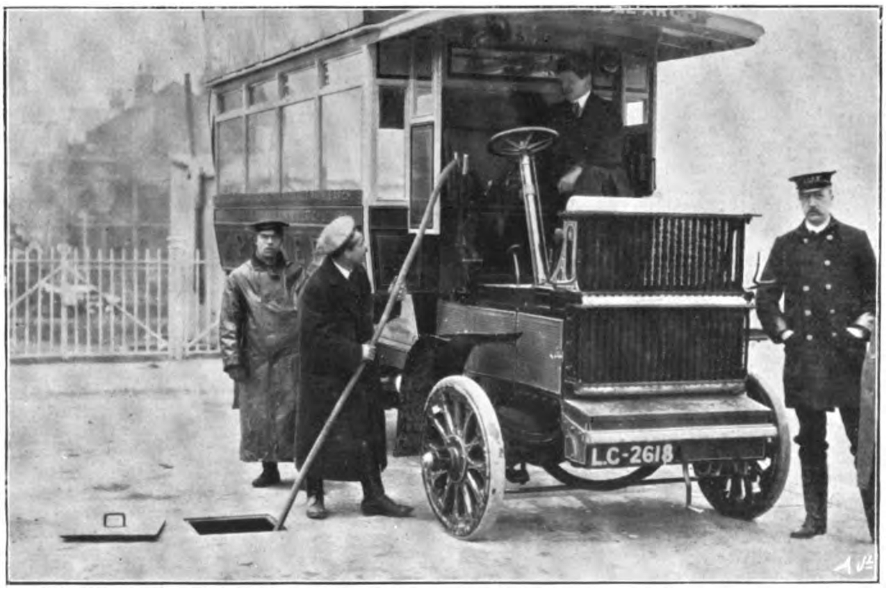
A Warning Example.

ONE of the persistent bicyclists who make a practice of riding behind motor cars as close as they can, and sometimes even running into them, has had a salutary lesson. This particular sample of recklessness was riding behind Lady Warwick's motor car when it was being driven home by her chauffeur. He collided with the car, probably owing to an unexpected slackening of speed, and injured his machine, after which he had the impertinence to bring an action for damage against both Lady Warwick and her chauffeur jointly. Needless to say he was not awarded a penny.

"An Elastic System of Control."

AT the last meeting of the Surrey County Council Mr. H. H. Gordon Clarke moved the adoption of a resolution:—

> "That this Council is of opinion that the next Act to regulate motor traffic should confer such powers on one of the State Departments as would provide an elastic system of control without the necessity of frequent recourse to Parliament."



THE "PIONEER" MOTOR OMNIBUS GARAGE.—**Filling up a petrol tank on an omnibus. By similar means the tanks of twelve omnibuses can be filled at the same time from various "traps," drawing off their supply through a high-level cistern in connection with the main supply contained in two huge underground tanks.**

Encouraging "Home Industries."

THE Emperor of Germany has now three 70-h.p. Mercedes cars. His latest acquisition is a 1906 model of 45 h.p.

A Big Blaze.

A FIRE at motor car and repair shops at Moncton, near Ottawa, is reported, whereby damage amounting to £300,000 has been done. A valuable car belonging to Earl Grey was amongst the property destroyed.

Fee for Climbing the "Radical Road"—3 Guineas.

As a sequel to the feat of climbing the Salisbury Craggs in Edinburgh, by way of the "Radical Road," Mr. Charles Jarrott was mulcted in three guineas at the Edinburgh Burgh Police Court last week, the official seal being thus set upon this performance.

Original Humorous Sketches by Tom Browne, R.I., at the Dinner of the Blackheath Automobile Club.

Blackheath A.C.

THE annual general meeting and dinner was held at the Art Club, Blackheath, on Friday of last week, Col. Holden, R.A., in the chair, when fifty members and guests were present. Amongst the routine business of the annual general meeting the annual report and balance sheet was accepted and passed, and the following officers elected :—

President: Lord Hugh Cecil.

Vice-Presidents: Col. H. C. L. Holden, R.A., F.R.S. ; Prof. Carlton J. Lambert, M.A. ; Hon. Arthur Stanley, M.P.

Committee: Messrs. H. Cunis, J. Strickland Goodall, M.B., Arthur Jackson, E. W. Stabb-Johnson, Ralph Lucas, T. Marshall, J. T. Prestige, jun., Fred Thorne.

Hon. Treasurer: Mr. H. J. Fisher. *Captain:* Mr. Leonard Beadle. *Hon. Sec.* : Mr. Alfred Roberts.

Following the business a musical programme was much enjoyed. Dr. Goodall, the poet laureate of the club, recited some verses he had ably composed, describing the various peculiarities of the officers of the club, which proved most amusing.

The *bon bouche* of the evening was the lightning sketches which Mr. Tom Browne, R.I. (member of the club), kindly made, and which, by permission, we reproduce, depicting the features of "the man who does not like motor cars," "keep on his right side" (head of a constable), and "the motor face," which were extremely clever character studies, and their rapid delineation causing great interest to the onlookers.

Ladies' A.C.

AT the invitation of the Countess of Amherst, members of the L.A.C. will meet at Montreal, Sevenoaks, on March 17th.

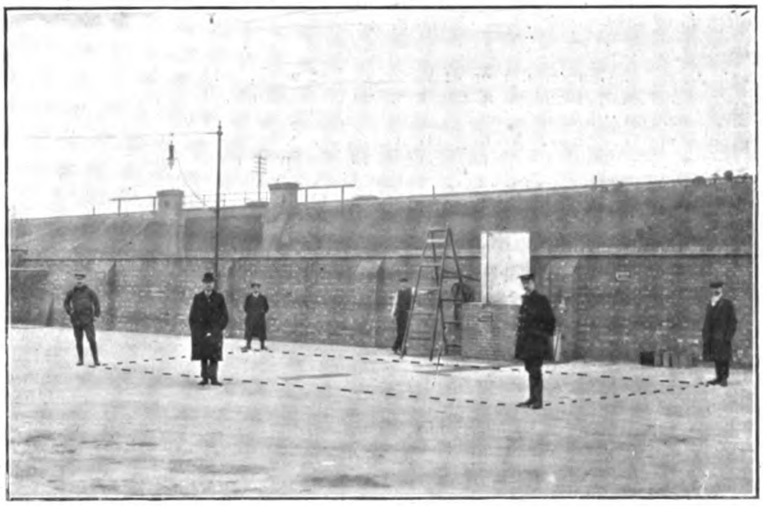
Mrs. Edward Manville must have felt particularly gratified at the huge gathering of members and friends at the club last week, upon the occasion of her reading a paper, "A Try for the Herkomer Trophy," which is reproduced elsewhere in THE AUTOMOTOR JOURNAL this week. It proved of great interest, and Professor Herkomer, who was present, personally complimented Mrs. Manville upon the very interesting *résumé* of her experiences. Lady Cecil Montagu presided, and amongst those present were Princess de Polignac, Lady Edward Spencer Churchill, Lady Margaret Jenkins, Lady Geraldine St. Lawrence, Lady Maud Parry, Lady Beatrice Rawson, the Countess of Kinnoull, Baron and Baroness Campbell Von Laurentz, Mrs. Von Herkomer, and Miss K. d'Esterre-Hughes.

Motor Union.

THE general committee of the Motor Union, at its February monthly meeting, added the following distinguished members to its list of vice-presidents :—His Grace the Duke of Beaufort, J.P., D.L., the Right Hon. Earl Cairns, the Right Hon. Lord Wenlock, K.C.B., the Right Hon. Lord Llangattock, J.P., D.L., Sir Charles Seely, Bart., J.P., Sir George Livesey, M.I.C.E., and Mr. N. Micklem, K.C., M.P.

Considerable additions to the membership of the Union were reported, bringing the total number of clubs included in the Union up to 64, and its aggregate membership to upwards of 10,800.

The annual meeting of the Motor Union will be held on Wednesday, March 28th, at the Agricultural Hall. It has also been arranged that members of the Union shall be admitted free of charge to the Motor Car Exhibition (which will then be in progress) on the above date, and also on the opening day of the Exhibition, namely, Saturday, March 24th.



THE "PIONEER" MOTOR OMNIBUS GARAGE.—The storage of petrol for use by the omnibuses is in two enormous underground tanks at the Cricklewood Garage. The size of the tanks may be judged from our photograph, the dotted lines, with a man at each corner, showing the square space occupied by one of them. In the background of the photograph will be noticed the special high-level cistern to which a force-pump is attached, from which the supply to the several "traps" is conveyed for filling up the tanks of the omnibuses as required, for daily service.

The Hon. H. L. Bruce, accompanied by Mr. Colin Defries, in his 40-h.p. De Dietrich car. Mr. Bruce has been driving a considerable distance through England, having in the last twelve days covered about 1,400 miles, our photograph being taken by Mr. Hazel, of Bournemouth, during Mr. Bruce's recent journeyings.

CLUBS AND ASSOCIATIONS—*continued.*

British Motor Boat Club.

The club, we are informed, is now appointing at various ports on the coast, and in various districts on the Thames and other rivers and estuaries, official repairers and water garages. In doing this, the aim is to endeavour to get a uniform and reduced scale of charges for members of the club. The same system is also being carried out with regard to hotels at the various seaports and on the Thames.

The opening meeting of the club will be held on May 5th on the Thames.

At the Agricultural Hall Motor Show, a reception of the club will be held on Friday, March 30th, in the Reception Hall placed at the disposal of the club by Messrs. Cordingley.

Burnley A.C.

AFTER the annual dinner of the club last week, held at the Empress Hotel, Burnley, a paper was given by Mr. Douglas Mackenzie on "Transmission in Motor Cars," illustrated by photographs and diagrams. During the course of the evening the secretary, Mr. Smith Lawson, announced the receipt of a communication from the North-East Lancs. Automobile Club, suggesting the advisibility of an amalgamation of the two clubs. It was, after some little discussion, decided to call a general meeting of the members to decide the question.

Society of Motor Manufacturers and Traders, Ltd.

THE increasing membership and the extension of the interests of the Society of Motor Manufacturers and Traders have from time to time caused the formation of separate sections, such as the commercial vehicle, the marine motor, and the tyre and accessories sections. It has been decided to add yet a fourth, for carriage builders. Amongst the members of the society there are many of of the best known carriage builders, whose interests in connection with the motor trade have now become very considerable, and who are represented at the Society's Exhibitions at Olympia by samples of carriage work generally of the very highest character.

The Automobile and Cycle Engineers' Institute.

THE adjourned meeting of the London Section for the discussion on Colonel Crompton's paper, "Some Unsolved Problems in Motor Engineering," will take place on Wednesday next, the 7th of March, at the Royal United Service Institution, Whitehall, London, at 7.30 p.m. prompt.

All those who intend to take part in the discussion are requested to lodge their names with the secretary at least three days before.

COMPANY DOINGS.

A. Darracq and Co. (1905) Limited.

AT the statutory meeting of the company, held last week, at which Mr. J. Sydney Smith-Winby, the chairman of the company, presided, the prospects of the company were dealt with by the chairman, and appeared to be of the most promising character. Since October 1st, when the new company took over the business, the progress had been thoroughly well maintained, and a great rush of business had been going on the whole time. In dealing with the question of heavy traction, Mr. Smith-Winby mentioned that apparently every day almost saw the birth of a new motor omnibus company. They had been very much pressed to undertake the manufacture of these vehicles, but had been compelled to decline the offer of orders that had been made them, for the reason that Mr. Darracq, who had carefully studied the whole subject for some time, was very distinctly of the opinion that a really practical and efficient type of motor omnibus had yet to be evolved. Mr. Darracq was still engaged upon this question very carefully, and later on he hoped to have an interesting announcement to make upon the subject. The chairman also mentioned the establishment of a branch factory in Italy in the neighbourhood of Naples, which would be an Italian company of very considerable importance and value to their company. This factory, they hoped, would be in full operation within six or seven months.

A very cordial vote of thanks to the chairman and directors was passed for the admirable way in which the business of the company had been conducted, and the proceedings terminated with a general feeling of satisfaction amongst the shareholders.

London and South Coast Motor Service, Ltd.

SOME interesting particulars were given at the statutory meeting of this Company held last week, when Mr. Carlton Roberts, Chairman of the Company, presided. Mr. Roberts stated that the business which they had acquired of Mr. J. W. Cann, of Folkestone, was taken over by them on December 15th last. The receipts since then had worked out at a fraction over 5*d.*, and the running expenses at a fraction over 2¾*d.* per mile run, these figures representing the receipts at their lowest for December, January, and February. During the summer season their cars, he stated, running with a full complement of passengers, earned on an average 1*s.* 2½*d.* per mile, while the expenses did not exeeed 4½*d.* He then drew attention to certain patents of the Company's, one of which had passed, he said, the experimental stage, having enabled them to run 8,600 miles with tyres which were ordinarily expected, though not guaranteed, to run 4,000 miles, bringing the ascertained actual cost of their tyres to ¾*d.* per mile run, in comparison with what he understood the estimate for the cost of tyres, supplied to motor omnibuses under the most favourable conditions, to be at 2½*d.* per mile. Theirs was not estimate but actual experience. The directors had also taken out a patent for twin tyres and had also patent rights in improvements for mechanism for driving, braking and spragging motor cars, all of which they thought would be of great utility and in considerable request by other companies.

Their special motor coach was also of registered design to hold 20 persons, and was not an ordinary omnibus. It was under the 3-ton limit, and could therefore be run up to 20 miles an hour, whereas the omnibuses and other vehicles over that weight were limited to 12 miles. It was entirely of British manufacture, the engine being a specially designed 6-cylinder type, of 50 h.p., built by a well-known and leading engineering firm. These engines were of the slow-running order, whereby vibration and noise were greatly minimised. The wood used in the construction of their car was fire-resisting. Their first new coach would be delivered, they were promised, in time to be exhibited at the Motor Show at the Agricultural Hall in March.

In reply to questions, the chairman stated that although only 4,608 shares had been taken up out of an expected 13,000, this would not interfere with the company's programme, and that they were in a position to put from ten to twelve of their coaches on the road, having already eight on order. There was quite a possibility of their getting thirty running, in spite of the capital not having been fully subscribed.

THE Enfield Cycle Company, Limited, propose forming a separate company under the title of the Enfield Autocar Company, Limited, for handling the motor section of the business. The new company are to acquire the works at Hunt End.

THE fire which occurred at the Rover Works last Saturday, we are informed, was not of a very serious character. It is likely, however, to affect the prompt delivery of cars promised for this and next month. The fire has, for the time being, disorganised the material stores, and until the disorganisation is remedied, the Rover Company, Limited, seek the indulgence of their many clients.

COMMERCIAL POINTS.

Recreation for Motor Car Workers.

LARGE industrial companies having factories situated in the country usually set aside a special mess-room for the use of their employees at meal times. At the Crayford (Kent) Works of the Wolseley Tool and Motor Car Company, Limited, this idea has, by the energy of Mr. L. Silverman, works manager, been extended so that the opportunities which the possession of such a room affords for social evenings are taken full advantage of. The whole of the necessary fittings and furniture, we learn, have been purchased with the proceeds from the small nominal charges made for attendance and cooking the staff dinners, at the same time leaving a good balance at the bank sufficient to meet all expenses in the organisation of any special functions. The hall, which is now excellently furnished, is the headquarters of a gymnasium and sports club, while a works orchestra provides musical selections at the dances and social evenings which are a regular feature of the winter programme.

Mr. J. D. Siddeley, General Manager of the Wolseley Company, occupied the chair at a smoking concert given at the works when the gymnasium competition awards were presented. In calling attention to the great amount of good which systematic physical training does for young men, Mr. Siddeley announced his intention to present a challenge trophy for competition next season, and trusted that the *entente cordiale* between the Crayford Works and the Birmingham Works would show itself in the institution of inter-works competitions at sports meetings.

More Steam Commercial Vehicles.

EXTENSIONS are just being completed to the works of Turner's Motor Manufacturing Company in Wolverhampton for turning out commercial vehicles in addition to the Turner-Miesse pleasure cars. These new vehicles, the first of which are intended for 30-cwt. loads or for public service work, carrying 16 to 20 passengers, are designed on similar general lines to the present touring cars—that is to say, they are fitted with "flash" steam generators and engines having three single-acting cylinders. A new type of paraffin burner and a new form of boiler are being introduced. We learn that the successful running of the first of these vehicles has already led to the placing of several orders from different parts of the world—including Japan and Porto Rico.

Motor Chains by the Mile.

SOMETHING like a record order for chains has been given out by the Daimler Motor Company, the quantity being 25,000 ft. of 1¼ in. pitch. This contract has, we learn, gone to the Coventry Chain Company, who for the past two years have supplied all the chains required by the Daimler Company, which has justified the company in placing the present important order. This large order would show that a very largely increased output of motor cars is anticipated, and that Coventry manufacturers mean to take their share of the trade. The Coventry Chain Company are naturally gratified at the placing of this order with them, and are making effective use of the letter giving the order by having photographic fac-similes made and distributed.

HIS MAJESTY KING EDWARD, who is progressive in regard to everything with which he is associated, has recently had one of the well-tried "Castle" trembler coils, for 4 cylinders, fitted to one of his cars.

WE have recently had an opportunity of giving a good practical trial to the special lubricating oil which is supplied by Messrs. De Dion-Bouton, Limited. As already pointed out in the columns of this Journal, the De Dion-Bouton oil is a special lubricant, the preparation of which has resulted from careful tests conducted in these celebrated manufacturers' own works over a considerable period. From our own experience we can say that it fully comes up to the claims made for it, and that those requiring a thoroughly good oil for their petrol cars—for engine and for gearing—can rely upon that supplied by the De Dion-Bouton Company.

MESSRS. W. AND G. DU CROS, who recently opened premises at South King Street, Dublin, have secured the special appointment to the Lord Lieutenant of Ireland.

THE Continental Tyre and Rubber Company have brought out a motor tyre accessory box suitable for private garages and motor car owners, containing repair material necessary in connection with the upkeep of motor tyres; also repair outfits in different sizes, puttees, tyre levers, &c.

THE LIVERPOOL MOTOR HOUSE, LTD., of 6, Atherton Street, South Castle Street, Liverpool, have opened a garage establishment at the above address. The Company are the sole district agents for the Arrol-Johnston cars.

SIR OSWALD MOSLEY, BART., D.L., J.P., the well-known breeder of shorthorns, who is already the owner of a Ryknield and a 6-cylinder Napier, has just ordered from Messrs. C. S. Rolls and Co. a 6-cylinder Rolls-Royce car.

AT the Newcastle Motor Show there were 132 Dunlop tyres fitted.

SEYMOURS, LIMITED, of Knightsbridge, S.W., inform us that owing to the increase in their business they have taken adjoining premises at No. 18, Brompton Road, comprising three floors. They have also decided to open a school of motoring.

THE Continental Tyre Company have received an order from the Daimler Motor Company for three sets of Continental tyres for use on Royal motor carriages.

MESSRS. FRANK LITTLE AND COMPANY, of Newcastle-on-Tyne, have opened a new garage for repairs at Moor Edge, Spital Tongues. The firm are also opening shortly a central motor depôt, showroom and offices at 19 and 21, Westgate Road.

A NEW MOTOR DELIVERY VAN.—A number of these vans have just been constructed for Messrs. J. E. Hutton, Ltd., with a capacity of 10 cwt. The chassis is by Panhard and Levassor, the engine being of the 3-cylinder 8-11-h.p. type. The vehicle is specially constructed for the purpose of a light delivery van and every detail has been studied with the object of minimising complication. A high average speed with full load can be maintained and it is estimated that by means of this van the work of three horse vans or twenty cycle carriers can be accomplished.

NEW COMPANIES REGISTERED.

Andrew King and Company (Limited), Victoria Garage, Shakespeare Street, Nottingham.—Capital, £5,000 in £1 shares. Object, to acquire the business of an engineer carried on by A. King, and to carry on the business of manufacturers, repairers, motors, cycles, vehicles, &c.

British Motor Omnibus Company (Limited).—Capital, £100 in £1 shares.

Cappellen and Freeman (Limited).—Capital, £100 in 1s. shares. Object, to carry on the business of dealers in motor chassis, motor cars, omnibuses, &c.

Deasy Motor Car Manufacturing Company (Limited).—Capital, £150,000 in £1 shares. Object, to carry on the business of motor car, omnibus, and vehicle manufacturers, and to acquire all or any of the shares in H. H. P. Deasy and Company, Limited. First directors, Captain H. H. P. Deasy, Sir Richard W. Griffith, Sir Robert W. Buchanan-Jardine, E. J. Brook, Major Edward de Grey Beaumont, and K. H. Buchanan.

J. T. Ireland and Company (Limited).—Capital, £500 in £1 shares. Object, to acquire the business of motor car and cycle manufacturers and repairers carried on by J. T. Ireland and Company, at Piper's Row, Wolverhampton.

Liverpool Motor House (Limited).—Capital, £500 in £1 shares.

London and Counties Motor Omnibus Company (Limited).—Capital, £100 in £1 shares.

London and Provincial Motor Dispatch Company (Limited), 128, Goswell Road, E.C.—Capital, £10,000 in £1 shares.

London Motor Parcel Express (Limited), 128, Goswell Road, E.C.—Capital, £10,000 in £1 shares. First directors, J. J. Paterson, H. R. Paterson, A. L. Paterson, J. Paterson, and J. E. Carter (all directors of Carter, Paterson and Company, Limited).

North-Eastern Garages (Limited), St. Nicholas Chambers, Side, Newcastle-on-Tyne.—Capital, £50,000 in £5 shares. Object, to acquire the businesses carried on at Harrogate and elsewhere by H. Johnson and Company, Limited, and at Darlington and elsewhere as Leather Brothers, automobile engineers, manufacturers, and dealers, &c. First directors, E. L. Green, H. G. Blackburn, K. J. W. Leather.

Provincial Motor 'Bus and Traction Company (Limited), 3, London Wall Buildings, E.C.—Capital, £305,000 in 300,000 ordinary shares of £1 each and 100,000 deferred shares of 1s. each. First directors, A. A. Campbell Swinton, E. W. Stanyforth, J.P., E. H. Bayley, J.P., and H. Greer.

* * *

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

9376. 4th May, 1905. An Improved Method of Igniting the Explosive Charge in Internal Combustion Engines. Thomas F. Robinson, 52, Market Place, Driffield, Yorks. The object of this invention is to render an engine of this type continuously self-igniting after it has been started, and to enable the continuous use of electrical or accessory means of ignition to be dispensed with. The invention consists briefly in igniting the explosive charge in each cylinder by its direct contact or combination with the flame or heated gases of combustion of a similar charge, which, in a multiple cylinder engine, has previously ignited to generate the working explosion in one other of the cylinders, the working cycle and consequent ignition of which is in advance of that of the cylinder containing the charge which is to be ignited. There are ten figures. Fig. 3 is a sectional plan. The cylinders and their respective pistons and cranks are marked 1, 2, 3, 4, 5, 6. The usual type of valves for the admission of the explosive charge, and the exhaust of the products of combustion, are indicated. 7 are the valve-chambers, connected with their respective cylinders by the passages, 8, the admission valves being marked 9 and the exhaust-valves 10. Ignition-ports 11, 12, 13, 14, 15, 16 connect each valve-chamber with a common ignition-passage 17. The ignition-valves which control the ignition-ports are marked 18, 19, 20, 21, 22, 23. The ignition-valves are controlled by the engine, and may be actuated in any suitable manner, such as by means of cams mounted on a shaft driven by the engine. To prevent loss of pressure from the common ignition-passage, 17, around the ignition-valve-spindles, the latter may work through stuffing-boxes as indicated at 24. The cylinder-valve chambers and common ignition-passage are shown surrounded by a common water-jacket, 25. An electrical sparking-plug, or a plug having a filament which can be rendered incandescent by the passage of a current of electricity, projects into the common passage, as shown at 26.—February 7th, 1906.

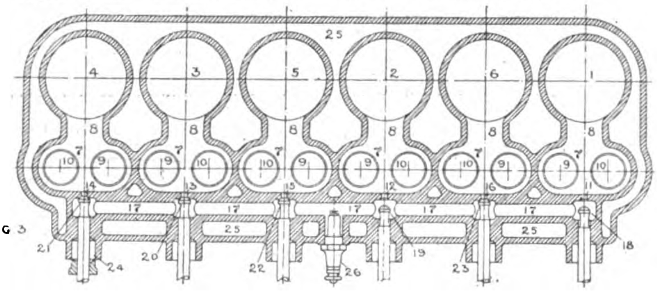

FIG 3

9466 5th May, 1905. Improvements in Two-stroke Internal Combustion Engines. Leethem Reynolds, 6, Westfield Park, Wakefield, Yorsk. This invention relates to improvements in two-stroke internal combustion engines, the object being to provide an improved arrangement of engine, whereby greater efficiency may be obtained, and also one in which the spent gases may be readily expelled from the combustion-chamber prior to the new charge entering therein. There are six figures. Fig. 1 represents a sectional elevation of an engine. A crank-casing, *a*, designed to enclose the main working parts of the engine, provided with a cylinder, *b*, is adapted to be cooled by water or air. The cylinder has a recessed crown, *c*, or combustion-chamber, the recesses, *d*, in which are parallel to the cylinder-axis, and are radially opposite to ports, *e*, in the piston, *f*, which has one end, f^1, closed at f^2. The other end is open and is connected by two gudgeon-pins, *g*, supported at their outer ends by bosses, g^1, on the outside of the trunk and at the inner ends by two connecting-rods, *g*, which in turn are coupled to the cranks, h^1, of the crank-shaft, h^2. Externally this piston is fitted with rings, *i*, to render it gastight against the interior of the combustion-cylinder. Within the outer piston is a trunk-piston, *j*, also with one end, j^1, closed and the opposite end open, which is referred to as the compressing-piston. Rings, j^2, or other suitable means are adapted to make this a working gastight fit in the interior of the driving-piston. Its open end is coupled to a connecting-rod, *k*, whose opposite end is in turn connected with a crank, k^1, on the crank-shaft, such crank having a throw greater than that of the cranks connected with the driving-piston. The compressing piston-crank is set at an angle to the cranks connected with the driving-piston. In the walls of the combustion-cylinder, *b*, is a port or ports, b^1, for the admission of gases, and at the opposite end of the cylinder to the crank-shaft is an exhaust-valve, b^2, of suitable design, adapted to bear against a seating, b^3, and mechanically controlled by a rocking-shaft, lever, and spring, l^3, on its spindle in connection with the crank-shaft, k^2. In the wall of the driving-piston, *f*, is the port or ports, *e*, for the admission and expulsion of the live gases corresponding to the ports in the combustion-chamber.—February 7th, 1906.

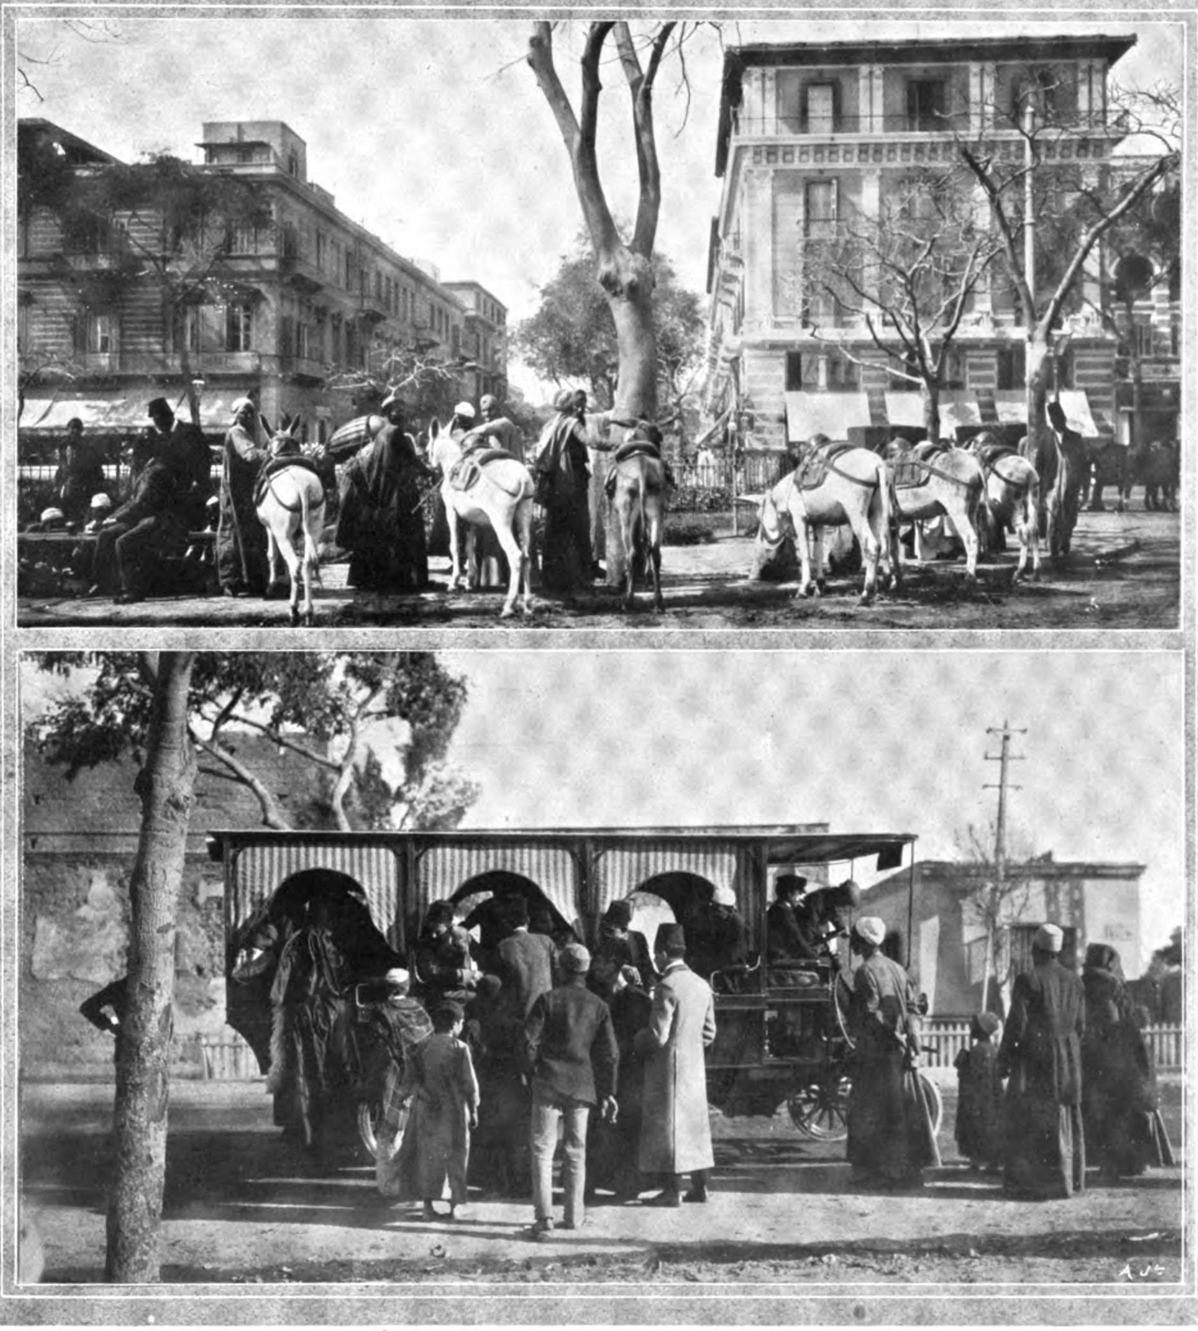
The AUTO MOTOR JOURNAL

A Record and Review of Applied Automatic Locomotion.

No 270. (No. 10, Vol. XI.) MARCH 10TH, 1906. [Registered at the G.P.O. as a Newspaper.] [Weekly, Price 3d. Post Free, 3½d.



CAUSE AND EFFECT.—The introduction of the motor 'bus into Cairo recently has been a source of considerable curiosity to the native Arabs. Although the fares charged are higher than the trams, the service is well patronised whilst the effect on the hiring of the donkeys, seen "making holiday" in the top picture, and so widely used in Cairo, has been very marked. The motor 'bus shown above is a De Dion-Bouton vehicle; one of the journeys made by this conveyance is from the Opera Place at Cairo to the Pyramids, a distance of 14 kilometres, for which only a charge equivalent to one shilling is made.

THE AUTOMOTOR JOURNAL.

PASSING EVENTS.

No Motor Car Act this Year.

In spite of the hysterics and ecstatics of the Highways Protection League, in spite of the weird novels which they have incited enthusiastic ladies to compile, in spite of the Motor Car Commission, whose report is expected at the termination of its labours (as the judges in the Court of Appeal say) "shortly," we believe it is more than probable that there will not be any new Motor Car Bill introduced this year, after all. Of course, we may be wrong, but we base this opinion on an inspired *communiqué* published in a paper which may now be regarded as semi-official. The revelation is made in very discreet language, and there are a good many people who might read it and be quite uncertain as to what it was all about. The passage we refer to is as follows:—

> In view of the statement that the report of the Royal Commission on the working of the Motor Car Act will be issued in a few days, much interest was manifested yesterday in the question whether there would be any new motor legislation this year. The question may confidently be answered in the negative. It is obvious that the Government will have all it can possibly do to carry out its present programme, and if there were any prospect of space there are several matters which would demand this much more urgently than new motor legislation. The Act is working well enough, and the tension which once existed between motorists and the public is fast disappearing. The motor party in the House will therefore have nothing to do this session. The present Act will simply be continued till next year's legislation.

◆ ◆ ◆

The Expiring Statutes Continuance List.

Now if this means anything, it means that the existing Motor Car Act will be placed on the Expiring Statutes Continuance List, a simple method of keeping it in force for another year without trouble or practically any discussion, and one which has paved the way to practical immortality for many a measure which was never originally intended to remain in force for more than a year or two. In fact, an interesting example in point is provided by the old law of 1865, which reduced the speed of self-propelled traction on our highways to 4 miles an hour, and insisted on a man walking in front of the self-propelled vehicle to give warning to approaching horses and carts. This specimen of legislative wisdom was kept alive by being placed on the Expiring Statutes Renewal List from the time it was passed till the date of its partial repeal in 1896.

◆ ◆ ◆

Probably a Good Thing.

The prospect is not altogether unsatisfactory. The Act, we all know, is far from ideal. The speed limit, needless to say, is its principal blot, and there are a lot of minor inconsistencies and incongruities which sometimes are annoying and affect individuals harshly or unfairly, but when all is said and done, the exact effect of an Act depends far more on the method of its administration than on its actual phraseology and wording. And the Act is certainly being just now administered with far less hostility—we might, indeed, say ferocity—than was the case a year or two ago. Every year that passes will see a diminution of prejudice. The friends of the motor are growing rapidly in numbers. Its enemies are disappearing fast, and even county magistrates, in many places, have become votaries of the new locomotion. Above all, the police have been not merely encouraged, but absolutely exhorted under threat of pains and penalties by the new Home Secretary, not merely to tell the truth—a simple virtue which since the coming of the motor many are disposed to think that they have forgotten—but even to state what they may *know in an accused person's favour*. With all these influences working together for good, we really think it is quite possible that we may get through another year with the present Bill quite comfortably, and then perhaps there will be time to thoroughly digest the Report of the Royal Commission, and perhaps make the necessary amendments in the present Act, rather than that a wholly new one should be drafted. It must never be forgotten that "time is on our side."

◆ ◆ ◆

Taxation of Motor Cars.

Of far more terrible import for automobilists than the prospect of the continuation of the present law, are the rumours of increased taxation for automobiles, which are appearing in the daily Press. The authorities are said to be of opinion that a much larger proportion of the taxation of the country should be contributed by the automobile than it at present bears. There are suggestions, too, that the scheme most likely to be adopted will comprise a sliding scale by which cars will be taxed in proportion to their value. If motorists could receive some guarantee that the proposed increased taxation would be accompanied by some guarantee of freedom from what one can only call the blackmail of police court fines, they would probably be readily reconciled to the new arrangement, however unjust they might think it. But we fear there is little prospect of this being the case. The increased taxation will go to the Inland Revenue, whereas the fines collected in police courts go to the relief of the local rates. To make increased taxation of automobiles anything but a monstrous injustice, it should be accompanied by at least two other measures. One of these is that a large proportion of the money furnished by the increase should go to road maintenance, and the other is that the fines collected in local police courts should, as we have systematically advocated, be paid into the National Exchequer, so that the persons who administer the law locally should have no direct object to gain in obtaining as many convictions and fines as possible. If the proposal for increased taxation is really brought into the House of Commons during the present session, or even the present Parliament, it will certainly be incumbent on the motorist Members of both Houses to do their utmost to ensure its being accompanied by these safeguards.

◆ ◆ ◆

Silencing the Motor Cycle.

For years past we have from time to time drawn attention to the nuisance caused by the noisiness of so many motor cycles, and the prejudice which has, in consequence, been created against that branch of self-propelled locomotion. In fact, we are quite certain that had manufacturers been more careful on the point, had they been more considerate both of the nerves of the public and of the rider of the machine, by really supplying adequate exhaust boxes, it would have distinctly benefited the motor cycle trade. Instead of getting less noisy, we believe, as a matter of fact, that the motor cycle has during the past year become noisier than ever. It is with much satisfaction, therefore, that we realise that official notice of the situation has been taken by the Auto Cycle Club, and that at the last meeting of the committee "the question of more effectually silencing the exhaust of a motor cycle" was discussed, and a sub-committee appointed to draw up rules for a silencer competition. It is a beginning, no doubt, and we hope it will lead ultimately to silence. Car manufacturers have found it pay them to make cars as silent as possible, and presumably the manufacturers of motor cycles will ultimately do the same.

◆ ◆ ◆

The "Duchess" of our Canals.

The suction-producer motor barge, "The Duchess," whose triumphant career from London to Manchester we followed in the pages of this Journal stage by stage, has returned safely to her home at Chiswick. On the arrival of the barge at Manchester, we dealt at some length with the various features of her cruise, as reported by Mr. Thomson in the *Standard*, and the lessons to be drawn from them. We pointed out in THE AUTOMOTOR JOURNAL that among the things which the interesting experiment had taught were not only that a motor barge fitted with a suction-producer fed engine could successfully navigate inland waterways at an exceedingly small expenditure of fuel, but that if it was desired to get the best results from a vessel of the kind, our network of canals would have to be considerably improved, if possible widened, certainly deepened, and most of the locks reconstructed. The imperfections of our waterways were known before, but the experiences of the "Duchess" have brought them into greater relief, and have shown that if full advantage is to be taken of the application of the motor to the canal barge, our inland waterways will have to undergo a very considerable amount of renovation. It would, perhaps, be rash to connect the two occurrences as cause and effect, but, at any rate, it is noteworthy that the "Duchess" had scarcely concluded her tour when the Government announced the appointment of a Royal Commission to enquire into the canals and inland navigation of the United Kingdom, to report on their present condition, financial and otherwise, the reasons why private enterprise has not stepped in to improve them, and chiefly as to what improvements and extensions are desirable in order to complete a thorough communication by water between various industrial centres. In addition to these important points the Committee will have to consider the prospect of benefiting the country's trade by reforming our canal system, and the expediency of canals being made or acquired by public bodies or trusts. The enquiries of the Committee will unquestionably take up a considerable amount of time, but there is every reason to believe that the intentions of the Government are serious in the matter, and we trust to see in due course a satisfactory report not merely issued by the Committee, but at no very distant date embodied in practical legislation. Should this be, a splendid field will be opened up to motor boats of all kinds in this country, and a great expansion of the motor boat building industry, particularly in the building of motor boats for transport, may be confidently anticipated.

◆ ◆ ◆

English Canals not the only Sphere.

In this connection, it is of interest to bear in mind that besides the canals and waterways of the United Kingdom the great dependency of India provides an opening for the motor boat and the motor barge on an even more extended scale. From the last Board of Trade returns available—those of 1898—it appears that the total mileage of canals in this country is 4,000 miles. From the paper recently read before the Society of Arts by Mr. Robert Burden Buckly, it appears that in India there are 12,000 miles of main canals and 30,000 miles of distributed channels. Many of these canals, it is true, were mainly constructed for irrigation purposes, but for great lengths they are wide and deep enough for steamers to ply on, and certainly the motor boat, if not the motor barge, might find a wide sphere of usefulness on these. There are, moreover, at least three very important canals in India which have been constructed solely for navigation, and not for irrigation at all, and several minor ones of the same class. It would appear, at any rate, that perhaps more than half of the total mileage of the Indian canals is, or easily might be, rendered navigable, and consequently the day is, in all probability, not very far distant when the motor boat and the motor barge on these extended Indian waterways will prove a genuine blessing to the great dependency.

◆ ◆ ◆

Automobile Responsibility in Germany.

It would seem to have come at last, if we may credit the *Daily Telegraph*, and the report is confirmed by the *Allgemeine Automobile Zeitung*. We refer to the proposal which has been discussed for a long time past in Germany, of making automobilists fully responsible for any injury that may be inflicted by their cars on other people. A Bill, we are told, is to be shortly introduced into the Bundesrath, and then into the Reichstag, which bears a German name the meaning of which is that motor car owners will have precisely the same responsibility towards everybody that a railway company has towards its passengers—perhaps rather more. According to this wonderfully comprehensive measure, the owner of an automobile will have to make permanent provision for the widow and orphans of any person that may be killed by his car, besides bearing the cost of the funeral and any other incidental expenses involved. Where the car has merely inflicted an injury on somebody its owner will be let off more lightly. In that case he will be merely compelled to pay all medical expenses, and support the victim until he is well enough to resume his ordinary avocations. If the person who has been "accidented" by the car happens to have belongings in the shape of a wife and children, it will be the privilege of the happy car owner to defray the cost of their maintenance until their "bread-winner" (we believe that is the charming expression employed in these cases) is well enough to win bread again. Finally, if the victim of a motor car accident is permanently disabled, the owner of the car will have to grant him a pension for life, or make up any deficit in his earning powers which has resulted from the accident.

◆ ◆ ◆

A Premium on Hari-Kari.

The prospect for the automobilist can hardly be regarded as entrancing. So far as we can make out from the information now furnished, and from the discussions which have taken place on the subject in the German automobile press, *the question of contributory negligence does not come in at all.* Apparently, if the victim deliberately runs under the wheels of an approaching automobile and is killed, the owner of the car will have to fit him out with a funeral, and make permanent provision for his widow and orphans. Here is an opportunity for self-sacrifice. Anyone who has so come down in the world that he can no longer support his wife and children, will, if he has a spark of the heroic in him, at once throw himself beneath the wheels of an approaching German automobile—or perhaps better still, a foreign-owned car, and thus make the detested foreigner maintain an honest German family—knowing that he himself will be decently buried, and his widow and orphans looked after in future. There is one small item which the German Government seems to have neglected. It is the sort of thing that one would rather expect from the German character, and that is the question as to what is to happen to the heroic soul who dies for his wife and family if the owner of the automobile under which the self-immolator throws himself happens to be hard up himself. We think, under such circumstances, the Government is bound itself to provide the funeral and the other items, unless they compel every car owner to carry a large shield declaring his solvency, and giving information about his financial condition.

In fact we are not at all certain whether the German Government's Bill, if the Reichstag ever passes it, will not ultimately be destined to revolutionise the ethical code of Europe. To commit suicide under a motor car would be an honourable way out of all your difficulties, and would thenceforward doubtless take the same rank in Germany that hari-kari, the suicide of honour, enjoys in Japan. And it will not be open to the reproach of ordinary suicides.

◆ ◆ ◆

Smashing the Industry.

That there will be a large number of automobilists who also will commit suicide goes almost without saying. When an unhappy car owner has, say, three widows and twelve children dependent on him, and has buried three out-of-work bread-winners who have adopted this method of providing for their families, he will probably take his car and run violently down a steep place into the sea. Seriously, if the German Government force such a measure through it can spell nothing less than disaster for the German automobile industry, of which Germany is so justly proud. Fortunately, the industry commands a sufficient influence, we feel convinced, to prevent the passage of so absurd a measure of injustice. Of course, railway responsibility is one thing, and in the public interest it is particularly far-reaching in Germany, because the State owns practically the whole of the railways. But to fasten a similar responsibility on individual automobilists is a piece of grandmotherly legislation that we cannot for a moment believe has a serious chance of passing into law in a sensible modern State. Can it be that the whole thing is devised to ruin automobilism and prevent it competing with the State-owned railways?

◆ ◆ ◆

The Eternal Problem—London Traffic.

It almost looks as if many of us who are now alive may survive to see a real and effective Hausmannisation of London, a cause which The Automotor Journal has always had deeply at heart and which it has advocated in the past many a time and oft. It does not, of course, do to be too optimistic. When we call to mind that London was once burned down, that a great architect, Sir Christopher Wren, wished to reconstruct it with broad streets and expansive boulevards, that, like nearly all great and far-seeing men, he was overruled by the incompetent mediocrity of his own day, and that London was rebuilt in spite of him on its old silly and stupid want of plan, one is disposed to think that it will be ever thus. Nevertheless, there are now signs of a change, for the pressure tending towards change is becoming tremendous. A very large part of this pressure has been due to the activity and reports of the Commission on London Traffic, particularly the activity and reports of the engineers who have not always seen eye to eye with the more exalted personages whom it was their duty to advise. Another addition to the pressure, and a very substantial addition, too, was provided by Captain G. S. C. Swinton, who, with Sir John Wolfe Barry in the chair, read a paper last week on "London Traffic," before the Society of Arts. Captain Swinton's paper, extracts from which are given on another page, provided a most carefully thought-out treatment of this perplexing problem of the ages, and as is often the case with profound and accurate thinkers, it was full of delightful humour as well as the most drastic proposals. Encouraged no doubt by the Report of the Royal Commission, Captain Swinton spoke of cutting new thoroughfares through London, with a calm insouciance that would have made the hair of the last generation stand straight up on their heads and never come down again. When proposals of this kind can be put before a body like the Society of Arts, calmly discussed there, and find general support, it certainly does seem to indicate that at long last the only possible method of making order out of the terrible chaos of London traffic has a real chance of being adopted some day.

◆ ◆ ◆

A Problem in Two Parts—Will the Motor 'Bus Triumph?

If London, with its enormous annual increase of population, its equally rapidly-increasing business, and its far more than rapidly-increasing traffic, is not to remain the city of dreadful bemuddlement that it is at present, or rather not to become far worse, two things will have to be done. Sensible broad highways, as proposed by the Royal Commission on London Traffic, by Captain Swinton and by others, will have to be driven through the town, no matter at what cost. It is projects of this kind that we have termed above the Hausmannisation of London, from the name of the man who under Napoleon III. performed a service of this kind for Paris. The other thing that it will be necessary to do is to eliminate the horse from London streets. We simply cannot any longer, as Captain Swinton points out, afford to go at the horse's pace, even if there were no other objections than those of a sanitary nature, which every year become more serious. Already sixteen millions have been spent in tubes simply that we may go faster, and how much in laying down electric trams we may *perhaps* know when the Finance Committee of the London County Council sends in its report. From our point of view there is no objection to the tubes. They are out of the way, and for those who like their scenery and atmosphere they form an ideal means of transit between certain fixed points. There remains the electric tram and the motor 'bus. It is between them that the duel for carrying the traffic that we trust before long to see circulating in the broadened and beautified streets of our Hausmannised London, will be waged. We have not much doubt as to which will emerge the victor, and we are glad to find that Captain Swinton, and some of those who took part in the discussion—even electrical engineers who might be prejudiced the other way—were palpably of the same opinion. More than half the benefits of street widening, as we have pointed out over and over again, will be sacrificed if into the widened street is admitted the double row of rails of the electric tram. A city that widens its main thoroughfares at enormous expense, and congests and stops them up with double rows of trams, is forcibly reminiscent of the sailor of the legend, who endeavoured to lengthen his blanket by cutting a piece from the bottom and sewing it on to the top.

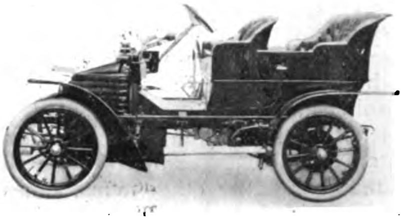
How to Recognise the Cars of To-day.

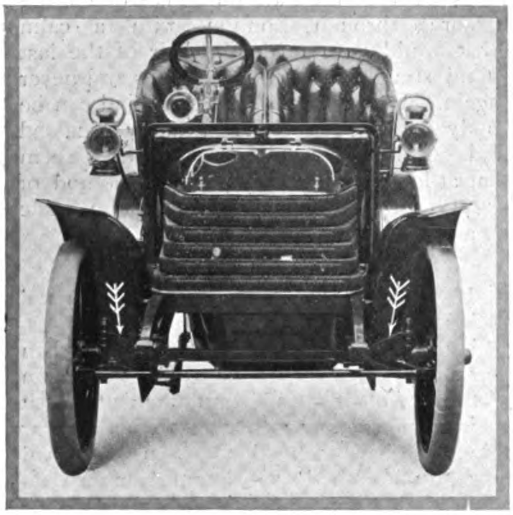
(No. 9).

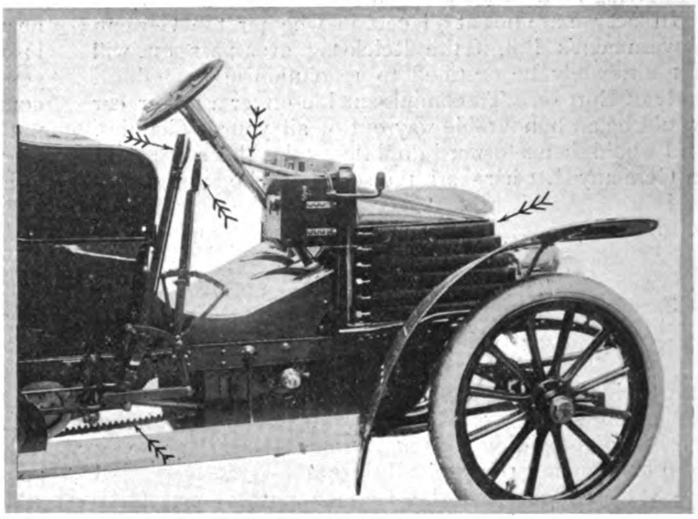
Wolseley Cars.

(BRITISH)

6, 8, & 12 H.P.







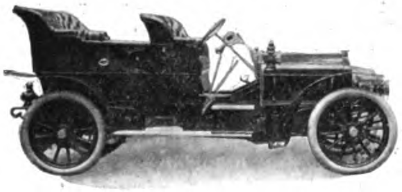
All Wolseley Cars of every age and type can be recognised by the RADIATOR WHICH SURROUNDS THE BONNET. A STAY SUPPORTING THE STEERING COLUMN from the Dash is fitted to all models, and the SIDE LEVERS, which have separate fulcrum points are very distinctive. On most cars the RENOLDS CHAIN is visible beneath the frame, and another constructional peculiarity is the FRONT AXLE.

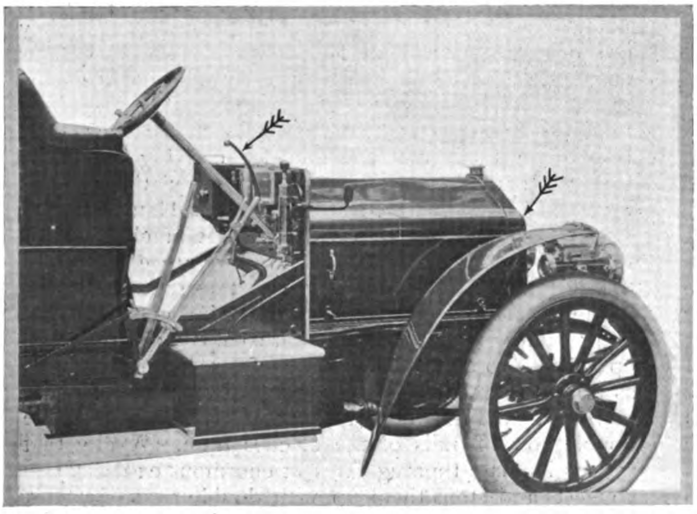
(No. 10).

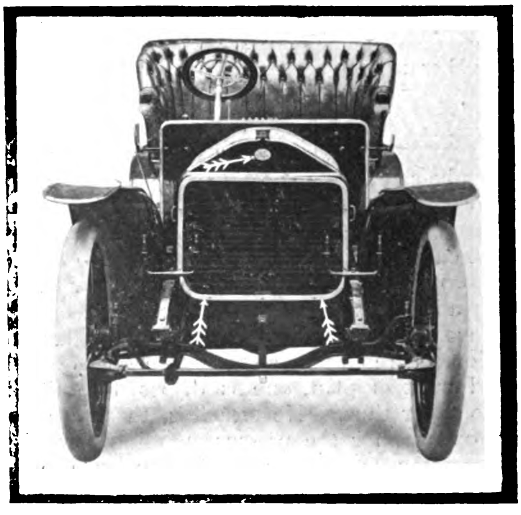
Siddeley Cars.

(BRITISH)

12, 15, 18, 25, 32 & 70 H.P.

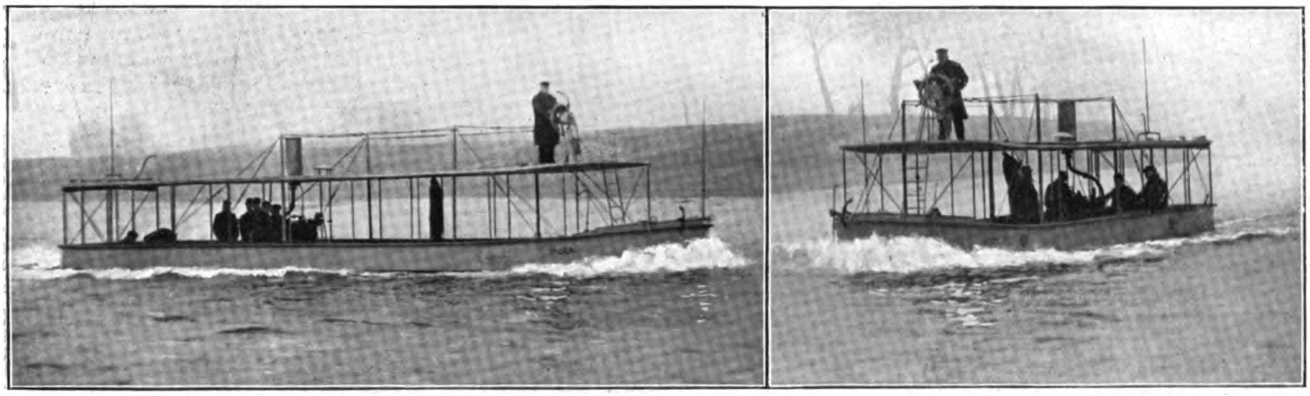






One of the most striking features of these cars is the PLATED BORDER ROUND THE RADIATOR, but the general lines of the BONNET are also very distinctive. Projecting from the Dash, and arranged close to the Steering Column, is the LONG-CURVED IGNITION LEVER, which forms another characteristic fitting on Siddeley Cars.

THE "SPIDER" AND THE "SANDFLY"— TWO SHALLOW DRAUGHT MOTOR BOATS.

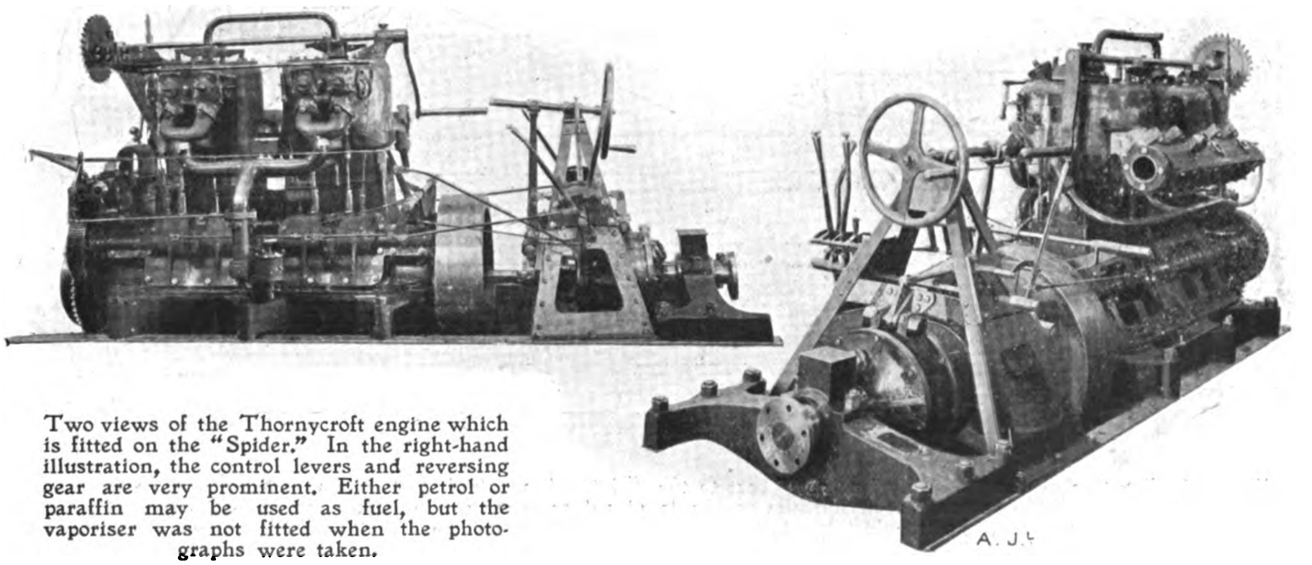


THE "SPIDER."—Two views of Messrs. Thornycroft's new shallow-draught motor boat.

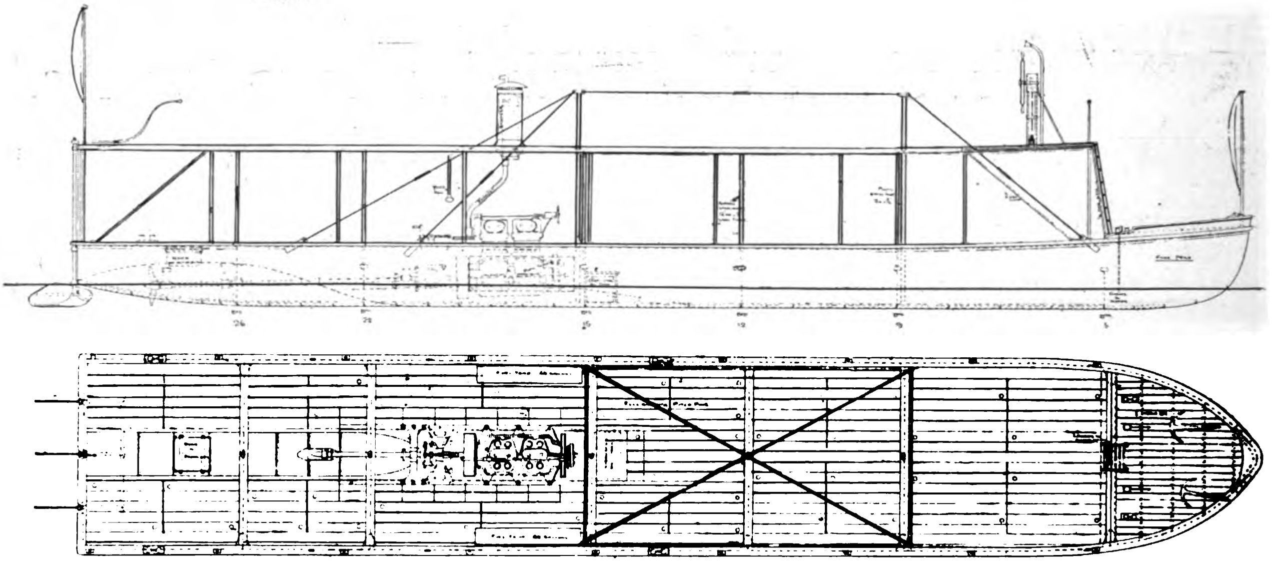
Everyone is aware that there are many important waterways in various parts of the world which are so shallow that boats which measure their draught in anything but inches are quite unable to navigate them. Shallow draught boats are therefore in universal use in many such places, and various improvements have been made in them from time to time in order to adapt them to the employment of modern machinery. Never previously, however, we believe, have boats of this type been fitted with internal combustion engines, and those which have just been built by Messrs. Thornycroft, to the order of the Crown Agents for the Colonies for service in Southern Nigeria, consequently have a very special interest.

One of these is called by the very appropriate name, "Spider," and two of our photographs show the general appearance of this curious looking boat. It has a galvanised steel hull, 56 ft. 3 ins. long with a beam of 9 ft., while the draught when carrying a 4-ton load is only 12 ins. The boat is, of course, practically flat bottomed, but the propellers—of which there are two on the same shaft—are accommodated in a kind of tunnel. So shallow is the draught that the propellers normally lie partly out of water, and it is only the peculiar properties of the tunnel system that is adopted which enables their full area to be effectively used when propelling the boat. A longitudinal section through the tunnel shows that the propellers lie under an arch which drops down to the water line again behind them. They are therefore quite enclosed in a chamber which is sealed all round by the water. Directly the propellers commence to revolve they expel the air from the upper half of this chamber, which immediately fills with water, and remains full so long as the propellers are in motion. In this way the propellers are able to work against a full head of water just as would be the case were they fully submerged at all times. This construction also has the advantages of enabling the propeller shaft to be quite horizontal, and of rendering the propellers very accessible.

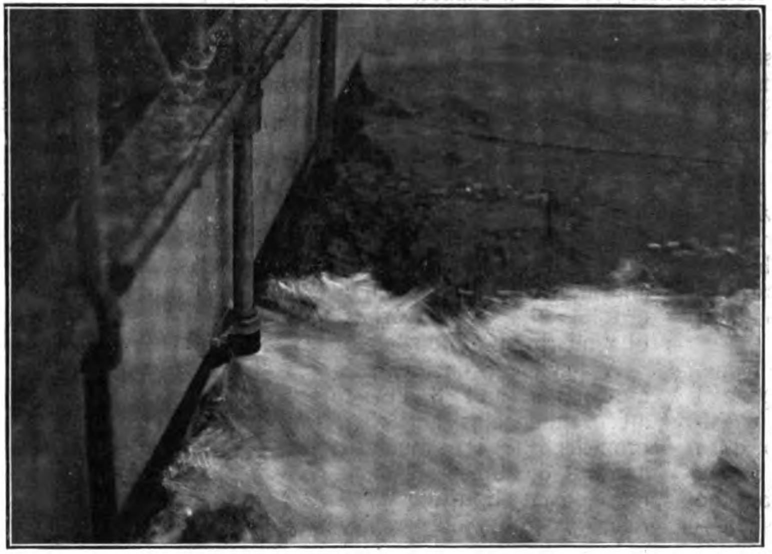
A 4-cylinder engine, of which the bore and stroke are 6 ins. and 8 ins. respectively, is placed just aft of amidships, and this is used to drive the two propellers. It is of much the usual form of construction, and has, combined with it, a reversing gear, as shown in our separate illustrations. At 800 r.p.m. the engine develops 40 h.p. on paraffin, but, as it is intended to run only at 380 r.p.m., only 25 h.p. is usually available. An awning deck is provided, for the boat lies very low in the water, and upon this are mounted the tiller and steering-wheel. There are three parallel rudders, all of which are connected together. Also mounted on the deck is a short



Two views of the Thornycroft engine which is fitted on the "Spider." In the right-hand illustration, the control levers and reversing gear are very prominent. Either petrol or paraffin may be used as fuel, but the vaporiser was not fitted when the photographs were taken.



Plan and Elevation of the "Spider," showing the arched tunnel in which the two propellers work, and the three balanced rudders.

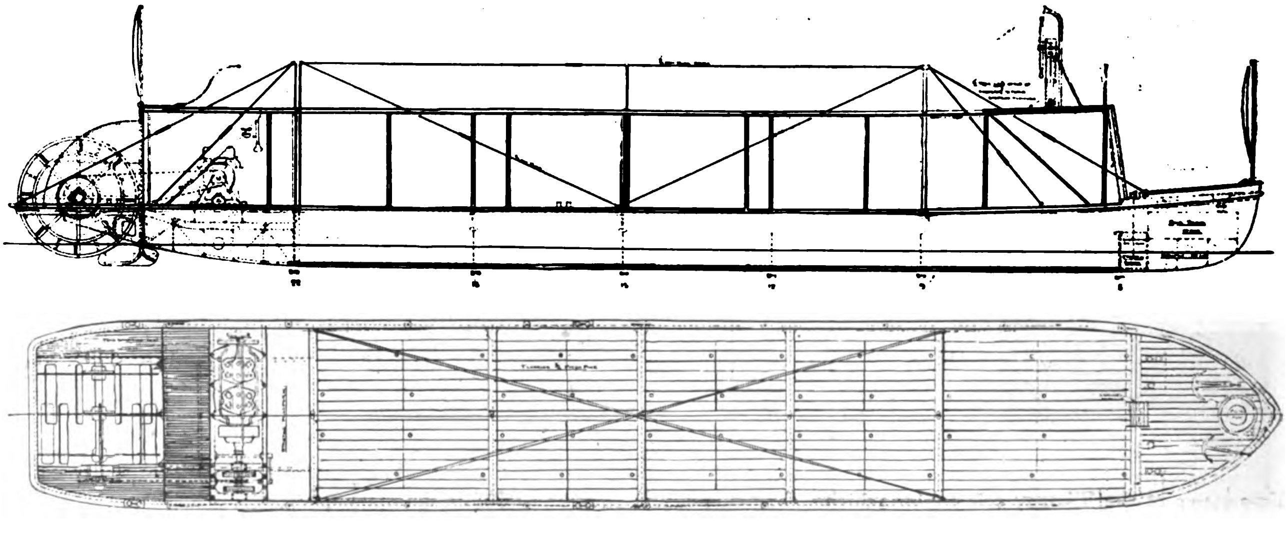


In the wake of the "Spider."—View of the wash from the two propellers, which work in a kind of tunnel beneath the stern of the boat. The small amount of disturbance is very noticeable.

chimney-like structure containing the engine silencer. Fuel is carried in two 40-gallon tanks fixed to the side of the boat.

The sister boat, called the "Sandfly," is of the same overall dimensions, but is fitted with a stern paddle wheel instead of propellers. The general arrangement of the two boats can be compared by the aid of our drawings. It will be noticed that the engine on the "Sandfly" is placed transversely and is right aft; it drives the paddle wheel by a single chain. Already the "Spider" has made a speed of 9¼ m.p.h., which is 2 m.p.h. above the guarantee.

A successful demonstration took place last Wednesday, when the "Spider" carried a large party of Press representatives up the Thames from Westminster Pier to Messrs. Thornycroft's works at Chiswick. On the return journey the engine was run on paraffin.

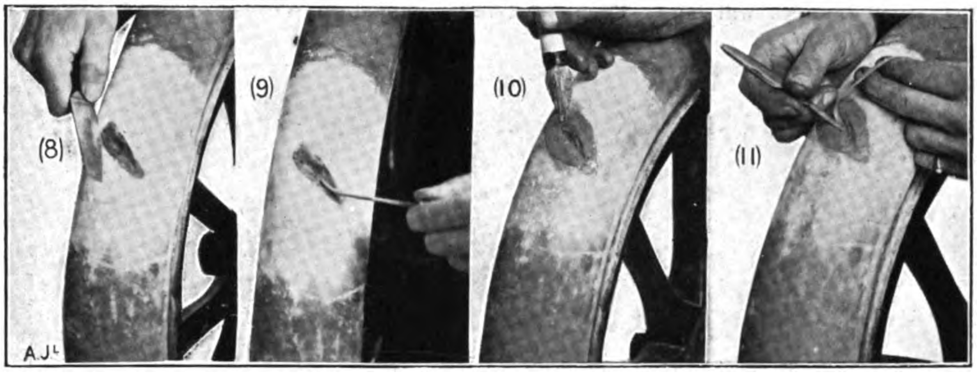


Plan and Elevation of the "Sandfly," a sister boat to the "Spider," and built to the same order. This vessel, however, is propelled by a stern wheel, and the engine is placed transversely to obtain the single chain drive. In other respects the boats, which are to be run under identical conditions in Africa, are similar.

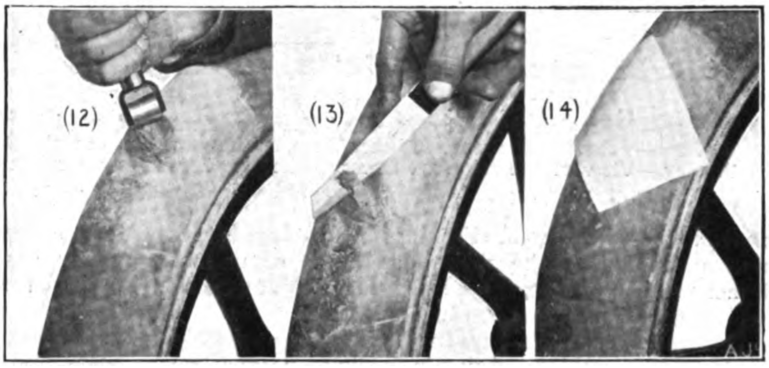
PERMANENT TYRE REPAIR, ON THE ROAD—(*Concluded from page* 256).

The Method of Operation.

PRACTICALLY, it may be said that there are three distinct processes which have to be performed when using the H.-F. Car Vulcanizer—or any other type of H.-F. vulcanizer—and we therefore propose to take each of these sets of operations separately and in order. Before doing so, however, it may be remarked that none of them involves any laborious work on the part of the operator, and that, provided reasonable care is taken, there is no reason why a thoroughly sound and durable repair should not be made by anyone who is willing to devote a little well-spent trouble to the task. The following are the three processes in question: (1) Getting up steam, and so raising the temperature of the vulcanizer to the proper degree of heat; (2) preparing the damaged tyre, ready for vulcanization, by building up the hole with new rubber; and (3) carrying out the actual process of vulcanization. Obviously, the first two sets of operations can be carried out simultaneously if desired, and time would be saved in so doing, but in this case an eye should be kept on the steam-gauge while putting the finishing touches to the tyre repair, and some motorists may even prefer to spend a little more time in order to avoid having to remove the apparatus from the lamp-bracket and fix it to the wheel while it is too hot to be handled comfortably. Such details as these are, however, optional, the main object of this article being that of demonstrating the manner in which each process should be conducted.



Figs. 8, 9, 10, and 11.—Repairing a Tyre. Preparing a Damaged Cover ready for Vulcanization. (8) Bevelling off the Edges; (9) Roughing the Surfaces; (10) Applying the Solution; (11) "Building-up" the Compound.



Figs. 12, 13, and 14.—Repairing a Tyre. Preparing a Damaged Cover, ready for Vulcanization; (12) Rolling down the new Rubber; (13) Paring off the superfluous Rubber; (14) Protecting the built-up repair with covering cloth.

Heating up the Vulcanizer.

Each successive stage, required for "getting up steam," is illustrated in Figs. 2 to 7, inclusive, and our photograph will, we think, be found almost self-explanatory. In Fig. 2, the lamp, E, is being filled with methylated spirit—the wick being thoroughly saturated with it; in Fig. 3, water is being poured into the boiler—the plug, A, having been removed for that purpose; and in Fig. 4, the lamp is being lighted. When filling with water, the cock, C, should be opened, as already indicated, and the operation continued until the water begins to run out through the blow-off snout; the plug, A, should then be replaced and tightened down. In Fig. 5, the lamp has been slid into place, and is being locked by the small screw, E^2—a penny being used to turn it round; on a windy day, in the open, it may be convenient to light the lamp through the hole, E^3, after, instead of before, it has been fixed in place. In Fig. 6, it will be noticed that the shield, E^1, is drawn back clear of the burner so as to allow the full heat of the flame to pass up all the tubes.

Under these conditions, it then takes about seven minutes to get up steam, and for the pressure-gauge to show a reading of about 50 lbs. per sq. in. At this pressure, the temperature of the vulcanizer is that required for the subsequent operation, and consequently it is necessary that the pressure should be maintained at exactly that point. For this reason, the extinguisher-shield, E^1, must then be pushed inward to approximately the position shown in Fig. 7, but should be drawn out a little if the pressure tends to fall, or pushed in a little further if it should rise.

When in actual use, it is extremely important that the correct pressure should be maintained, and in any case—even before applying the vulcanizer to the tyre—it is as well not to allow an excessive pressure to be reached; it is not so much that there is any danger in so doing, because the safety-valve will look after that, but it is undesirable to lose water by permitting any steam to escape.

Preparing the Tyre.

Every operation which has to be performed in getting the damaged tyre ready for vulcanization is shown by a similar series of photographs, in Figs. 8 to 14, to those with which we have just been dealing. In Fig. 8, the large gash which has to be repaired is being trimmed up with a knife—the edges of the hole being well bevelled off; in Fig. 9, the surfaces are being roughened with a rasp—in order to enable the new rubber to obtain a firm hold; and, in Fig. 10, the hole is being painted over with vulcanizing solution. Plenty of time is then given for the solution to dry, for it is essential that the naphtha in which the rubber is dissolved should evaporate while the gas can escape freely, as otherwise there is a risk that small bubbles will be formed in the rubber itself. For the same reason it is very important throughout the whole operation of repair that all moisture should be removed, any trace of water being highly objectionable and detrimental.

After the solution is dry, the building up process should be begun, this consisting in feeding a narrow strip of the special sheet compound into the hole (*see* Fig. 11). The great art at this stage is to pack the plastic compound closely, so that it forms a solid mass, and to avoid imprisoning any air between layer and layer; sometimes it is an advantage to slightly warm the compound, and thus make it even more plastic. This building up is continued until the new rubber stands up slightly above the level of the surrounding walls, and then it is rolled down well, as shown in Fig. 12. Next comes the paring off process, seen in Fig. 13, and then, just prior to applying the vulcanizer to the wheel, a piece of cloth is placed over the partly repaired wound; instead of cloth, paper (preferably glazed) may be substituted, but in either case a little French chalk should be sprinkled over the tyre beneath it.

Vulcanizing the Repair.

Although the actual time taken by the operation of vulcanizing the new rubber is that which occupies longest in practice, yet comparatively little need be said by way of explaining how it is performed. The vulcanizer is strapped on to the outer cover in the manner shown in Fig. 15, the tyre being first deflated slightly to enable the strap to be drawn up quite tight. Then the tyre is pumped up in order to give the necessary pressure against the hot vulcanizer, and the steam pressure is kept steady at 50 lbs. per square inch for a period of 25 to 30 minutes.

During this same time, the inner tube may also be vulcanized, as seen in Fig. 16, the methods employed when preparing it for this operation being those already described in a previous article in THE AUTOMOTOR JOURNAL (Sept. 23rd to Oct 7th last).

At the end of that period, the repair is completed, the vulcanizer may be removed, and the repair then has the appearance seen in Fig. 17. On close examination, the freshly-manufactured portion is found to have the same characteristics as the remainder of the tyre, and if the tyre were to be cut right across, through the patch, the new rubber and the old would be found to have virtually become one.

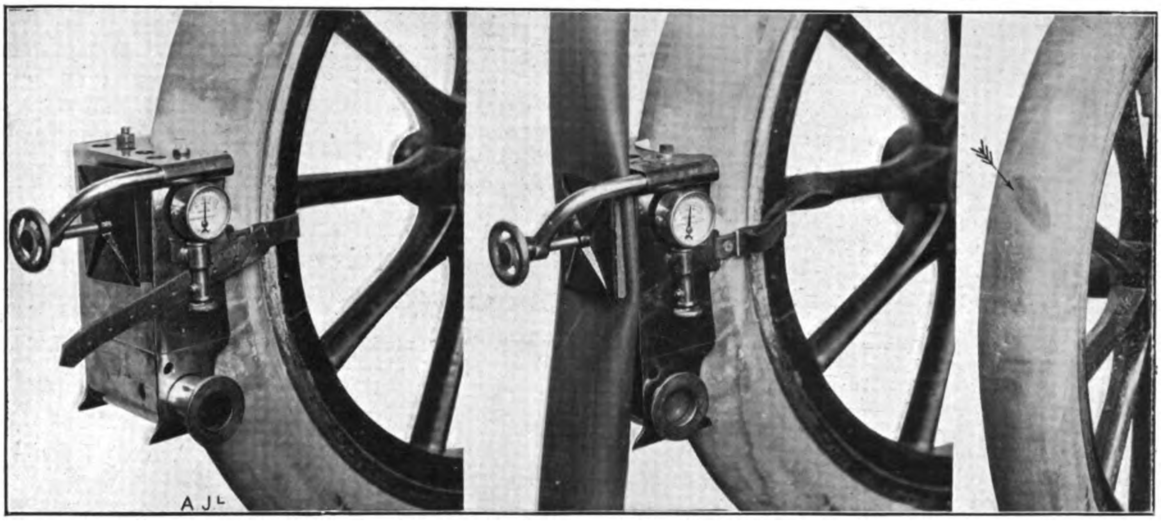


Fig. 15.—Vulcanizing the Repair—the "H.F." apparatus strapped in place.
Fig. 16.—Vulcanizing a repaired Inner Tube, at the same time that the Outer Cover is undergoing the same operation.
Fig. 17.—View of the Repaired Cover. The arrow denotes the re-manufactured portion that now takes the place of the gash.

⊕ ⊕

The Cap Trick.

ANOTHER case of the foolish "last across" business, or something very like it, resulted in the death of Albert Key at Stafford, through being knocked down by a motor car one day last week. The silly little boy had thrown his cap in the road in front of the motor vehicle, and in attempting to pick it up was knocked down, and received the injuries to which he ultimately succumbed.

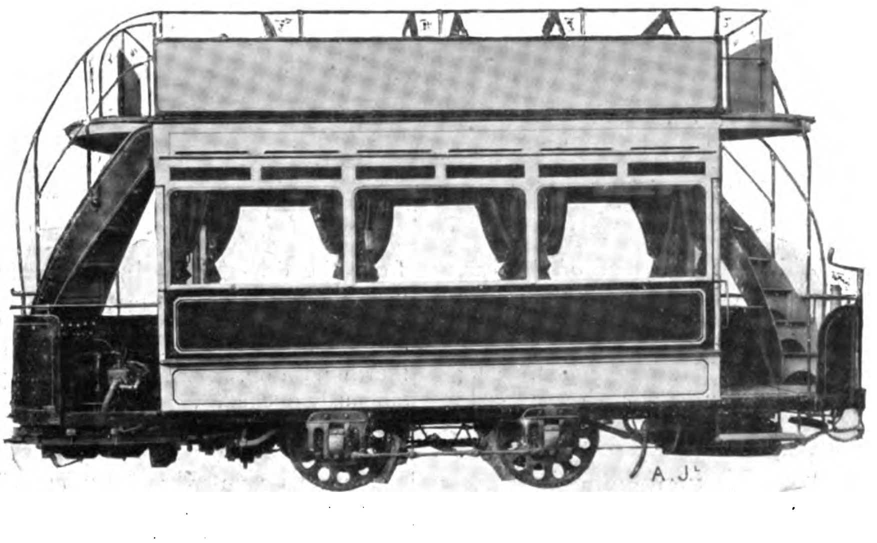
⊕ ⊕

The Advantages of the Motor Lifeboat.

SEVERAL lifeboat stations, as our readers will recollect, have been equipped with motor lifeboats, and at the recent meeting of the City of London branch of the National Lifeboat Institution, Mr. R. Davies emphasised the importance of the superior speed of motor boats for life-saving purposes, and appealed to the public to make a special effort to defray the cost of supplying them.

PETROL MOTOR TRAMCARS.

WHERE the exigencies of the situation render tramcars inevitable, petrol motor-driven machines offer, as we have often pointed out, advantages which would weigh very strongly in their favour, with unbiassed minds, when compared with the orthodox electric installation. Petrol tramcars have had, hitherto, only a very small and isolated field of operation, and there is apparently little immediate prospect of this field extending very widely, so far as tramcars proper are concerned, more especially in view of the increasing popularity of the more flexible motor 'bus. In certain districts, more especially abroad, the tramway serves the purpose of a light railway, and it is in such cases, or where there are no roads at all, that the utility of the tram is especially applicable. Visitors to the Paris Show will recollect a little petrol tramcar constructed by Messrs. Turgan for the service between Trianion and Foret de Rouvray, and it is in such comparatively isolated services as these—and only in such—that it is possible to look upon the introduction of the tramcar, instead of the motor 'bus, with equanimity. In other cases, however, where tramcars, of the horse-drawn type, are already in existence, the petrol-propelled vehicle might well prove a profitable substitute, and one capable of raising an antiquated service to the level of the most modern electric system without the intervention of that appalling disorganisation of traffic which always precedes such a change, or the permanent disfigurement of our highways which generally results.



Petrol Motor Tramcar by the Scottish Motor Engineering Company.

It is interesting to find that a British firm should be building such vehicles; our illustration shows one of the machines recently made by the Scottish Motor Engineering Co., at their Edinburgh works. It is fitted with a 24-h.p. 4-cylinder engine—placed at one end of the frame—which transmits its power to the driving-axle through spur-gearing. A special form of control has been adopted by which the motorman can only drive the car in one direction from each end. When reversing, therefore, he has to go to the other end of the vehicle, and to carry the control-handle with him—which ensures that his forward gear is locked in the neutral position. Bodies capable of seating from 40 to 50 passengers are fitted to this chassis, the overall length of the smaller body being 13 ft. 1 in. Unladen, the vehicle weighs between 4 and 5 tons, and is stated to be capable of ascending a gradient of 1 in 15 with full load.

⊛ ⊛ ⊛ ⊛

TWO MOTOR SHOWS AT OLYMPIA—IMPORTANT DECISION OF THE TRADE SOCIETY.

THE Society of Motor Manufacturers and Traders have, we are officially informed, taken a momentous decision, viz., to exclude commercial vehicles from their annual International Motor Exhibition at Olympia in November next, and to hold a separate commercial show—also at Olympia—early in the following year.

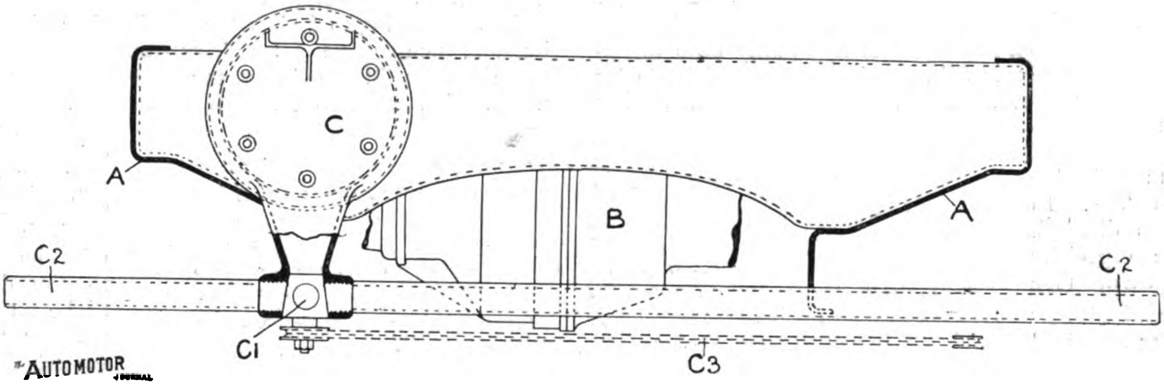
The reasons for this step are twofold. In the first place, at the society's two former Exhibitions at Olympia, there were complaints from both sections of the trade of insufficient space, whilst the large attendance of the public rendered it desirable if possible to increase the gangway accommodation. In the second place, the membership of the society has largely increased, and in spite of the increased accommodation obtained at great expense by improvements in what is known as the Annexe, it was plain that the building would shortly be unable to accommodate even the members, to say nothing of others who desire to exhibit. Moreover, the long-talked-of extension of the commercial side of automobilism is now rapidly developing, and it is no longer possible to relegate these exhibits to a section of another Exhibition. As a matter of fact, at the last Olympia Exhibition, the demand for space in this section was practically as great as for pleasure cars, and it is certain quickly to exceed it.

Under the new arrangement, the November 1906 Exhibition will, consequently, be devoted entirely to pleasure cars and their accessories, which can, therefore, be displayed in a more suitable manner. In April, 1907, the main hall will be filled with a show of commercial vehicles and their accessories. The Annexe will be available for marine motor exhibits, which formerly used to be crowded in amongst large business cars.

Machinery, which, in connection with the boats, makes an interesting feature at the Paris Exhibition, can then be displayed more in proportion to its importance.

THE "AUSTIN" EXHAUST DEVICE.

ON the new "Austin" cars, of which we have already given some particulars, a special device is being introduced for enabling the driver to direct the exhaust gases leaving the silencer, so that they issue out on the "near" side, the "off" side, or at the rear of the car, according as to which is least likely to cause annoyance under the circumstances prevailing at the time in traffic.



Our illustration demonstrates this arrangement, being a transverse section through the new 25-30-h.p. live-axle car, which, as will be noticed, has a specially-shaped pressed steel frame, A, and in which the silencer, C, is placed longitudinally just in front of the axle casing, B. Beneath the silencer, C, is a four-way cock, C^1, controlled from the driver's seat by the chain, C^3, and from this cock the two pipes, C^2, project out to each side of the car. The cock not only enables the exhaust to be emitted in either of the three directions, but has also a fourth position, in which all three passages are simultaneously opened.

* * *

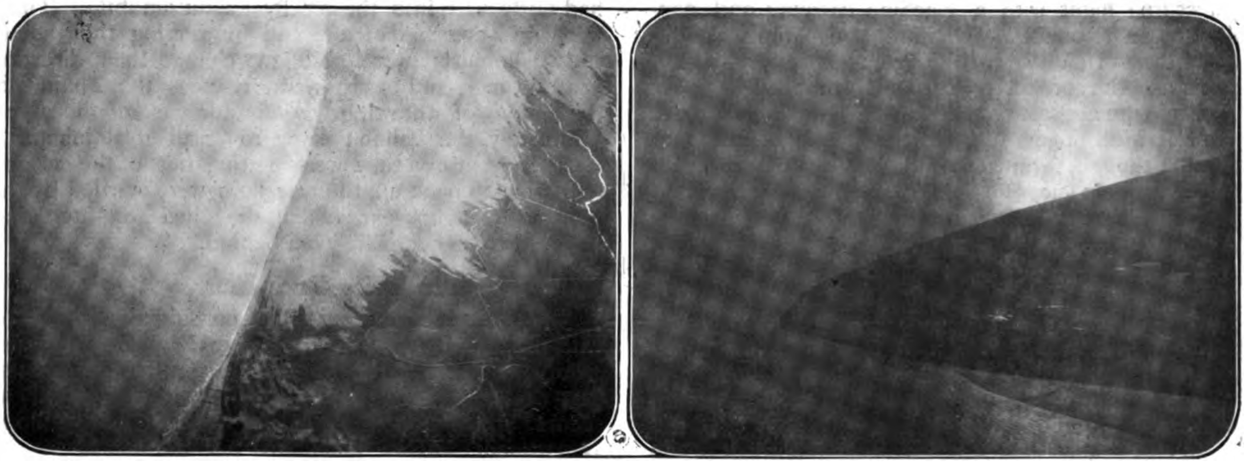
Old Friends—or Startling New Inventions?

IT is really very remarkable how often the same thing is invented and re-invented time after time, at what would be, in the case of any other industry than the automobile industry, quite frequent intervals, and it is perhaps an even more striking commentary on the limited extent to which the doings of inventors in the past are studied by present-day workers that so many re-introduced devices are looked upon as being entirely novel. One reason for this is doubtless to be found in the fact that the development of self-propelled vehicles has been extraordinarily rapid, in spite of the enormous amount, and the very varied kind, of knowledge that has had to be accumulated in so short a period. Whatever may be the cause, however, it has of late been even more marked than ever, and amongst the cases that have come before us within the past week or two are some notable instances that are worthy of passing mention. The Crépet change-speed-gear, for instance, has been spoken of lately in several of the French automobile papers as though it were not only entirely novel, but were destined to completely revolutionise present-day practice. The mechanism itself is, however, little more or less than that which was fitted to the cars made by the Motor Manufacturing Company a few years ago—the "Iden" gear—of which we gave a fully illustrated description on October 11th, 1902. All the wheels inside the gear-box remain in mesh with one another, instead of being brought into gear successively as they usually are, and all the wheels on one of the two shafts are normally free to revolve idly upon that shaft, while the shaft itself is fitted with keys that can be slid along from wheel to wheel, in order to lock anyone of the wheels at a time to it. Such, too, is the Crépet gear, in which ball-bearings are interposed between each of the wheels on the lay-shaft, and in which the shaft is moved bodily endways, with its projecting keys. Other "re-inventions" that have been referred to lately in this country are the "Lucas" and the "Lege" petrol engines, the former being constructed with two inter-geared crank-shafts, like the Tourand motor (*see* AUTOMOTOR JOURNAL of July, 1900, p. 511), and the latter having what we termed a "wobble" gear, when describing a similar—and a nearly as complicated—steam engine on August 30th, 1902. In America, curiously enough, a two-cycle engine—the "Lombard"—has also been designed lately on somewhat the same lines, but in that case the cylinders revolve as well as the power-shaft, and in this respect the engine is, to a certain extent, like a petrol engine that is now being experimented with by Mr. Lamplough, of the Albany Manufacturing Company, at Willesden.

The Automegaphonomobile.

AMONG the portents which Londoners and visitors may expect to see on the streets of the Metropolis this summer, will be a number of motor char-a-bancs or wagonettes filled up with American tourists and taken round all the principal thoroughfares of the Metropolis. They will be instructed by a typical showman learned in the lore of the town, who, to make his remarks fully comprehensible to the rapidly moving audience behind him, will spout forth history, archæology, topography, politics, society gossip, and miscellaneous information with, as Byron said, "a forty-parson power" through a megaphone with which he is to be armed. It is adapting New York methods to London City, and those who have gone through similar experience in New York have been absolutely astonished and their brains set in a whirl by the extraordinary amount of anecdote, information, and jocularity which has been poured into them through the megaphone. It will be an entertaining sight and a tribute in a way to automobile development as well as to the powers of the megaphone man.

AERONAUTICS.



The sand-swept land of Dungeness.

Last sight of England, showing Dungeness and the setting sun on the sea.

THE LAND AS SEEN FROM A BALLOON. Photographs by Mr. Spencer.

From the Heights.

To bring home to our readers how vastly different familiar objects appear when seen from the heights to which a balloon attains, we reproduce on this page several photographs, for which we have to thank Mr. Frank Butler and Mr. Spencer; these views were secured on the cross-Channel journey which we described last week. Taken in their natural order, they display a birdseye view of Romney Marsh and Hythe—Romney Marsh so dear to Barham, the author of the "Ingoldsby Legends," though probably even he would scarcely recognise it as here shown. The river had overflowed its banks, and looks somewhat like the photograph of an electric discharge. The long straight white line is the celebrated military canal that runs across Romney Marsh from near Ore past Winchelsea to near Hythe. It was the invention of the great Pitt, when Napoleon threatened to invade the country. The French were certain, he thought, to land on Romney Marsh, and the canal was excavated in order to provide a second line of defence. Barham made great fun in one of his stories of this idea, that the French, who had crossed half the rivers in Europe, would, if they once landed, be kept back by a 30-foot canal.

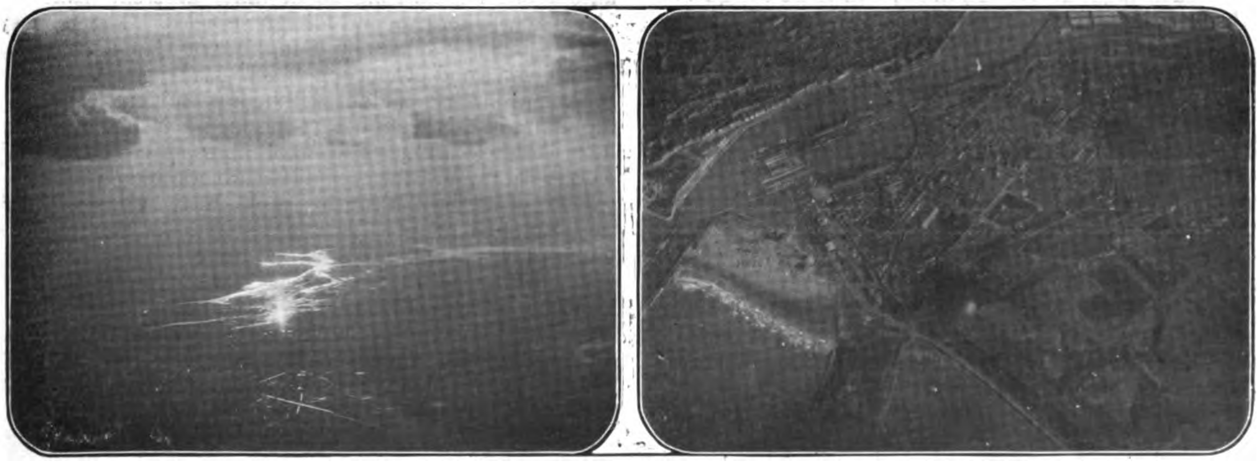
The next photograph represents a birdseye view of Dungeness with its sands, producing a very curious effect.

In the next photograph the balloon, leaving England, has descended to a considerably lower altitude, and the headline of Dungeness looms black against the setting sun.

Finally, the concluding view shows the first glance at Boulogne from high above the Channel.

Death of Professor Langley.

Everyone interested in aeronautics, particularly the heavier-than-air branch of the art, will learn with regret of the death of Professor S. P. Langley. Professor Langley was one of the most enthusiastic experimenters with aeroplane models, and it was with one of these, driven by a small steam engine, that a free flight of about a mile was executed over the Potomac River in 1896. This machine, it will be recollected, consisted of two aeroplanes with di-hedral angles separated from one another by a certain space in which two propellers revolved, the whole machine being guided by a poly-



The Military Canal and overflowing rivers near Appledore.

Boulogne as seen from aloft.

THE LAND AS SEEN FROM A BALLOON. Photographs by Mr. Spencer.

hedral tail. The motor developed 1 h.p. Professor Langley was less successful when in 1904 he endeavoured to effect free flight with a machine carrying and controlled by an aeronaut. The intrepid experimenter who mounted the machine was the Professor's assistant, Mr. Manby, and the aeroplane, which was launched, or rather hurled into the air, from a landing stage on the Potomac River by a kind of catapult, almost immediately fell into the water, though, fortunately, Mr. Manby was uninjured. One cannot help surmising, in the light of more recent experiences, that this violent launching of the machine was probably largely responsible for the want of success. If a machine is capable of maintaining itself in the air it ought to be capable of rising from the ground into the air if mounted on a suitable carriage, whereas if hurled into the atmosphere at a high velocity, stresses and pressures are developed which render the conditions totally different from those under which the machine can maintain its equilibrium. Professor Langley was not only an experimenter, he was a writer and student of the principles of aeronautics and contributed a valuable amount of work towards the solution of the problem. By means of a large whirling apparatus, by which the lifting power of aeroplanes arranged at different angles could be measured, he discovered the fact with which his name will be permanently associated, that the faster an aeroplane is driven through the air, the less energy is required to keep it afloat.

Salomons Prize.

THE Technical Committee of the Aero Club have settled the general conditions governing this competition. The competition will take place in England this year, under rules to be drafted by the A.C.U.K., in accordance with the general regulations of the Fedération Aéronautique Internationale. It will be open to subjects of any country, and will be for machines of the heavier-than-air type, propelled either by human or mechanical power; every machine must carry at least one operator. The prize will be a 100 guinea Cup, presented by Sir David Salomons, Bart., and a money prize.

Invitation to the Brothers Wright.

THE Aero Club are inviting, through the Aero Club of America, the Brothers Wright to visit England in the summer, to give a demonstration of their flying machine, with which they recently accomplished a non-stop circular flight of over 24 miles, and to be the guests of the A.C.U.K. during their stay.

Historical Pictures for the Aero Club.

SIR DAVID SALOMONS, BART., a life member of the A.C.U.K., has presented to the club some historical framed prints on ballooning, which will be hung in the Club Room, at 110, Piccadilly, W.

Gordon-Bennett (Aeronautical) Cup.

To compete in this race for spherical balloons, which is announced to take place on September 30th, starting from the Tuileries Gardens, Paris, seven countries have entered, viz., France, Italy, Germany, Spain, America, Belgium, and Great Britain. Each country is allowed a maximum of three balloons only.

Motor Car *versus* Balloon.

AN amusing competition, perhaps we might almost say as far as this country is concerned a revival, of the sport of balloon hunting by motor car, was carried out on Saturday last, when the Aero Club's "Vivienne" made an ascent from Wandsworth, pursued as soon as it had fairly risen into the air by an automobile. There were cross-currents of air, and by varying their height the balloonists were able to change their direction several times, and to cross and re-cross the Thames in the hope of throwing the motor car off the scent. Ultimately, the balloon came to earth at Rainham, in Essex, and just as they were getting out of the car and preparing to pack up, the travellers were startled by the hoot of the motor car, which they had forgotten and believed to be completely left behind.

Count Zeppelin Tries Once More.

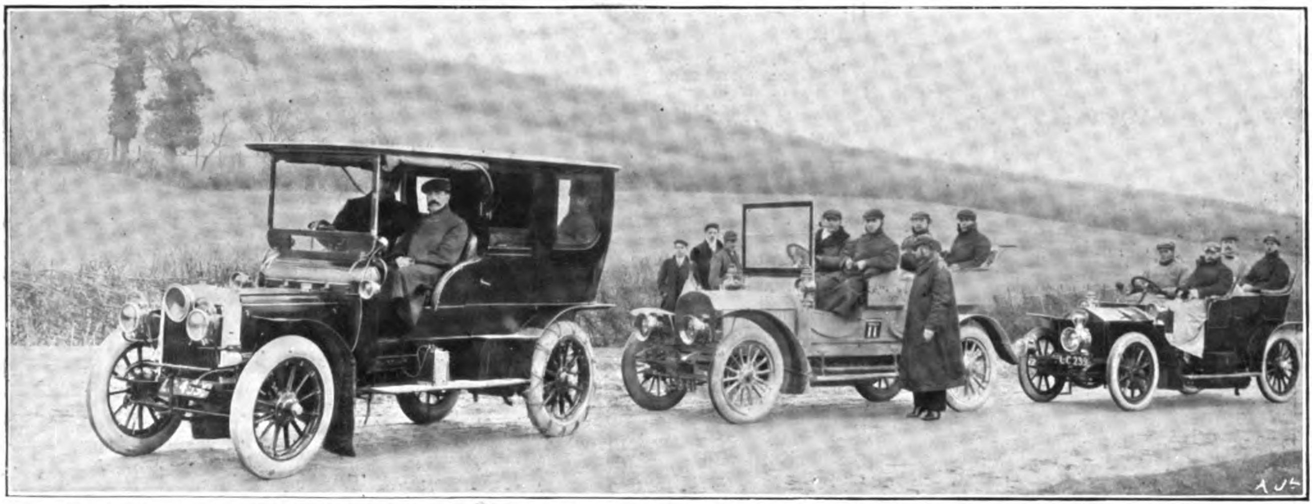
NEARLY everyone must feel considerable sympathy with the aged German experimenter, Count Zeppelin, and nearly everyone will be pleased to learn that he is not so cast down by the failure of his recent experiment as seemed at first to be the case, the German Army Balloon Department having come to his assistance, as we mentioned recently, and the War Office having arranged to assist him with all the necessary materials, a large staff of experts and workmen, and everything required to build another airship on improved lines. It is to be smaller than either of its predecessors, but it will, we understand, have greater motive power, and Count Zeppelin and his engineer, Herr Durr, are already at work on the plans for the new machine. No doubt this is Germany's answer to France, for the success of the Lebaudy airship and the military efficiency which has been accomplished with that splendid piece of design, has awakened a strong spirit of rivalry across the Rhine. Count Zeppelin's previous designs must, it would seem, be now regarded as demonstrably imperfect in principle. Probably the general outline will be completely remodelled, and we shall certainly not be surprised to learn that some of the general principles of construction adopted in the Lebaudy airship have been copied in the German machine.

* * * *

A Canadian Motor Show.

VERY strenuous efforts are being made in Canada for the holding of what promises to be a most successful automobile and motor boat show at Toronto, from April 7th to April 14th. Already sufficient exhibits have been assured to fill the entire space devoted to automobiles, comprising about thirty different makes of Canadian, American, and foreign vehicles. The keenest interest is being taken by a number of Canadian firms, including a good proportion of accessory dealers. Motor boats and marine engines will be a prominent feature of the Show, in this section a 31-ft. speed boat being shown by a Toronto firm. The total floor space comprises 24,000 sq. ft., and the committee are adopting a uniform scheme of decoration for the whole show, in like manner to the system adopted at the recent New York shows. Uniform signs will be provided to exhibitors without cost. Altogether the enterprise shown by the committee responsible for the organisation should help forward very materially the industry in the Canadian Dominion. A similar Show is, moreover, it appears, to be held in Montreal from April 21st to 28th. We shall hope to learn that, prominent amongst the exhibits at both exhibitions, will be found some models of the leading makes of British manufacturers. Hitherto the American makers seem to have almost entirely captured the Canadian trade.

TYRE, LAMP, AND SPEEDOMETER TRIALS.



THE A.C.G.B.I. TYRE, LAMP, AND SPEEDOMETER TRIALS.—The three cars on which the competing devices are fitted. On the left is a 28-h.p. Daimler, in the centre is a 20-h.p. Dennis, and on the right is a 20-h.p. Rolls-Royce. All the cars are shod with Collier tyres of different sections, and each car carries one or two speed indicators and one or more lamps. The Dennis car itself has also been entered for a test of reliability, but the performances of the other vehicles will not be recorded.

THIS interesting trial, which is being carried out by the A.C.G.B.I., is now in full swing; the three touring cars, loaded with the devices under test, having started their road trial on Thursday, March 1st, after having gone through preliminary tests in the garage. One of the cars—a 20-h.p. Dennis—is itself undergoing a trial of reliability, but the other two, which are respectively a 28-h.p. Daimler and a 20-h.p. Rolls-Royce, are not being observed as to their performance.

Collier Tyres.

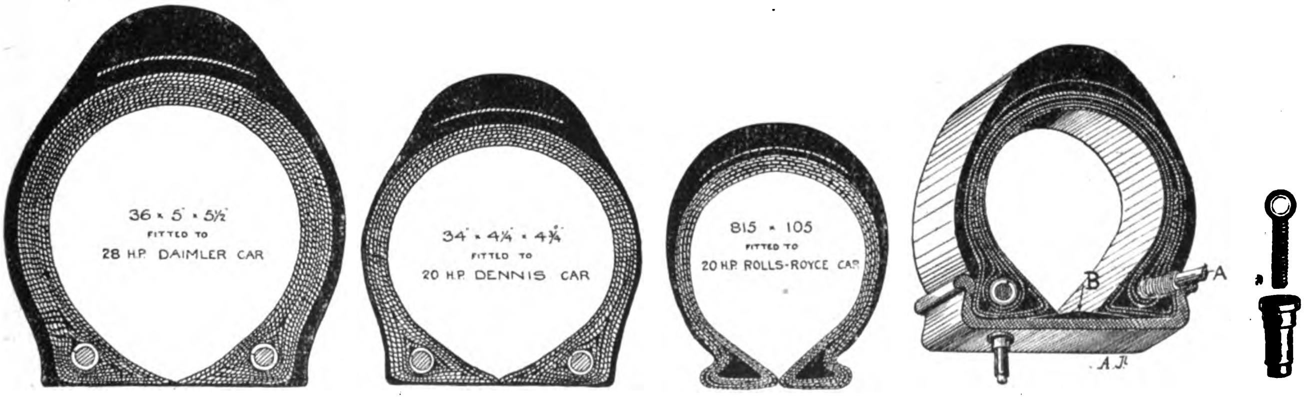
All of these three cars are shod with Collier tyres, but the section of the tyres on the respective vehicles differs in size and shape, as illustrated by the three accompanying line drawings. Those on the heaviest vehicle—the 28-h.p. Daimler—which weighs about two tons when loaded, are 5 ins. wide, but they measure 5½ ins. from tread to base owing to the great thickness of rubber in the tread. On the Dennis car, the corresponding measurements are 4¼ ins. and 4¾ ins., so that the additional half inch of tread still remains.

Both these sections have the well-known Collier attachment by which the tyre is secured in place by numerous small eye-bolts and nuts. The eye-bolts pass through the rim, and are threaded over steel rings which lie in wire-lined tubes inside each bead. This construction is very clearly illustrated by one of our drawings, which shows part of one of the steel rings, A, projecting from its channel. Another peculiarity to be noticed is the wedge-shaped rubber strip, B, which lies on the bottom of the rim, this filling the space between the edges of the beads. On the Rolls-Royce car, the tyres are of an "experimental" Collier type, for they have beaded edges, and their section lacks the extreme thickness in the bead.

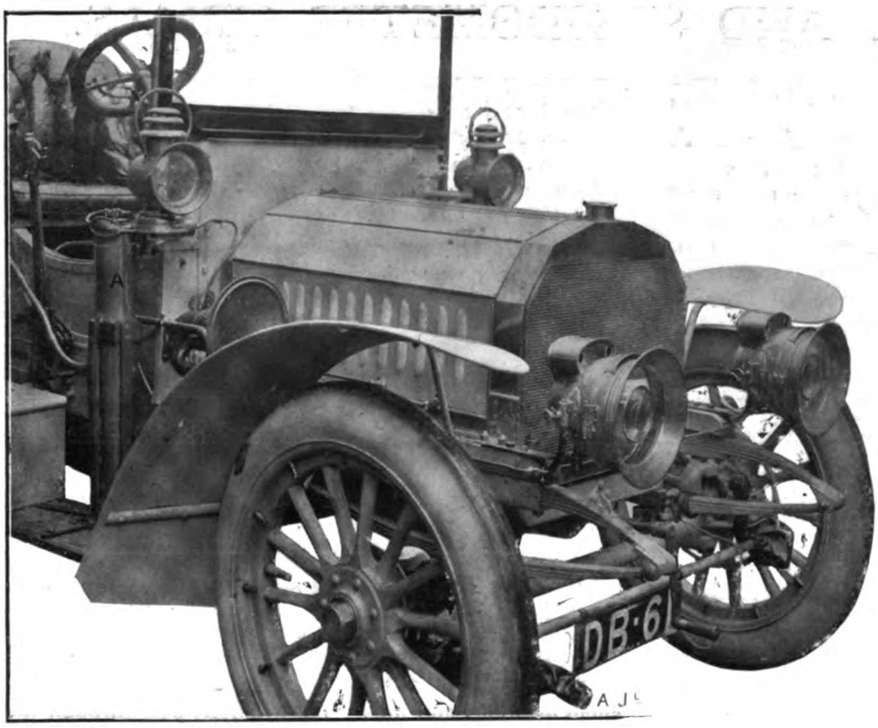
In addition to the Collier pneumatics, a set of Hartridge solid tyres, fitted to a 'bus chassis, has also been entered, but this vehicle has not yet started with the other cars, and the total distance it is required to run is less.

Lamps.

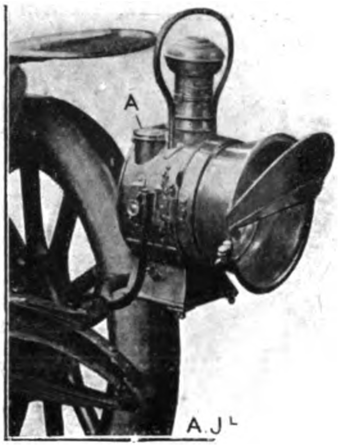
Only two headlights are competing, one entered by Worsnop and Co., which uses acetylene, and the other by Polkey, Limited, which burns paraffin oil. Of these, the former is peculiar for its generator, which, as is evident



THE A.C.G.B.I. TYRE TRIALS.—Sections of the Collier Tyres which are fitted to the Daimler, Dennis and Rolls-Royce Cars. The two larger sections are of the well-known Collier pattern, but the smallest section is that of an "experimental" set, having beaded edges and thinner tread. On the right is a section showing the construction of the standard Colliers, as also one of the small eye-bolts which are used to secure the tyre in place.



THE A.C.G.B.I. LAMP TRIALS.—View of the Worsnop Acetylene Headlights and Generator fitted to the Dennis Car. The Generator, A, —alongside the dash—is encased in a long cylinder. This cylinder, it will be noticed, is of comparatively small bore, and one result of this is that the surface of the carbide in contact with the water is not, therefore, unduly great when the generator is idle.



THE A.C.G.B.I. LAMP TRIALS.—View of the Polkey Headlight. This lamp consumes paraffin and is fitted with a long glass chimney. Two spare chimneys are carried in pockets, A, formed in the lamp casing. On the lamp illustrated, a reflector, B, has been added in order to enable the observer to see that the lamp is alight in the daytime —the trial taking place, of course, during such times as the car is running.

from our illustration, is very long, being enclosed in a narrow tube some 30 ins. in height. Owing to the shape of the retaining vessel, the area of carbide on which the water acts when the lamp is at rest, is comparatively small.

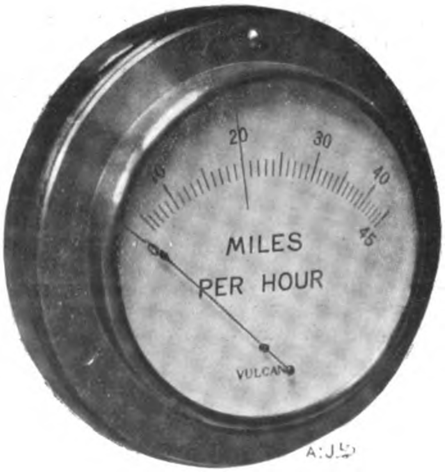
THE A.C.G.B.I. LAMP TRIALS.—View of the Metallic Mirror Company's Tail Lamp. This device is entirely self-contained, and consists of a rectangular box lined with reflecting material and faced with a red window and transparent number plate. Owing to the internal arrangement, the light is evenly diffused, and the lamp is also well protected.

The Polkey headlight, of which we also give an illustration, is constructed on the principle of an ordinary domestic paraffin lamp, and it has the usual glass chimney over the burner. In case of breakage, two spare chimneys are carried in tubes constructed for this purpose in the body of the lamp.

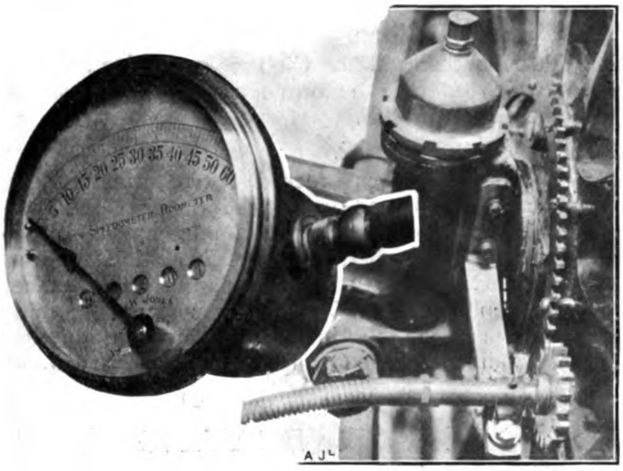
There are also three tail lamps in the trial, one of them has been entered by Messrs. Worsnop, who entered a headlight, another by Messrs. Ryta and Hoult, and the third by the Metallic Mirrors, Ltd. This last is a very neat arrangement, for it combines a red light and transparent number plate as a complete unit. The lamp is enclosed in a rectangular box which is lined with metal reflectors, so that the light is evenly diffused throughout the interior.

Speedometers.

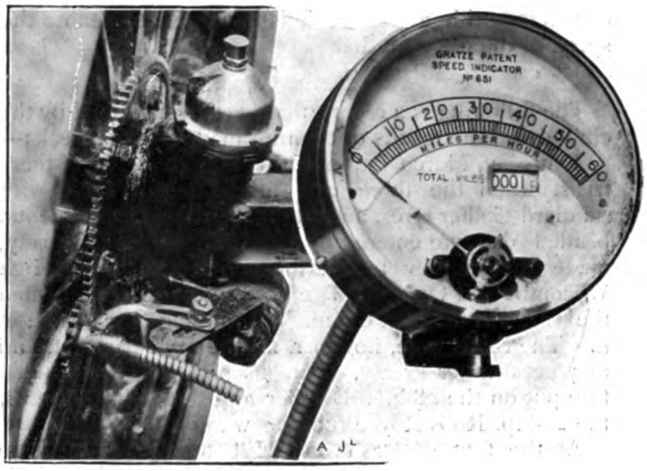
Quite a number of these instruments have been entered, but as there are so few vehicles to test them on, only five instruments are at present under trial, and the remainder will, therefore, be fitted during the latter period of the trials. Those now in use, of which we give photographs, are the Jones, Gratze, Vulcan, Cowey, and Warner. They represent a diverse selection of principles, and include examples of the mechanical, magnetic, and electrical types. THE AUTOMOTOR JOURNAL series of articles on the subject of speed indicators—part of which has already been reprinted in book form in the series of the Automotor Library—has already dealt thoroughly with so many of the instruments now on the market, that only a brief reference to the instruments mentioned above will be necessary. In every case one of the front road wheels has been the place selected for the attachment of the driving



THE A.C.G.B.I. SPEEDOMETER TRIALS.—View of Vulcan Speed Indicator. This is an electric instrument, the indicator itself being virtually a hot-wire voltmeter which records the electric pressure generated by a little magneto driven from one of the road wheels.



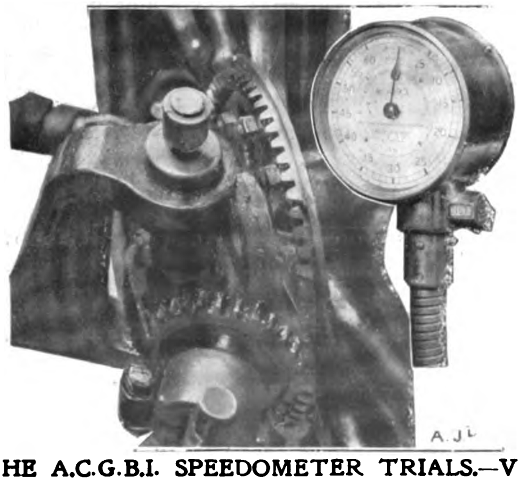
THE A.C.G.B.I. SPEEDOMETER TRIALS.—Views of the Jones Speedometer and its driving gear. A centrifugal governor controls the action of the pointer in this instrument and in conjunction with the indicating mechanism is an odometer for registering the mileage covered.



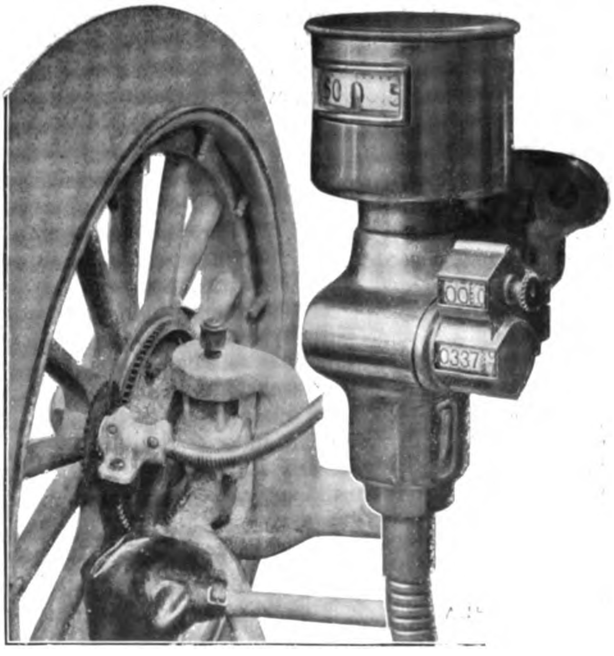
THE A.C.G.B.I. SPEEDOMETER TRIALS.—Views of the Gratze Speed Indicator and its drive. The flexible shaft causes a small iron armature to revolve between the poles of a permanent magnet and, acting upon a copper drum to which is attached the pointer, rotates it out of its normal zero position.

mechanism, and, with the exception of the Vulcan, which stands apart, some form of spur-wheel gearing has been employed. Our illustrations show such differences as exist between model and model, but, although a bevel gear is used by the Cowey, they are all, it will be noticed, virtually alike. The Vulcan, which is the only purely electrical device, has a tiny magneto driven by an elastic belt from a pulley attached to the front wheel. On the dashboard is a voltmeter, calibrated in miles per hour, which registers the voltage generated and so indicates the speed of the car.

Both the Gratze and the Warner instruments are magnetic; the former has already been described by us both in its original and latest forms, while the latter is at present under test preparatory to our impending article. Both work on the same principle, although the details of the arrangement differ considerably, as does the general appearance of the two devices. Their action depends on the dragging effect produced by a revolving magnet suitably arranged in the proximity of a pivoted copper ring or disc. As the magnet revolves, the disc, which is held by a fine spring, tends to follow it, thus pulling against the spring until the two effects neutralize one another, and the disc assumes a position of equilibrium. A pointer is, of course, attached to the copper member, and thus the speed of the car can be conveniently indicated. The Jones indicator is a simple mechanical instrument and operates on the ordinary centrifugal governor principle. The Cowey is also mechanical, but instead of employing a centrifugal governor it has an inertia governor in the form of a balanced wheel which receives impulses on its periphery from a reciprocating lever which is driven by the car. The faster the impulses, the more is the wheel thrown permanently out of balance, and being inter-



THE A.C.G.B.I. SPEEDOMETER TRIALS.—View of the Cowey Indicator with the bevel-wheel gear which drives it. This device acts on the principle of inertia, the drive being caused to transmit a series of impulses to the periphery of a balanced wheel. The faster these blows occur the more is the permanent deflection of the wheel to which the pointer is connected.



THE A.C.G.B.I. SPEEDOMETER TRIALS.—Views of the Warner Indicator and its driving mechanism. A small rotating magnet is contained in the instrument case and the moving dial is controlled by the torque induced by the magnetism acting in opposition to a fine spring which brings the reading back to zero when the car stops.

connected with a pointer, it is thus able to denote the speed of the car on a dial.

The Daily Record.

The following is a report that has been issued by the club giving the results of the runs made the first week:—

Thursday, March 1st, saw the first road run of these trials, when the three cars fitted, two of them with standard Collier tyres, and the third with an experimental beaded-edge tyre entered by the Collier Tyre Company, made the journey to Northleach and back *viâ* High Wycombe and Oxford. There was promise of rain when the start was made at 8 a.m., but nothing much came of it. The roads were, however, for the most part wet, and in places rather greasy. Parsons non-skids were therefore put on the 28-h.p. Daimler and the 20-h.p. Dennis, the 20-h.p. Rolls-Royce running without them.

At the foot of Dashwood Hill a halt was made to enable photographs to be taken of the cars. The climb, of course presented no difficulties, though the weight of the Daimler, with 5 passengers, is over two tons, and the journey was made without interruptions to Northleach and back to Witney, where the cars halted for luncheon.

The afternoon was also only remarkable for the way everything ran. There were no tyre troubles, the Dennis car, which is under observation, was unlucky to lose its "non-stop" record for the day, owing to a choked petrol filter; the Vulcan Speedometer had to be disconnected owing to a weak bracket; and the Metallic Mirror's tail light refused to burn owing to deficient air supply.

On Friday, the run was to Dunchurch and back, and this was marked by no untoward incidents to the various entries; tyres, lamps, speedometers and car all did their work correctly, with the exception of the Worsnop tail-light, which went out owing to vibration, and one of the Worsnop headlights, which got its feed-pipe choked in some way. On Saturday, the road was to Peterborough, when again tyres, car, speedometers and lamps came through successfully, with the exception that the Warner speedometer driving-gear required adjustment on the road, and one of the Worsnop headlights got choked again. The distance covered up to Saturday night was 495½ miles.

The Pradeau Spring Wheel.

ANOTHER resilient wheel has now come to the front, and is to make its *début* by a 4,000-mile trial on a Fiat car under the auspices of the club. At present we are unable to give any illustrated description, but we gather from the information provided that the wheel operates on the simple radial spring principle, the springs being accommodated in the extremities of the spokes. Lateral stability is apparently secured by the use of double rims, and the drive is evidently transmitted through hinged plungers—attached to the outer rim—which form the connecting links between the inner and outer rims, as well as being the direct means of operating upon the springs which are inside the spokes.

Gothenburg-Stockholm.

IN THE AUTOMOTOR JOURNAL for February 24th it was mentioned that E. Salmson, on a 24-h.p. Fiat, had covered the distance of 500 kiloms., in this trial, in a record time. The final awards are now announced by the A.C. of Sweden as follows:—

1. E. Salmson, 24-h.p. Fiat, 26h. 18m.
2. H. Dahn, 12-h.p. Darracq, 38h. 42m.
3. Bagge, 24-h.p. Star; 4. Petersen, 7-h.p. Oldsmobile.

An Open Hill Climb.

THE Southern Motor Club are organising an open event, which will take the form of a hill-climbing contest, to be held on April 7th.

A Tyre-Fitting Record.

2 MINS. 30⅖ secs. is a record for tyre-fitting, and has been accomplished, we learn, by the winner of the Tyre-Fitting Competition, held by the Continental Tyre Company at the recent Berlin Motor Exhibition. During this time a Continental motor cover and tube were taken off and replaced. The previous record was 5 mins. 45⅖ secs., made by the winner of the competition held by this Company at the Olympia Motor Show, 1904.

MOTOR BOATING.

Our Canals and Waterways.

A ROYAL COMMISSION has been appointed to inquire into the canals and inland navigations of the United Kingdom—as foreshadowed by the Prime Minister's programme in his Albert Hall speech.

The Commission will report on the following points:—

1. Their present condition and financial position.
2. The causes which have operated to prevent the carrying out of improvements by private enterprise, and whether such causes are removable by legislation.
3. Facilities, improvements, and extensions desirable in order to complete a system of through communication by water between centres of commercial, industrial, or agricultural importance, and between such centres and the sea.
4. The prospect of benefit to the trade of the country compatible with a reasonable return on the probable cost.
5. The expediency of canals being made or acquired by public bodies or trusts, and the methods by which funds for the purpose could be obtained and secured, and what should be the system of control and management of such bodies or trusts.

The following are the Royal Commissioners:—

Lord Shuttleworth, chairman, Lord Kenyon, Lord Brassey, K.C.B., Lord Farrer, Sir John Dorington, Bart., Sir John Brunner, Bart., M.P., Sir Francis Hopwood, K.C.B., C.M.G., Permanent Secretary of the Board of Trade, Messrs. W. J. Crossley, M.P., Russell Rea, M.P., J. F. Remnant, M.P., P. Snowden, M.P., Henry Vivian, M.P., L. A. Waldron, M.P., R. C. H. Davison, C.E., J. P. Griffith, C.E., J. C. Inglis, C.E., H. F. Killick, John Wilson, and Dr. A. J. Herbertson.

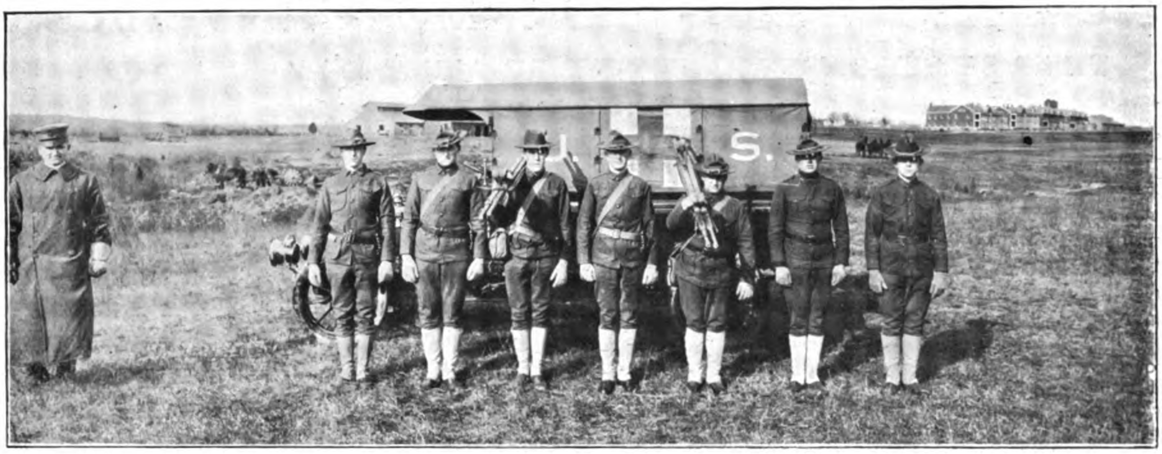
Mr. W. B. Duffield, M.A., barrister-at-law, will act as secretary.

Monaco Meeting.

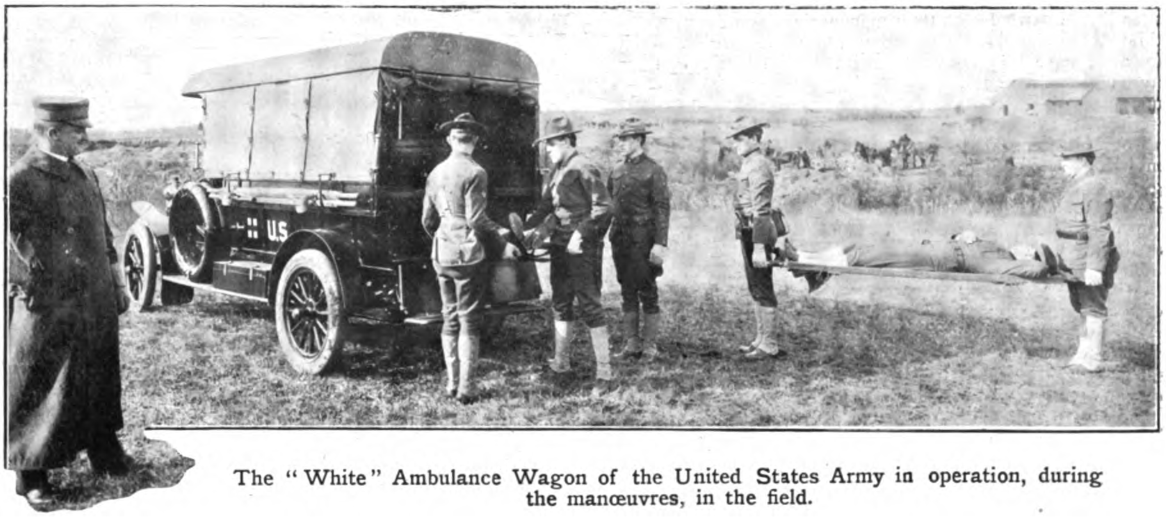
NINETY-FOUR boats—31 racers and 63 cruisers—have been entered to take part in this year's Monaco Motor Boat Meeting, April 1–15. These comprise boats of the following nationalities:—France 63, Italy 12, Great Britain 7, Switzerland 7, Germany 5. Of the British boats five are racers, viz.:—Mr. S. F. Edge's Yarrow-Napier, Mr. Mawdsley Brooke's Brooke I., Mr. J. E. Hutton's Hutton II., Mr. A. S. Cunliffe's Hutton-Saunders, and Mr. Lionel de Rothschild's Siola. British sport is represented in the cruiser class by our old friend, Takumono, owned by Mr. Miall Green, and the Daimler boat, Quicksilver, entered by Mr. J. M. Gorham. The French, German, and Italian entries include all the fastest craft known, built by each respective country.

Motor Fishing Boats.

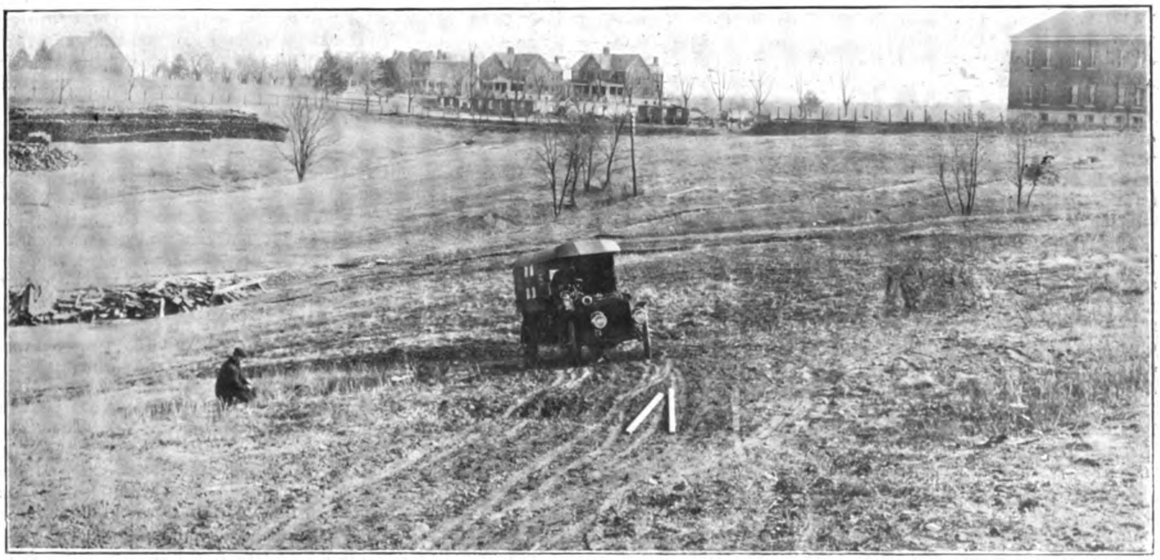
IN order to encourage the development of motors suitable for fishing boats, the French Yacht Club have offered a prize of 10,000 francs for a competition for fishing boats of the type used on the French coasts, in which an internal combustion motor is installed as an auxiliary. The contest is to take place at St. Malo, during the regatta, on August 25th to 28th.



THE MOTOR AMBULANCE IN THE UNITED STATES ARMY.—We recently gave a picture of a motor ambulance supplied by the White Steam Car Company to the United States Army. We are now enabled to supplement this by some other interesting photographs of the vehicle actually in operation. In the above picture, the squad in charge of the White ambulance is seen.



The "White" Ambulance Wagon of the United States Army in operation, during the manœuvres, in the field.



Testing the "White" Ambulance Wagon for hill-climbing by the United States Army officials, at Fort Mery, Virginia.

PNEUMATIC TYRES FOR MOTOR VEHICLES.

THEIR SELECTION, MANAGEMENT, REPAIR, AND MANUFACTURE.

By COLIN R. CROMBIE.

In this article, which is based upon a paper read recently before the Scottish Automobile Club (Eastern Section) at Edinburgh, Mr. Crombie deals with this very important subject in a manner which cannot but be of the greatest interest to all owners of cars, whether they are ardent motorists who drive their own vehicles or not. His acquaintance with the construction and management of tyres is essentially of a highly practical nature, and therefore his opinions will be read with great interest. His concluding description of tyre manufacture will also be welcomed, since it throws a particularly clear light on many vital points that are only partly understood by most motorists. Mr. Crombie, who is connected with the Victoria Rubber Company, Ltd., of Edinburgh, has had many years' experience in the rubber trade, and is consequently able to speak with authority as a manufacturer and an expert.

The question of the pneumatic tyre is always with us, and constantly affects our pockets—not infrequently our tempers also. The principle of the pneumatic tyre is a cover, to hold inside it compressed air, in what may be called a fluid state. This combination of rubber and compressed air has given such remarkable results that, where high speeds are required, the pneumatic tyre holds undisputed sway, and will, no doubt, continue to do so for many years to come. Nevertheless, it has its weak points, and certainly demands more careful treatment than any other form of tyre. Most of us know what we want, but there is no reasonable likelihood of our getting an absolutely perfect tyre, at all events, at present. Year by year great improvements are, however, being made in pneumatic tyres, and a little knowledge of their management and construction will, I think, often help some motorists out of difficulties, which would not arise were they conversant with certain details of their manufacture and maintenance.

My endeavour will be to try, as far as lies in my power, to explain the nature, capabilities, and construction of the pneumatic tyre, not so much from the tyre manufacturer's point of view, as in the light of the knowledge I have gained from my two years' experience of repairing covers and tubes, and also my twelve years' general experience in the rubber trade. If, in doing so, I can succeed to some little extent in smoothing the path of the motorist, the object of my remarks will have been accomplished.

Size and Life of Tyres.

Assuming that the motorist has selected a set of tyres of good repute, it rests with him to treat them with due consideration. No part of the car will repay attention so well as the tyres, and many a wearisome wait by the roadside can be avoided by getting the right tyres, and using them in the right way. The motorist will be well advised not to under-tyre a car. It is probable that a set of tyres costing, say, 50 per cent. more than the standard size of tyre supplied by the car manufacturer, will last twice as long. It is of great importance that the tyres should be of ample size and general strength, to support the required weight at high speed. Small light tyres spell frequent punctures and trouble, not to mention short life. Some motorists prefer to have light tyres on their front wheels, and heavy tyres, with square treads, on the back wheels. One disadvantage of this method of procedure is, that the convenience of interchangeability is lost, as square treads on the front wheels make steering considerably harder.

What they can, and can NOT Stand.

It must always be borne in mind that the tyres have very arduous and important work to perform, that they are more subject to injury and accident than any other portion of the car, and that they are, in fact, the protectors of the other parts of the car. They have to take the movement from the engine and carry out the vital act of propulsion. It should be remembered that the motion is given to the car by the friction of the rear tyres on the road. They must encounter every class of service, drive through dust that gives no grip, and wallow in mud till they find a solid bearing surface. The careless driver slews them about violently, drags them round corners in an excruciating way, and ever and again, to air his cleverness, he will apply his brakes so hard that the wheels lock and drag the tyres along the ground, doing immense damage to the covers. The same man will drive with his tyres imperfectly inflated, and so allow them to be rolled about most destructively on the rims. He will charge through patches of sharp stones, never taking the trouble to overhaul his tyres and mend those small cuts and gashes which allow the water to penetrate the tyre and so rot the canvas. This rotting of the canvas, which is a source of considerable anxiety to motorists, may, in most cases, be avoided if the holes are plugged in time. The canvas is more or less absorbent, and contains air. When a gash or puncture occurs in wet weather, the water enters at the holes, and by means of the capillary attraction of the canvas from within, and pressure from without, is gradually sucked and forced along between the fibres, carrying with it fine dust, mud, and grit, which disintegrate the layers of rubber and canvas, gradually sapping the strength of the cover until it finally bursts.

Correct Inflation Pressure.

The inflation of tyres to the proper pressure is a matter of great importance, and the neglect of this is a frequent source of damage. A large percentage of tyres sent in for repair show very evident signs of having been ridden under insufficient pressure. The following figures, compiled by one of the leading tyre manufacturers, give what appears to be a fair guide in the matter of pressure for various classes of tyres :—

	Front Tyre.	Back Tyre.
	lbs.	lbs.
2½ in. or 65 mm. to carry 450 lbs. per wheel	65	70
3 in. ,, 80 mm. ,, 500 lbs. ,,	70	75
3¼ in. ,, 85 mm. ,, 600 lbs. ,,	70	80
3½ in. ,, 90 mm. ,, 700 lbs. ,,	70	80
4 in. ,, 100 mm. ,, 1000 lbs. ,,	75	80
4¼ in. ,, 105 mm. ,, 1050 lbs. ,,	75	85
5 in. ,, 12c mm. ,, 1300 lbs. ,,	90	95
5½ in. ,, 135 mm. ,, 1400 lbs. ,,	95	100

The above figures refer, of course, to new tyres. Old tyres, or such as have been repaired, should obviously not be subjected to quite the same amount of pressure, and a little discretion should be exercised in inflating them. It will generally be found advisable to reduce the above pressure by a few lbs. in the case of such tyres.

Frequent Testing Recommended.

All tyres should be inflated with a pump to which a pressure gauge is attached, and ought to be tested at least every two days to see that the air is under its right compression. There is always a slight leak at the valve unless the fittings are perfect. It is a good thing occasionally to test the valve itself with a tumbler of water. If there be insufficient air, or none at all, in the tyre, then the cover gets jammed between the rim and the road, and if used in this state for any length of time becomes totally destroyed. The damage caused in this way consists in the cutting of the tyre at the bead, and also in the separation of the plies of canvas from one another. When this happens the tyre is beyond repair.

Outer Covers Damaged by Damp and by Strong Light.

Strong light and changes of temperature are two enemies of rubber. Light more particularly affects it and destroys its elasticity, which is its most important property. By too strong a light I mean chiefly the rays of the sun. On the surface of tyres which have been exposed to constant sunlight for any length of time, there appear small surface cracks, which gradually extend until the tyre is covered with them and becomes quite hard. The rubber on the tread will then grind away and it becomes necessary to have the tyre retreaded. To obviate this, rubber tyres should be stored in a dark place, but the main point is to prevent the direct rays of the sun from reaching them. Neither should the store room be damp, as this will rot the canvas. Covers and tubes should be wrapped in canvas, and put away in a dark store room, free from damp and of an even temperature. Though perfectly proof against water, rubber is easily affected by oils and acids, and if exposed to their action for any length of time, soon becomes decomposed. To avoid this risk of damage, always wipe off any oil or acid as soon as it is observed.

Replacing Inner Tubes.

Considering next the care of inner tubes, there are two kind of motor wheels at present in use, those with metal spokes and those with wooden ones. Special care is required in putting tyres on the former, as the spoke heads always project more or less through the rim, and are apt to damage the tube. To avoid this, a strip of canvas should be carefully cemented round the inner circles of the rim. It frequently happens that this strip is shifted to one side, thus allowing the projecting spoke heads to rub against and injure the tube. It often happens, too, that the tube is nipped between the badly fitting edge of the cover and the rim. The source of such accidents is hard to trace, and is generally attributed to a nail which can't be found. There are two different ways of nipping, either between the edge of the cover and the rim or between the edge of the cover and the security bolts. When the car is in motion, the tube in both cases is thus subjected to friction, which it cannot withstand for any length of time, and bursts with a loud report. The greatest care should be taken to place the tyre properly in the rim.

To avoid "Nipping."

The best way to ascertain whether the inner tube, after adjusting and before inflating, is in its proper place or not, is to push the security bolts back again through the rim and pull them outwards once more. If this can be done easily, it shows that the tube is in its right place; if, on the contrary, there is some resistance, it is a sign that something is wrong. The fault can easily be remedied by lifting slightly the edge of the cover and readjusting the tube. If these precautions are neglected, one runs the risk of having an accident on the road, and it is better to spend a little time at the start and see that everything is right. It not infrequently happens that the tube is nipped by the lever. When taking off or putting on a cover, special care should be taken not to push the lever too far underneath, as otherwise the tube may get under the lever and get nipped between it and the iron rims.

Faulty Valves.

In a great number of cases, the tube is found to be leaking in consequence of the valve being either faulty or improperly adjusted. The valve should be occasionally tested, and this is simply done by holding a glass of water up to it. If air is found to be passing some of the parts will require looking to.

(To be continued.)

* * * *

THE PROBLEM OF LONDON TRAFFIC.

THE following are a few of the more interesting and suggestive points and passages from the admirably thought out, carefully considered, and pithy paper read by Capt. G. S. C. Swinton, L.C.C., before the Society of Arts last week, to which we refer editorially in another column:—

London is suffering the penalty of over-popularity; how are we to cope with it?

We regretfully put on one side the oldest thoroughfare of all, the waters of the Thames, historic, free and open, unhampered by cross traffic, never in need of costly relaying. If the barrage scheme came to anything, if the 3,000 odd acres of river surface which traverses London from end to end, our greatest lung, almost comparable in size to all our parks and open spaces rolled into one, were converted from what it really is, a sheltered arm of the sea, into an inland lake, then it might be possible to use its waters for everyday trading purposes, even to run a continuous passenger service which could compete in speed and price with the more up-to-date methods on land.

Who, even a generation ago, would have thought of the incalculable value to us of our stratum of blue clay, or could have imagined that, in 1906, we should be told that the Underground Electric Railways Company was completing arrangements for dealing with nearly 600,000,000 of passengers annually over 100 miles of lines?

Private enterprise has sunk 16,000,000 sovereigns in order that we may move and move fast.

What are the requirements of the ideal thoroughfare? A good surface, the wider the better, easy gradients, no obstruction and therefore safety for all parties. It is a rare combination.

I have referred to the "over and under" method of dealing with cross traffic, and fortunately there is no longer any necessity to argue about the method being ideal. In teaching the lesson we have all of us learnt its difficulties. Mr. Fitzmaurice, the engineer of the London County Council, has laid it down that in his opinion an 18 ft. headway, a 2 ft. 6 in. superstructure, and a 1 in 30 gradient are all essential. These figures, on a dead-level road, make the approaches 200 yards long at either end.

After all is said and done, when we have cut London about to our hearts' content, what are the vehicles which are going to traverse our improved streets? On one point we have made up our minds. A revolution has taken place, and we have altered our standards of speed. The walking and trotting paces of a horse—four miles an hour and eight to twelve miles an hour—will suffice us no longer. To turn our attention first to public conveyances, we see that the horse omnibus is going the way of the horse tramway. What is to take its place? Will the travelling public of the future elect to be carried smoothly along the middle of certain roads on a fixed line of rails, or will it prefer a slightly rougher but more mobile service, which will take it in any direction and pick it up off the pavement at any point? Will the vehicles employed be dependent for their motive power on more definite street connection, or will they wander about the town relying each on its individual engine? At the moment it is impossible to say. It is, or it certainly should be, a question of which system gives the best all-round value to the community, which system will move fastest, cause least obstruction, and be the cheapest.

The motor omnibuses (I think it well to mention that I am not financially interested in them to the extent of one penny) are doing extraordinarily well, and earning large rewards; but it is early days for any certain estimate to be formed of their lasting, and so of their paying, capabilities. They are fast, and when well driven they minimise congestion. When in bad repair or badly driven they are noisy. The effect on the road surface, more especially of their great weight on pipes and connections beneath the surface, has been seriously questioned; but it is difficult to believe that the general tendency of their broad, rubber-shod wheels will not be to the advantage of all kinds of paving. We must remember that they are still in their infancy, and capable of very considerable improvement.

What, on the other hand, is the future of the street tramway? It is indisputably the most comfortable mode of progression, excellent in wide uncongested streets, but in heavy traffic it is obstructive, and quite unable to do itself justice and show its natural turn of speed. Many will say that it has arrived at its zenith, and that no improvements or cheapening can be looked for. And when we talk of cheapening, and come to the question of cost, what do we in London pay for our system? At present no one knows; but a return dealing with the expenditure on street widening and other incidental expenses along tramway routes which the Finance Committee of the County Council will shortly present, will, I think, be a revelation.

Surely all here will agree that, if the interests of general traffic are to be considered, no tramway should be permitted along any main thoroughfare unless there is to be 18 feet clear on either side. If, to get this width, for tramway purposes—I must emphasise these words—costly widenings and consequent repaving and other expenditure are required, that is tramway business, and the expense should be charged against the tramway enterprise.

Do you realise what horses cost London by the beat of their iron-shod hoofs, and the cleansing which their presence necessitates? In the City of Westminster there are 100 miles of streets, and the repaving, maintenance and cleansing, costs about £1,500 per mile annually.

When half the gentlemen of England are going into training as mechanics, the horse becomes a luxury for the rich. Fancy the advantage of no string of cabs taking up, the four-wheelers 120 sq. ft., and hansoms 90 sq. ft., in streets like Piccadilly, where a square foot of land is worth £20. For with a proper motor cab system, the stands would all be underground, a single specimen alone on the street level being replaced by lift from below the moment he was called off his stand. But the advantages to inner London of the disappearance of half its horses cannot be done justice to at this hour of the evening. Taking all motors together in the year ending December 31st, 1904, 5,023 were registered in London, including only four motor omnibuses. This, of course, being the first year, included all then running. To that number there were added last year 4,074, including 236 motor omnibuses. What will the figures be ten months hence? The disappearance of the horse would have one effect, it would add half as much again to the general speed of the town.

CORRESPONDENCE.

MOTOR 'BUS RACING.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I am glad to see your article on page 221 of your last issue, on the subject of motor 'bus racing. No doubt, on the face of it, this reprehensible practice is due to the sporting instincts of the drivers and conductors. If we only knew, books are probably made on the two events, the takings, and point to point. There may be further books made on donkey race lines—who carries fewest passengers—and maybe handicaps requiring an umpire's decision whether a corpse of a would-be passenger killed by 'bus nursing counts, if it can be proved that the corpse wished when alive to be a passenger.

A benefactor of mankind is he who can cause two blades of grass to grow where one grew before. Omnibus management, whether equine or mechanically tracted, is not run on these lines. The great principle seems to be—"Never mind about growing new blades of grass (new routes), but snatch your neighbour's blades of grass, whether full grown or only just above ground."

In vain have I written to motor 'bus companies urging upon them to start a route from near Waterloo Station, in the Waterloo or York Roads, to Sloane Street over Westminster Bridge. I am convinced there is a good motor 'bus route to be formed between Waterloo and Victoria Stations, bringing people to the House of Commons and all that neighbourhood, and to the countless offices in Westminster, and the Army and Navy Stores and to Victoria, to Sloane Street and to Harrod's Stores. In reply to these suggestions I receive platitudes about difficulties and inabilities to procure cars, &c. I have no doubt, however, that a good track could be developed on the routes suggested. At present, it seems more important to rival motor 'bus proprietors to prevent, say, "Vanguards" from carrying passengers than to earn dividends for their shareholders. This sort of thing generally leads to a clear out of those responsible when it occurs in a manufactory, trade or engineering business, and now that omnibuses are beginning to attract the clear heads of engineers into their directorate and construction, we may hope to see clearer-headed and cleaner business methods of management also adopted.

Faithfully yours,
"FOUNDER MEMBER 70."

Crankpin, London.

HISTORICAL MOTOR CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I find that Mr. Claude Johnson, from the reports of the paper read before the Society of Arts, has stated that he found the greatest difficulty in obtaining detailed information regarding the earlier cars, even from the manufacturers themselves. But Mr. Johnson, in referring to the commencing literature on the subject, would have found the earlier or pioneer petrol or petroleum vehicles clearly described, not only from the historical, but also, and chiefly, from the technical, point of view, in my paper on "Petroleum Motor Vehicles," read before the Society of Engineers, at the United Service Institution, Whitehall, in May, 1899. This paper not only describes but illustrates all the chief pioneer vehicles to that date, and up to this date Mr. Johnson could have found in this publication the required particulars. The paper describes and illustrates the first motor tricycle (Mr. Butler's); and the first motor car (my own), built in this country, and also the majority of the earlier cars and tricycles. Particulars are also given of the first automobile engine made and sold in this country, which was exhibited by me at the Stanley Show of 1894, and several of these engines were sold to French buyers, one to the Peugeot firm.

The meeting was attended by a large number, probably the majority, of engineers engaged in the industry at that time, and there was a very full discussion, which is printed with the paper. The paper was published by the Society of Engineers.

I have noticed that this paper has been frequently drawn upon by subsequent authors of papers and other publications, and generally without acknowledgment, so that I am not surprised that Mr. Johnson, not being an engineer (and the paper dealing chiefly with the technical side of the subject), was apparently not aware of its existence until I called his attention to it.

Yours faithfully,
I. D. ROOTS.

March 5th.

UNOFFICIAL COMPETITIONS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—With reference to the challenge issued by Messrs. Mors, Limited, immediately after last year's Tourist Trophy Race, to run a reliability trial against the winning Arrol-Johnston car, we asked permission from the Automobile Club of Great Britain and Ireland to accept this challenge, but the Competitions Committee of the Club have refused their sanction.

Yours truly,
For THE NEW ARROL-JOHNSTON CAR COMPANY, LTD.,
W. S. MACLARG, Secretary.

MIS-USE OF THE FOOT BRAKE.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—We agree with Mr. Wellington that it is most important the foot brake should be used with great care, as every other portion of the mechanism of a car should be used, but I cannot agree that the purchase on the back brake is one-third greater as a rule than the purchase on the foot brake, insomuch as the foot brake works through a reducing gear of an average of about 3½ or 4 to 1, and, of course, increases the holding power of the foot brake in direct proportion.

The increase, of course, in a live axle car is obtained in the bevels, and in the chain-driven cars in the sprocket-wheels.

Yours faithfully,
J. W. BROOKE AND COMPANY, LIMITED,
March 2nd. MAWDSLEY BROOKE.

THE FLYING PROBLEM.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In answer to Mr. J. D. Roots' letter, I was at one time of the same opinion as Mr. Roots, namely, that an aeroplane was too erratic and uncontrollable to ever become a safe and satisfactory means of aerial locomotion, but I continued my experiments with encouraging results and came to the conclusion that flying on the basis I advocate should be quite feasible.

I do not believe in placing too much reliance on models, but at the same time it must be admitted they are a guide to the solution, and if one cannot obtain satisfactory results with models, then there is little hope of success with full-size machines.

On the other hand, if it can be demonstrated that weighted models when thrown into the air, or liberated in any position from a height, on a windy day, will quickly right themselves and come gliding gently and safely to earth, then there are some grounds for believing it possible for larger machines to be equally stable in the air.

I find on throwing, or liberating in any position, several different models of my own type into the air, with or against the wind, they come down gently heading the wind. Also the moving of the weight either slightly forward or backward, to the right or to the left, has little effect. These are, in my opinion, very desirable features.

The above statements answer Mr. Roots' first and fourth objections to the aeroplane, as they prove, should the engine stop, or the machine come into a gust of wind, it would not capsize, but glide gently to the ground.

The other objections, *re* more convenient methods of starting, stopping, and the space required, &c., are matters which can be left to be overcome with the experience and knowledge gained when flying.

Yours faithfully,
A. V. ROE.

THE AUTOMOBILE ASSOCIATION AND ITS REVISED POLICY.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—For the coming season we are making important alterations and improvements in the *personnel* of the A.A. Cyclist Organisation.

To this end the men are being trained in tyre repairs—including the use of the Harvey-Frost portable vulcanizer, by favour of the proprietors of that invention. They will carry spare patching outfits, and where possible a light tow rope. Each cyclist will be well grounded in all local information as to the situation of repair shops, nearest garage, doctor, water supply, &c., in order that the corps' reputation as an important factor in the comfort and enjoyment of a week-end motor run shall be enhanced. The harmless and necessary patrol will be still harmless, but much more necessary.

It is only reasonable that with the added burden of the foregoing duties, it will not be practicable for our cyclists to render impartial help to all motorists. They will have quite enough to do to look after members of the Association; it follows, therefore, that, to borrow an expression used in theatrical circles: "On and after a given date, to be announced immediately, the Free List will be suspended."

Many motorists habitually enlist the services of our patrols without subscribing a single penny, and in a few instances they have actually written to the committee criticising our methods and offering superfluous and valueless suggestions. Non-subscribers must, therefore, not be annoyed when our patrols politely decline to assist them, because the refusal is made in obedience to instructions. It may be said, without giving offence, that for this decision the motoring dead-head has only himself to blame.

I beg the kindly hospitality of your columns for these few important particulars, and my committee wish to assure the motoring community that the new departures in no way affect the declared policy of the Association, inasmuch as the necessary restraint will still be exercised upon all and sundry offenders in respect of dangerous or inconsiderate speeding. Nor in this, our own programme of practical road supervision, do we encroach upon the work of any other and older organisation. The Automobile Association patrol will be an adjunct to and not a substitute for the local repair shops, and in addition to the experiments now being made with a device by which members of the Association will be made known to its servants, and about which a confidential circular will be issued to each member in due course, we are not forgetting to arrange that firms in the motor car industry shall enjoy the benefits of our work as freely as they are assisting us.

I am, sir,
Your obedient servant,
STENSON COOKE, Secretary,
The Automobile Association.

18, Fleet Street, E.C., March 6th.

FOUR-CYLINDER AND SIX-CYLINDER CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I have read with interest the letter signed by Mr. J. Lambert in your last issue. If Mr. Lambert will carefully read my letter of February 19th, he will find that I did not express any opinion; I suggested then, and I suggest now, that it would be interesting to obtain the opinion of Herr Maybach, and other constructors, on 6-cylinder engines, whose opinions would be valued far more than those of Mr. Lambert or the writer of this letter.

Yours faithfully,
March 6th. W. M. LETTS.

BRITISH OUTPUT.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I read with very much regret a letter by Mr. J. D. Siddeley in your last issue which appears to me to be written for the purpose of trying to prove that all British motor car manufacturers have deliberately made false statements as to their output except Mr. J. D. Siddeley himself.

The figures which I gave, namely, £484,000, as approximately the British output for the month of January, were obtained by personally writing to the principal firms in Great Britain, and with the exception of two or three firms, I received absolutely clear figures as to the number of cars manufactured in January, and the value.

Mr. Siddeley certainly did not give me the value or the number of his cars, but he told me the amount of his "weekly wages bill," as he says in his letter.

As I wished my figures to be exceedingly accurate, and not to err on the side of being too high, I had, curiously enough in Mr. Siddeley's case, taken the published figures of his company's output which have appeared week by week in the motor paper advertisements of his own firm last year, and understanding that since Mr. Austin left that the output of Mr. Siddeley's firm for motor cars has been somewhat reduced, I halved the value of cars that they were then selling, and the turnover I have shown is far below that which the number of men Mr. Siddeley says are employed could reasonably be expected to turn out.

It was exceedingly kind of Mr. Siddeley to be so frank with me in regard to the number of workmen his firm are employing, and the wages they are paying, and when he wrote me this letter I can only assume by the letter he has now written to the paper that he had hoped that I should be misled by the large figures sent, and imagined that I would think these men were fully employed making nothing but motor cars. If, however, Mr. Siddeley thinks that I have over-estimated the output of his factory by taking it at half what it was eighteen months ago, then undoubtedly my figures are wrong. Perhaps Mr. Siddeley would say how much more his firm's business has depreciated since he took charge, and I will reduce my figures accordingly.

Yours truly,
March 2nd. S. F. EDGE.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Mr. Edge wrote to us in a similar way that he appears to have written Mr. Siddeley, and was supplied by us with every possible information to enable him to formulate statistics which might prove, and in our opinion have proved, of inestimable value to the British motor industry.

We presume that there are other firms who have endeavoured to help Mr. Edge in a similar manner, and thus enabled him to get figures together sufficient to justify his statements. Probably if everyone had been as helpful as Mr. Siddeley was, the statement would never had been made at all, to the disadvantage of the British industry.

Yours faithfully,
J. W. BROOKE AND COMPANY, LIMITED,
MAWDSLEY BROOKE.

March 2nd.

THE QUESTION OF GUARANTEE.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Mr. S. F. Edge, with his usual ability for making himself prominent, has been suggesting that the British motor car trade, for the purposes of combating the foreign industry, should give a three years' guarantee, and suggests that his brother British manufacturers should do the same.

In view of the difference in price charged by Mr. Edge for his goods, and those charged by other of his British and foreign competitors, I would suggest that the proposition is a bad one coming from him; and I would equally suggest that before he makes such propositions, he should first consider the advisability (for the benefit of the British industry) of bringing his prices down to the level of other makers and in proportion thereto.

To make my letter as short as possible, I give you herewith under a list of cars with their respective bores and strokes, their cubical inch contents, their brake horse-power calculated at 10 cubic inch for one b.h.p. (which is a good maximum efficiency), the price of each vehicle, and the price per b.h.p. :—

40-h.p. Napier, 4 × 4 (6 cylinders) = 300 cubic inch contents or 30 b.h.p. Price £1,250 = £41·50 per h.p.
30-h.p. Maudslay, 4½ × 4 (6 cylinders) = 380 cubic inch contents or 38 b.h.p. Price £825 = £22·75 per b.h.p.
24-h.p. Fiat, 125 × 150 (4 cylinders) = 450 cubic inch contents or 45 b.h.p. Price £720 = £16 per b.h.p.
32-h.p. Siddeley, 5¼ × 5 (4 cylinders) = 430 cubic inch contents or 43 b.h.p. Price £775 = £18 per b.h.p.
35-h.p. Daimler, 134 × 150 (4 cylinders) = 520 cubic inch contents or 52 b.h.p. Price £990 = £19 per b.h.p.
24-h.p. Itala, 130 × 140 (4 cylinders) = 460 cubic inch contents or 46 b.h.p. Price £850 = £18·40 b.h.p.
40-h.p. De Dietrich, 130 × 160 (4 cylinders) = 510 cubic inch contents or 51 b.h.p. Price £1,100 = £21·50 per b.h.p.

In comparison with each and every of the makers above quoted Mr. Edge's car works out as follows :—

In comparison with the Maudslay, he should charge £825 for his chassis, or in comparison he is £570 too dear.

In comparison with the Fiat, he should charge £480 for his chassis, or he is £770 too dear.

In comparison with the Siddeley, he should charge £540, or he is £710 too dear.

In comparison with the Daimler, he should charge £770, or he is £680 too dear.

In comparison with the Itala, he should charge £550, or he is £700 too dear.

In comparison with the De Dietrich, he should charge £645, or he is £700 too dear.

Further comment is needless. Mr. Edge can give three, four and five years' guarantee and even then he is dearer than his competitors, and I repeat it does not come well from him to suggest that his competitors who are so much cheaper should give such lengthy guarantees.

I have every pleasure in enclosing you a copy of this letter to each of the firms whose names I have taken the liberty of mentioning, and trust that you will find space for my letter in defence of both British and foreign manufacturers.

I am,
Faithfully yours,
March 2nd. D. M. WEIGEL.

CLUBS AND ASSOCIATIONS.

A.C.G.B.I.

FOLLOWING the house dinner, a smoking concert was announced to be held at the Automobile Club on Thursday evening of this week, at 9 o'clock, and amongst those who were down to take part in the programme were: Mr. Paul Rubens, Mr. L. Grossmith, Mr. Maurice Harvey, Mr. John Bromley, Mr. Arthur Helmore, Mr. Charles Pond, Mr. Fred Russell, Mr. Louis Roche, Mr. Charles Collette, Mr. Walter Walters.

British Motor Boat Club.

THE annual general meeting of this club was held at the headquarters, Craven Hotel, Charing Cross, on Tuesday last week.

The officers for the ensuing year were appointed as follows:—*Commodore*, Admiral Sir William Kennedy, K.C.B.; *Vice-Commodore*, the Marquis of Ailsa; *Rear-Commodore*, Mr. W. Miall Green. The committee consists of the following gentlemen: Viscount Royston, Lieut. W. Windham, R.N., Lieut. H. G. Vereker, R.N., Messrs. R. Haden Tebb, R. Denys Dundas, W. Lawrance, Ernest Owers, L. Stroud, A. G. Fentiman, F. Simms, Seaton Edge, Charles Jarrott, Mawdsley Brooke, L. Miles, A. Kenealy, C. Cordingley, G. de Holden Stone, E. Kenealy, A. Harden, H. T. Arnott, G. Neill, J. S. Holmes, F. C. Blake, N. B. Kenealy, F. B. East, Oswald B. Colls, A. Lee Guiness.

It was decided to form branches and affiliated branches in various parts of the United Kingdom.

The statement of accounts showed the club to be in a healthy condition.

On the 14th inst., a paper, written by Mr. G. de Holden Stone on "The Requirements of Marine Motors in Design and Construction," will be read at the head-quarters of the club, following the usual house dinner.

East Surrey A.C.

MAJOR KINGSLEY O. FOSTER, J.P., the President of the Club, occupied the chair at the general meeting of this club, which took place last week, when a very satisfactory showing was made in the accounts for the year, there being a balance of more than double that of the previous corresponding period. The chief business, besides the passing of the report, was the election of officers, which resulted in Capt. Rawson being selected as president for the ensuing year, and the other officers as follows: *Vice-Presidents*—Sir A. Rendel, Sir G. Livesey, C.E., Major Kingsley O. Foster, J.P., Mr. H. Bell, Mr. H. M. Corsellis, and Mr. J. B. Purchase. *Committee*—Messrs. G. H. Bowden, N. Colman, W. F. Garside, H. Hughes, A. Gunning Keen, H. Rosling, J. Underhill, C. H. Whittington, and J. Whittington. *Hon. Secretary and Treasurer*—Mr. D. J. Barry.

Marine Motor Association.

A MEETING of the council of the Marine Motor Association was held March 1st, among those present being Messrs. Linton Hope, chairman, Alfred Harden, W. Miall Green, A. Vaughan Williams, Seaton Edge, and J. A. Smith, assistant secretary.

The principal business before the meeting was the settling of the agenda for the spring general meeting, the date of which has been fixed for the 22nd inst. The new rule requiring all motor launches to be fitted with exhaust silencers came up for discussion, and the whole question will be reconsidered at the general meeting.

It was a matter for great regret that Major Lloyd has been compelled to retire from the presidency of the Association on account of ill-health. Major Lloyd has held the office of president for upwards of two years, and has been an indefatigable worker in the interests of the Association.

The new rule books of the M.M.A. are now ready, and copies may be obtained from the assistant secretary, Mr. James A. Smith, 47, Leadenhall Street, E.C., at a charge to non-members of 6*d*. per copy.

Motor Union.

AT the last meeting of the general committee of the Motor Union, the following were elected to life membership:—Messrs. Charles H. Sample, Corbridge-on-Tyne; Norman Barker, Bowdon, Cheshire; Edward T. King, Pulborough, Sussex; R. Jackson, M.B., St. Helens; W. Marden, Surbiton; James Cooper, Scarborough; John Kennedy, J.P., D.L., London.

Mr. Arthur Du Cros, on behalf of the Dunlop Pneumatic Tyre Company, Limited, has forwarded a cheque for fifty guineas as a contribution to the Legislative Defence Fund of the Motor Union.

Motor Yacht Club.

THE first annual general meeting of the club (late Marine Motor Club) was held at 119, Piccadilly last week, Sir Boverton Redwood, the Vice-Commodore, presiding. The report outlined a satisfactory state of affairs, whilst the financial statement showed a surplus on the year of over £600. In the report, the Committee explained that the club was founded by the A.C.G.B.I. in June, 1905, to take over the duties of the Marine Motor Committee, elected by that body in December, 1902, to promote the interest of motoring in the water. The membership of the club now totals to 150, and it was announced that a challenge had been received from America for the International Cup, won on September 11th last at Arcachon, by Lord Montagu, then the Hon. John Scott Montagu, M.P., with Napier II., owned by Lord Montagu and Mr. Lionel de Rothschild.

Sir Boverton Redwood congratulated the club upon the past year's work, and he thought that no club had a better chance to develop into a first-class organisation. It was now well established with a sound financial position, and the future history of the club was in the members' own hands. They had to thank the liberality and generosity of the rear commodore, Commander Mansfield Cumming, R.N., for the magnificent floating club-house in the ex-Admiralty yacht "Enchantress." In regard to this floating club-house, it was explained that a large number of state rooms were being arranged, and that there would be adequate accommodation on the yacht for about 1,000 people without overcrowding. The new club-house would be ready for occupation about May 1st next.

The report and accounts were unanimously adopted.

The Society of Motor Manufacturers and Traders.

GREAT activity prevailed last week amongst the committees of the various sections of the society. On Monday the committee of the Commercial Vehicle Section met, when the issue of the police regulations *re* motor 'buses was reported, and complete satisfaction was expressed at the result attained through the joint efforts of the makers and users, which had been conducted by the society, and a vote of thanks was passed to the delegates who had served on the deputation to the Chief Commissioner.

On Tuesday the new Tyre and Accessories Section held their first meeting, when Mr. W. G. Williams, of the Collier Tyre Company, was elected chairman. A number of matters of interest to the section was discussed, including the important matter of infringements of registered articles, in which there is now a considerable illicit trade, and a recommendation was made to the committee of management, which may result in serious proceedings being taken.

On Friday the committee of management met. A sum of ten guineas was voted to the Auto-Cycle Club towards their expenses in challenging for the International Motor Cycle Race. A deputation was received from the Importers' Protection Association, and it was resolved to call an early meeting of the committee for the purpose of defining a policy which would meet the requirements put forward by this association, and by the British Empire Motor Trades Alliance.

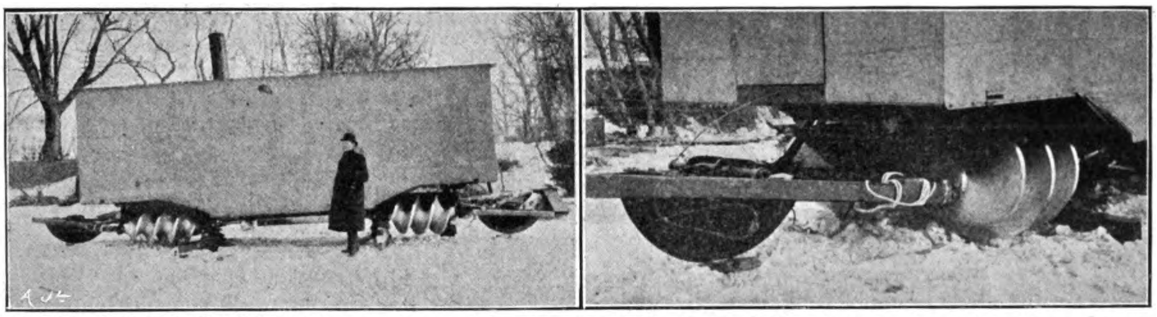
MOTOR CYCLING.

Land's End to John-o-Groats Trial.

FOURTEEN entries for the Auto Cycle Club long distance trial have, up to the present, been announced. We would remind those who contemplate entering that it is dangerous to delay, as the Committee of the Club have the right to limit entries.

Motor Bicycle Championship.

FOLLOWING the protest of the Austrian Automobile Club, to which attention has been drawn in THE AUTOMOTOR JOURNAL, in regard to the International Cup of the Moto Cycle Club of France, the French Club have now reconsidered the position, and announce that they have determined that their new motor bicycle *International* Championship shall no longer be international but shall be open to French makers only. They cannot, however, see their way to alter the date to one subsequent to that of the International Cup. The French motor bicycle events will therefore take place, as already announced by us, on May 27th and June 10th, whilst the original "International Cup," in which France will only be represented by one small and unknown maker, viz., the Gillet firm, will be run, as originally fixed, in Austria, with most of its glory unfortunately shorn by the action of the French Club. The French Moto Club explain very politely that they have never had any wish to in any way detract from the International Race which they originally created, but there are those in the motor cycle world who will remain of the opinion that their expressed wishes might have been demonstrated in a different form than that adopted, viz., of creating new events in France and practically thereby ostracising the "International Cup," simply because they had the misfortune not to win it last year.



AN ICE LOCOMOTIVE.—Views of a machine by which Mr. C. E. S. Burch hopes to replace the sleigh dogs of Alaska in the transport of goods over the ice during winter time. Our photographs, which are by the "Scientific American," show the propellers which replace the wheels, and also the peculiar semi-disc rudders.

AN ICE LOCOMOTIVE.

Few systems of transport remain uncontested by the automobile, and now even the sleigh dogs of Alaska are about to feel the brunt of competition. During the winter months there is a goods transport service which is at present conducted entirely by dog haulage. Recently, however, Mr. C. E. S. Burch—who is personally interested in the transport of the district—has designed an ice locomotive, which he proposes to use instead of the dogs.

This machine is built on very original lines. It has four large spiral "propellers" in place of wheels, and each is coupled direct to a steam engine. The screws are 27 ins. diameter, the engines develop 42 h.p., the overall length of the machine is 22 ft., and its weight 4½ tons.

Steering is effected by means of semi-disc rudders, and the locomotive can, says the *Scientific American*, to which we are indebted for our facts, "be driven forwards, backward, sideways, or at any oblique angle desired, and it can even be made to spin round like a top." Nothing is said as to whether some of these latter capabilities were not found to be inherent and apt to choose their own occasion for demonstrating their presence; but the top-like propensities, at any rate, have no very obvious utility, even if quite under control.

We understand that a speed of 18 miles per hour was attained on the trial run, and that obstacles caused no appreciable interruption to its progress. One useful precaution is that the locomotive is made water-tight with a view to unexpected immersion. Propellers 6 ft. in diameter are used on the new machine, and these would doubtless be very useful in such an emergency by helping this amphibious and snake-like vehicle to regain its favourite element.

Testing the ordinary Automobile on Snowy Roads.

Under certain circumstances, however, it is possible to accomplish a good deal with the ordinary automobile on snowy roads, at any rate where tracks have been made by sledges. This is at least the experience of Lieut. de la Besse, of the Briançon Garrison, who has been carrying out a number of tests with an ordinary motor car in the French Alps. On the sleigh-tracks referred to, he finds that the adherence of the ordinary pneumatic tyre is remarkable. To all who have noticed, in countries where the sleigh is an institution in winter, how exceedingly slippery the tracks become, Lieut. de la Besse's conclusions will come as something of a surprise. In the neighbourhood of Grenoble and Briançon, Lieut. de la Besse drove a 14-h.p. machine, with ordinary pneumatic tyres, up to altitudes of 1,200 metres, on a very considerable gradient, amounting in some cases to 10 per cent., and these long stretches were ascended on the sleigh tracks without the slightest difficulty. Where fresh snow was encountered, which had not been beaten down by sledges, things were different altogether, and the automobile became unmanageable.

Another Snow Motor.

Mr. Walter Wellman, of whose intention to reach the North Pole by navigable balloon nearly everybody is aware, has adopted a method of tackling the snow and ice with an automobile, which, though less original than the entertaining machine we illustrate above, may probably give just as good results. The weight of the car is taken on runners like an ordinary sledge, and the propulsion and grip of the driving wheels is increased by arming them with spikes. We conclude that Mr. Wellman intends to use his motor sleighs principally for establishing depôts in advance along the direction he intends ultimately to take by air-ship.

The Automobile in Argentina.

It is affirmed on good authority that there are at present 1,200 automobiles in Buenos Ayres alone. High speeds are not possible owing to the character of the roads of the Republic, but at the same time some good sporting events have already been run off, whilst others are announced for the near future by the Argentine Automobile Club, in which, however, the total distances do not range much beyond 200 kilometres.

The Motor Fire Engine that did not run amok.—Last week a paragraph was published in the daily papers purporting to describe the running amok of the new motor fire engine stationed at Wapping. As usual the affair was greatly exaggerated, as not only was the fire engine uninjured, but it went on its way, attended the fire, and was soon back standing in its station, with 100 lbs. of steam in the boiler ready for an instant turn-out. What actually happened was that, on its way to a fire, it touched the corner of a fruit stall standing by the kerb, causing the stall to overturn, knocking down the proprietor. Some of the woodwork smashed a shop window, but no further damage was done. We give a photograph above of this fine machine, which, it will be remembered, is by Merryweather and Company.

The "Competitions" Committee.

THE A.C.G.B.I. "Races Committee" is, for the future, to be known under the above title.

Stanley Show, 1906.

WE learn from Mr. E. A. Lamb, the Secretary of the Stanley Show, that their Exhibition this year will be held at the Royal Agricultural Hall from November 23rd to December 1st.

Sheffield Secures the Brotherhood-Crocker Factory.

WE hear that the head-quarters of the Brotherhood-Crocker Motor Company are to be established at Sheffield, for which purpose a tract of land has already been secured at Tinsley, where, as soon as arrangements will permit, the Brotherhood car will be manufactured.

Some People Never Learn.

A MOTOR car took fire a short time ago in Kingstown, near Dublin, a leak of petrol being apparently the cause. The inhabitants seemed quite surprised to find that throwing water on it only made matters worse! It was left to the simple intelligence of policemen to finally extinguish the conflagration with wet sacks.

Cheshire Motor 'Bus Service.

A NEW service of motor omnibuses is to be run over the roads of Cheshire and Derbyshire, serving the villages not reached by electric tramways. These are to be put on the road by the Manchester and District Motor Omnibus Company, Limited, the share capital of which has this week been offered for public subscription. An experimental service was started last week, in the Manchester district, between Hale and Flixton, and 150 vehicles are mentioned as likely to be running in the service of the Company in the near future.

Casting Stones at a Motorist.

SOME small boys on the Hammersmith Road recently armed themselves with stones, and one of them took a shot at the passing motor car of Lieut. Cecil Whittaker, of the Coldstream Guards. The missile hit Lieut. Whittaker in the eye. He at once pulled up the car and chased the young rascals up an alley, where he captured the one who had discharged the missile. The boy made a subsequent appearance at West London Police Court, and was fined fifteen shillings with the alternative of ten days' hard labour. On the whole, we are satisfied with the progress displayed. Three years ago it was the cudgel of the Ripley butcher; from that to the pebble of the street urchin represents a great advance in popular favour.

The Agricultural Hall Exhibition.

ALREADY nearly 300 exhibitors have, we learn, been allotted space at the Exhibition at the Agricultural Hall, which opens on Saturday, March 24th, and will continue until the 31st. Several new 1906 cars will be shown for the first time, whilst, supplementary to the light car section, the show of heavy vehicles, including lurries, 'buses, and municipal vans, will have a wide range, affording further conclusive evidence of the growth of this branch of the industry. During the week of the Exhibition several Automobile Societies will hold meetings and conferences of considerable importance to the movement. The organisations thus associated with the Exhibition include the Motor Union, the Automobile Mutual Protection Association, the Ladies' A.C., the Motor Van and Wagon Users' Association, the Automobile Association, and the British Motor Boat Club, as well as the Municipal Surveyor and other Societies interested in matters of local government.

Sheffield Motor Show.

DURING the week the Sheffield Motor Exhibition has proved a big success, following the opening last week end by the Lord Mayor of Sheffield, Col. Hughes, C.M.G. The Exhibition, which has been run under the auspices of the Sheffield A.C., was fully representative of pleasure cars, vehicles for trade purposes, and accessories, and must have proved a considerable convenience to many who found it impossible to visit the London Show at Olympia last November.

The Lord Mayor, when opening the Exhibition, gave forth some very strong views in regard to the sport and industry. Experience, he said, had taught him that motor cars could be used without inconvenience or danger to the public if only care was exercised by those driving them. He did not consider that it mattered a bit if the speed was 30 or 40 miles an hour so long as they had a clear road and no traffic. He was convinced that the feeling against motor cars, which now seemed to be dying away, was simply due to those drivers who did not pay attention to the traffic when they were passing it. Once drivers paid regard to the nature of the traffic they were passing, he was sure there would be little further cause for reproach.

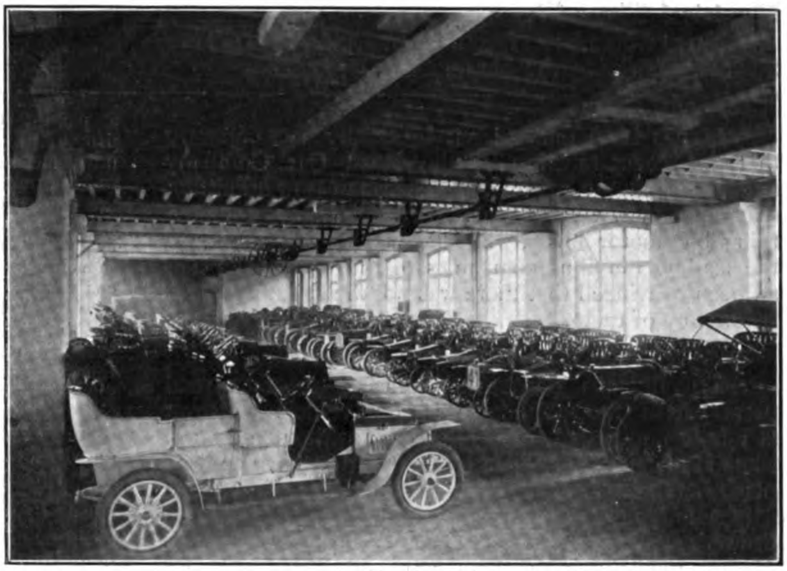

Photo by G. A. Dunn.

Recently it was announced in "The Automotor Journal" that Messrs. Darracq and Company had acquired very extensive property in Walnut Tree Walk, Kennington, for the purpose of establishing large central show rooms and a depot for the housing, repairing, and distribution of the Company's output. These premises are now coming into operation, our photograph showing one of the stock rooms "charged"; the three floors have an area of 250,000 square feet. Already eight houses and gardens adjoining the existing premises have been purchased and will be pulled down to make room for offices and showrooms. The centre of the block will form a large testing track, nearly an acre in extent, concreted and covered with a glass roof, lit by arc lamps.

Mr. E. H. Lancaster.

Innate commercial instinct combined with sound grounding in engineering, are responsible for the very rapid advance which Mr. E. H. Lancaster has made in the course of the few years in which he has been associated with the automobile industry. It seems only yesterday that he was known to most of us as the Automobile Club engineer, since which he has somehow found time to establish the Clement car upon a firm commercial footing in this country, having acted as managing director of the company exploiting this well-known make of vehicle. Mr. Lancaster has now made a further important move upwards by accepting the position of managing director of the New Enfield Autocar Company, which has just been formed for the purpose of taking over the automobile section of the business of the Enfield Cycle Company, a point which was last week mentioned in The Automotor Journal. Under his guidance the new company should, without doubt, have a big future before it, and the manufacture of this "all-British" production will be under the direct supervision of Mr. Lancaster. Mr. Lancaster is well fitted as a practical man for the post which he has now taken up, his experience in the past having been of a very varied character. Originally he was apprenticed to the Edison Continental Company, where he served for four years in their tool shop, passing from there to Messrs. Easton and Anderson, the electrical and hydraulic engineers, of Erith, with whom he remained for several years. He then came into more direct contact with motor cars at the Panhard and Levassor works, in Paris, for two years, becoming during this period the assistant of M. Cabirau, the consulting engineer to M. Camille Blanc, of Monte Carlo fame. Mr. Lancaster left M. Blanc to go to Lord Northcliffe (then Mr. Alfred Harmsworth), with whom he stayed three years, and during this period he brought over Mr. Harmsworth's 40-h.p. Mercedes to England, exhibiting it at Messrs. Cordingley's Show in 1901, where, it will be remembered, this car created a phenomenal amount of interest. It was upon leaving Mr. Harmsworth that Mr. Lancaster became the engineer to the Automobile Club, subsequently taking over, as already mentioned, the handling of the Clement car in this country. We wish Mr. Lancaster every success in his new sphere.

Mr. E. H. Lancaster.

"Motor Trade with Canada."

At the Automobile Club, on Thursday of last week, when Mr. H. Austin took the chair, the paper read by Mr. E. H. Turnbull, under the above heading, was chiefly directed towards interesting British manufacturers in the possibilities of Canada as a good market for their cars. He urged them to lose no time in establishing themselves in the Dominion, and pointed out that the preferential duty in favour of British cars ought to be a particularly strong inducement to them. In his opinion, no less than a thousand cars could be sold there this year, and ten times as many during next year. Next month automobile exhibitions are being held both in Toronto (April 7th to 14th) and in Montreal (April 21st to 28th), and Mr. Turnbull has been doing his best to persuade British firms to show their cars at both of them. Apparently the Humber Company are alone in having a Canadian agency at present, and they have sold no less than twenty-six cars since October last, when they opened that business.

Motor 'Buses to Help Tramways.

The promised motor omnibus service at Bath for the hilly Lansdown district, Widcombe and Bathampton, has been inaugurated by the Bath Electric Tramway Company.

Municipal Motor 'Buses.

MOTOR omnibuses are to be put into service in the Sneinton district by the Nottingham Corporation.

Then, and Now!

IT has been pointed out by a daily contemporary that the recent meeting of the Road Car Company makes very funny reading, the chairman now admitting that he did not think there was any chance for anything but motor 'buses, while not such a long time ago the leading omnibus companies of the Metropolis had all been convinced that there was not the slightest future before any of them.

The Unlighted Vehicle Danger.

THE hideous dangers that arise to other road users where the attendant of any vehicle whatever is idiotic enough to drive after dark without a light of some kind, was exemplified by an occurrence which took place in December last near Itchen Abbas, when Mr. Michael Malloy ran into the back of an unlighted brewer's van and injured his horse and trap. Mr. Malloy recently brought an action at Winchester for damages, and his Honour, Judge Guy, who tried the case, made some very strong remarks indeed on the dangers of the unlighted vehicle, stating it as his view that the defendants, *i.e.*, the brewer and his men, were "guilty of the grossest possible negligence. It amouted in fact to a total and reckless disregard of danger to life which might cause endless trouble and calamity." "It was bad enough," he said, "when people ran risks which affected only their own pockets and personal danger, but when, to save a few paltry shillings, they ran risks which might inflict a lifelong injury on others, it was really past belief that such things could be done. Driving at night without proper care as to lights was a matter of common complaint, but when they saw people who ought to know better doing this sort of thing, it was a serious matter, and he would draw the attention of the borough county constables to these circumstances, and particularly to this accident." These well-founded remarks of the learned Judge should have the effect of inducing a few of the remaining County Councils who have not yet got them at once to introduce bye-laws on the subject, and his remarks also should certainly have the effect of strengthening the hands of those in Parliament who are in charge of the Universal Lighting Bill.

COMPANY DOINGS.

NEW ISSUES.

Enfield Autocar Company, Ltd.—Subscriptions are invited at par for 100,000 shares of £1 each in the Enfield Autocar Company, Ltd. The Company has been formed in particular, the prospectus states, for the purpose of purchasing, as a going concern, and of carrying on and extending the manufacture and business of the autocar department of the Enfield Cycle Company, Ltd. The vendor company has for some time past been engaged in the manufacture and sale of motor cars, and has expended very considerable sums upon the production of a first-class motor vehicle. In consequence of the greatly increased trade in the cycle department and the anticipated large development of the motor car business, the works of the vendor company are not of sufficient capacity for the efficient and proper conduct of the two businesses, and it has therefore been deemed necessary to separate them. The present issue of 100,000 shares is intended to provide a sum sufficient for the following objects:—For the purchase of the freehold works, motive power, plant, machinery, stock, drawings, patterns, &c., £31,163; for extension of buildings made since January 1st, 1906, £1,517; for additional machinery, £10,000; for estimated expenses of formation of the company, £2,500; and for working capital, £54,820. It is the intention of the vendor company to apply for 15,000 shares, and the directors and officers of the vendor company will apply for at least 8,000 shares. The directors, all successful business men, are Mr. Albert Eadie, Managing Director of the Eadie Manufacturing Company, Limited, and Director of the Enfield Cycle Company, Limited; Lord Ernest J. Seymour, Chairman of the Enfield Cycle Company, Limited, and Director of the Metropolitan Bank (of England and Wales), Limited; Mr. George H. Cartland, Director of the Enfield Cycle Company, Limited, Chairman of Directors of the Eadie Manufacturing Company, Limited; Mr. Thomas Evans, Chairman of Ecco Works, Limited, Director of the Enfield Cycle Company, Limited; Mr. Robert W. Smith, M.I.M.E., Director of the Eadie Manufacturing Company, Limited, and the Enfield Cycle Company, Limited, and Director of Ecco Works, Limited; and Mr. E. H. Lancaster (Managing Director), who has been so successful in building up the Clement Car business in Great Britain.

Manchester District Motor Omnibus Company, Ltd.—Formed with a capital of £300,000, the prospectus of this Company was issued this week, 200 shares of £1 each being offered for subscription. One feature of the company is that there are no deferred shares. The company has been formed to carry on the business of a motor omnibus company in the Manchester district, for passengers, parcels and goods. A population amounting to about 1½ millions will be served. The service will cover the districts to the west and south of Manchester, which are of a residential and industrial character, and at present without adequate means of direct intercommunication, and will connect the tramway undertakings of Manchester, Salford, Stockport, Chester, and Warrington. The number of passengers carried during the past year on the several routes of these tramway systems to which the proposed motor omnibus services will act as feeders was 43,000,000. In order to ensure early delivery of at least forty motor omnibuses,

Three Orion Omnibuses which have run 50,701 miles between August of last year and February, 1906, one having been in work 27 weeks, the next 25 weeks, and the last 13 weeks, making an average of 109 miles per day after allowing for stoppages for overhauling. These omnibuses have been run by the Victoria Omnibus Company.

contracts dated 28th February, 1906, have been made by the British Transport Syndicate (Limited), with the Wolseley Tool and Motor Company (Limited), and John I. Thornycroft and Company (Limited), for delivery of forty motor omnibuses, commencing as soon as the company is ready to accept delivery.

NEW COMPANIES REGISTERED.

British Bariquand and Marre Engine Company (Limited), 18, Leadenhall Street, E.C.—Capital, £30,000 in £1 shares (20,000 preference). Object, to acquire the sole agency for Great Britain, India, Australasia, New Zealand, South Africa from the Cape to the River Zambesi and elsewhere, of motors for automobiles and parts, &c., of the make of "Bariquand and Marre." First directors, E. L. I. Blyth, H. C. Walrond, O. F. Massingberd-Mundy, and E. Haufeurt.

Manchester District Motor Omnibus Company (Limited).—Capital, £300,000 in £1 shares. First directors, D. Boyle, J. F. Albright, R. O. Ritchie, R. G. Wrightson, and H. A. Earle.

E. Mendelssohn and Company (1906) (Limited), 1A, Lancaster Gate, London.—Capital, £150,000 in £1 shares (100,000 six per cent. cumulative preference). Object, to acquire the business carried on by E. Mendelssohn and Company, Limited, manufacturers and repairers of automobiles, motor cars, &c. First directors, W. J. Masser, Vicomte Jules de Villelume Sombreuil, L. Pierron, E. G. P. Mendelssohn Bartholdy, Count Charles de Villelume Sombreuil, and A. Ménagé.

Milano Motors (Limited), 92, Gloucester Road, S.W.—Capital, £5,000 in £1 shares. Object, to adopt an agreement with Societa Milanese di Industrie Meccaniche for acquiring the sole agency in Great Britain for the Orel light car. First directors, C. Manuel, J. A. Wild, and F. H. Baker.

Motor Jobmasters (Limited), 79 and 80, York Street, Westminster.—Capital, £100 in £1 shares.

Newmobile (Limited), 78, Hamilton House, Bishopsgate Street Without, E.C.—Capital, £1,000 in 1*s.* shares. Object, to acquire from O. Percy the business of a motor car and accessory manufacturer and dealer acquired by him from P. G. Tachi, and carried on at 29, Nemoure-Road, Acton. P. G. Tachi is first director.

Premier Motor Company (Limited), 34, Waterloo Street, Birmingham.—Capital, £5,000 in £1 shares.

Silsden Motor Omnibus Company (Limited).—Capital, £2,500 in £1 shares. First directors, J. Townend, D. McDonnell, and J. W. Shuttleworth.

The Arrol-Johnston Agency (Limited), 166, St. Vincent Street, Glasgow.—Capital, £10,000 in £1 shares. Object, to carry on the business of proprietors, &c., of motor vehicles. Scotch company.

Morgan and Co., Ltd.

At the 21st ordinary meeting of the shareholders of this Company, held last week, under the presidency of Mr. J. W. Salisbury, the Chairman of the Company, a satisfactory Balance Sheet and Report were presented, and, when dealing with the automobile side of the business, the Chairman pointed out that the Directors' policy was one of caution and prudence in handling what was a comparatively new industry, as it was impossible to know what developments would take place, and what they would have to keep pace with in the motor trade. They were, however, contemplating expending a considerable sum in building a motor factory at Leighton Buzzard, as they found it was impossible for them to execute their orders without it. They would have, of course, also to put up some machinery, all of which was absolutely necessary if they were to keep pace with the times. The shareholders agreed with, and applauded the policy of the Directors in this respect. Mr. William Urquhart, the Vice-Chairman, said that a gratifying feature of the year had been the Company's success in the motor trade it was doing, and they had also the encouraging fact that that trade was greatly increasing during the present year.

London General Omnibus Company.

Very interesting were the facts given by Sir John Pound, Bart., the Chairman of the L.G.O.C., at the Company's annual general meeting held last week, in respect to the progress of the motor side of their business. He announced that during the latter portion of the half year the Directors had definitely decided to stop buying horses and to permanently close the training depôts, the result being an immediate large reduction in their stock of horses. At the end of December last, the Company had 29 motors at work. They now had 50 running, and by the end of the year they hoped to have 300 motors employed in regular service. Within three years they anticipated completing the substitution of motors for horses on the main roads. The capital expenditure necessary for this work they estimated at about one million sterling, and for the purpose of meeting this extra outlay of capital they proposed the creation of half that sum—£500,000—in 5 per cent. preference shares, the balance of the half million being provided, they hoped, by the non-replacement of their horse and rolling stock. The chairman repudiated very strongly the announcements that the British Motor 'Bus Trust or any other company or trust had control of the market for motor omnibuses. The Company were having brought to them almost every week offers from motor manufacturers, some of whom had proved the success of their machines, and at the present time they had under offer 200 from a firm whose motors were undoubtedly successful. The Company educated their own drivers, and as far as possible they intended employing them. The cost of motors, including bodies, ranged from £700 to £900. It was impossible, the chairman said, to say what the life of a motor omnibus was at present. That had yet to be learned. Of one thing he was quite certain, that motors would be able to hold their own against electric tramways.

COMMERCIAL POINTS.

Pneumatic Tyres for Motor 'Buses.

A new pneumatic tyre for motor omnibuses is, we learn, being brought out by the Continental Tyre Company after a long series of experiments have been made with it. It is much larger than the pneumatic tyres that are ever fitted to the ordinary pleasure vehicles, being 150 mm. and 165 mm. in size. The question of tyres for motor omnibuses is of so much importance that it is much to be hoped the new "Continental" tyre will fully come up to the hopes of this enterprising firm of manufacturers.

The Motor Boat Industry.

It is encouraging to find that Messrs. Brooke have recently received three important orders as the result of the enterprise with which they have developed the motor boat side of their automobile business. One of these is for a yacht's tender for the well known steam yacht "Midnight Sun." It is being built of mahogany, and will be 30 ft. long with a 6 ft. 6 in. beam. One of the 45-h.p. Brooke marine sets is to be installed, and the boat has a guaranteed speed of 14 knots. It is intended to use the launch not only as a passenger boat itself, but for towing three other boats, each loaded with thirty passengers.

Another order is for a 45-ft. passenger launch, for use on the Cam, which is being built under Board of Trade survey; while an 18-ft. teak boat is just being sent out for delivery to the Governor of Singapore.

Convincing Tests.

Those of our readers who purchase an induction coil from United Motor Industries or purchase any other coil elsewhere, can have the coil tested before their eyes with a proper apparatus at the U.M.I. depôt in London, 45, Poland Street, so that they can see the trembler speed, the current consumption, and also the result obtained from the coil when the spark has to jump across air under compression. The company inform us they will be very pleased to assist anybody to have these tests conducted with any coils in which they are interested, and the test can be carried out while the owner of the car is watching.

Motor Omnibuses and the Tyres they Use.

The Sirdar Rubber Company informs us that the London and South-Western Railway Company's new motor omnibuses are fitted with Royal Sirdar Buffer tyres, and also the new motor omnibuses of the Great Eastern Railway Company. The managing director also writes us that there has been a misapprehension with regard to the motor omnibuses of the Star Omnibus Company. It has recently been stated in the Press that they have been fitted with three makes of tyres; this is not so. All the new motor omnibuses of the Star Omnibus Company are fitted with Royal Sirdar Buffer tyres, with the exception of two sets which have been supplied by Messrs. Connolly and Co.

Mr. A. Mosses, who has been appointed manager of the Clement Motor Company, Limited, of 3, Leicester Street, Leicester Square, has been associated with the company since its inception in England. His experience in connection with motor cars and accessories is of a wide and practical nature. His engineering apprenticeship was served in the Midlands, and for three years Mr. Mosses was liner off for Messrs. Maudslay, Sons and Field, in naval engineering work. After eighteen months at Napier's works, he became head tester for the Dunlop Company, and for eighteen months was assistant manager for the Dunlop Tyre Department. Accompanying Col. Mark Mayhew, he took part in the Paris-Madrid Motor Race, and also drove in the 4,000 miles trial.

MR. J. F. CRUNDALL, the well-known racing cyclist, has joined the selling staff of the Vacuum Oil Company, Limited, manufacturers of the high grade motor car lubricants, known as Vacuum Mobiloils.

IN our last issue we gave a couple of interesting photographs of "Rapid" motor watering carts. The sole concessionaires for Great Britain, Ireland, and the Colonies, we learn, for the manufacturers of this Italian make of vehicle, are Messrs. Straker and McConnell, Ltd., of Avonmore Road, Kensington.

THE Clement Motor Company, Limited, have just received orders from Colonel W. J. Bosworth, chairman of the Automobile Association, for an 18–28-h.p. Clement, and from His Honour Judge Emden for one of their 14–18-h.p. cars.

THE Palmer Tyre, Ltd., in order to meet the requirements of the trade in Scotland for cycle and motor tyres, have opened a depôt at 6, Royal Exchange Square, Glasgow, where all orders for Scotland will be executed. Mr. J. S. Leather, who has been appointed as manager, has been connected with the London depôt for the last six years.

Diet for Motorists.

So great is the fascination of motoring that many are tempted to stay on the road for longer periods at a time than is sometimes altogether wise. The best safeguard against fatigue under such circumstances is good, wholesome, and concentrated nourishment. There is no better form of concentrated nutriment than the various "Plasmon" preparations, and the Company, with their usual energy and initiative, are now selling at 1*s.* 6*d.* a very attractive sample box (in art metal) of various preparations into which "Plasmon" has been successfully introduced. These not only include the well-known biscuits and equally well-known chocolate and cocoa, but also a nicely bound cookery book of 64 pages, giving a vast amount of valuable information in the way of recipes, &c., for household use. The box should certainly have the effect of still further popularising "Plasmon," particularly, we hope, amongst motorists, to whose requirements it is so specially suited.

⊛ ⊛ ⊛ ⊛

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

11135. 27th May, 1905. Improvements in Ignition Devices for Internal Combustion Engines. Frederick R. Simms, Welbeck Works, Kimberley Road, Willesden Lane, Kilburn, London. This invention relates to electric ignition devices for internal combustion engines, and to that class of such devices wherein the spark is obtained by the movement of a rod relatively with the ignition-plug. The plug is screwed into the cylinder, or into a chamber in communication therewith by an ignition port, and has extending through it into the chamber a rod insulated from it by means of the usual soapstone washers. There are two figures. Fig. 1 is a sectional elevation. *a* is a chamber in communication with the cylinder of the internal combustion engine by means of the port, *b*, *c* being a flange by means of which the chamber, *a*, is screwed to the cylinder. *d* is the plug of the ignition device, and *e* is the rod which extends through the plug, *d*, from which it is insulated by the soapstone washers, *f*. *g* is the lateral extension of the chamber, *a*, the inner end, which is within the chamber, *a*, having the conical head, *i*, which is normally held in contact with the head, e^1, of the rod, *e*, by means of the spring, *j*, which is coiled round the rod, *h*, within a hollow portion, *k*, of the extension, *g*, one end of the spring, *j*, bearing against the end of the extension, *k*, and the other against a collar, *l*, keyed upon the spindle, *h*. *m* is the seat in the chamber, *a*, for the conical-head, *i*, of the spindle, *h*, and *n* is the operating-lever. Normally the conical-head, *i*, bears against the head, e^1, of the rod, *e*, so that no sparking takes place. At the moment at which ignition is to take place, the lever, *n*, moves the spindle, *h*, away from the rod, *e*, thus enabling the passage of the spark to take place. The backward movement of the spindle, *h*, causes the conical-head, *i*, to close upon the seat, *m*, thus preventing the escape around the spindle, *h*, of gas from the chamber, *a*.—February 14th, 1906.

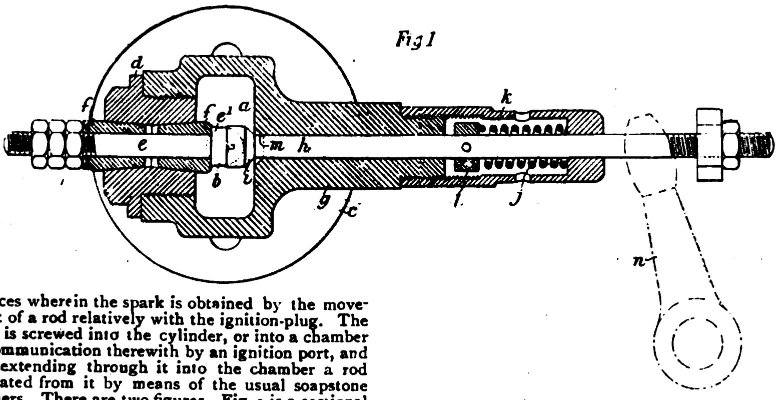

Fig 1

2492. 7th February, 1905. Improvements in Internal Combustion Engines. The British Thomson-Houston Co., Ltd., 83, Cannon Street, London, E.C. A communication from the General Electric Co. of Schenectady, U.S.A. This invention relates to an engine having some features in common with the explosion and compression type of engine and others in common with constant pressure engines. In operation the invention utilises the principle of a constant pressure engine in that it compresses, either in power cylinder or in a separate cylinder, a quantity of air and stores the same under pressure in a reservoir. There are thirteen figures. Fig. 1 is an elevation, partly in section, of an engine. W is a fly-wheel of the engine mounted upon a shaft, upon which a crank, K, is fixed. The crank, K, is moved by a connecting-rod jointed to a piston-rod, P^2, working in a cylinder and having a piston, P, P^1, attached. C is a water-jacket. The portion, C^1, which may be heat-insulated from C, is allowed to attain a fairly high temperature. The piston itself is in two sections, and the section, P, is comparatively cool, being in contact with the water-jacketed cylinder walls of C, and it has grooves in its exterior with packing rings. Section, P^1, is borne upon section, P, and is made of refractory metal, such as cast nickel or cast iron, and it may be heat-insulated from section, P, and filled with loose asbestos or some other packing. At the back of the cylinder and fastened to the back cylinder head is a chamber, H, which can be heated externally to a red heat. It communicates with the cylinder space by a neck. A jet, J, is mounted so as to inject at proper intervals a fine stream of hydrocarbon oil or vapour, the jet being so fine as to divide it up into a spray-like condition. The jet, J, is fed by an oil pipe, *q*, and the check valve, *t*, is mounted near the jet to prevent regurgitation. The pipe, *q*, leads from oil-pump, F^2, immersed in a fuel receptacle, F. The oil-pump, F^2, is operated by a piston-rod, O^2, set in motion by a lever, *l*, acting against a spring, Z^3, the lever, *l*, being a bent lever, and being prevented from moving too far by a stop, s^2. The lever, *l*, is actuated by an upright lever, M^2, through the agency of the compressed spring, Z^2, and at the upper end of the lever, M^2, is a roller which runs upon cam, K^2, upon the main shaft. The lever, M^2, has a double function, as it also sets in motion the long rod, r^1, to open valve, S^1, through the agency of lever, L, and it may be returned by suitable springs. The cam, K^2, acts upon another lever, M, which reciprocates rod, r^2, which, acting on lever, L^2, operates the exhaust-valve, E, of the engine at suitable intervals. At A and A^2, are right and left threaded connectors whereby the adjustment of the effective lengths of rods, r^1, r^2, may be easily accomplished. At I, in cylinder, C, is an inlet-valve closed by a light spring. Z is the outlet valve, also closed by a light spring for compressed air, and a passage is provided communicating from the cylinder space to the reservoir, T, which is an air-tight enclosure capable of holding air at considerable pressure, several atmospheres at least. Air can be admitted from T through a valve, V, opened by a bell-crank lever, U, and nut, S^2, upon a packed screw, H^2, serving as a controlling handle. A check-valve, S, is inserted in the passage from valve, V, up to the cylinder for the purpose of checking any vapours from moving backward towards the tank, T. A small regenerator, R, is introduced, consisting of material with fine interstices for the passage of hot gases from the cylinder and for the storage of the heat therefrom, which heat is again taken up on the admission of the incoming air from the tank to the cylinder, C. An oil-cup, o^3, is mounted so as to enable a little lubricating oil to be admitted to the engine with the indrawn air through valve, I. The piston, in moving forward, compresses the air in front of it forcing it through valve, Z.—February 14th, 1906.

THE TARGA FLORIO IN SICILY.—The scenery through which this important Tourist Car Race will take place on May 6th, is of a very varied character, embracing the most delightful sylvan views, and some very wild and mountainous country. Our views above, and elsewhere in "The Automotor Journal" this week, convey some idea of the test in store for those who take part, the acutely winding roads being a special feature of the selected course. The upper photo shows the Convent of Petralia Sofrana, and the lower one the twisting road in the Valley of Caltavuturo.

PASSING EVENTS.

Motor 'Buses Going too Fast.

The London Road Car Company have been the victims—we mean the defendants—in an action by the police for exceeding the limit of 12 miles an hour for motor 'buses, in which some of the strangest evidence ever relied upon in a court of law was tendered. The police said that some of the Company's motor 'buses went at more than 12 miles an hour, which they are not permitted by the regulations of the Local Government Board to do. The defence of the Company was that it was impossible for the 'buses to exceed that limit, as they were provided with a special governor which immediately cut down the speed of the engine when it had been reached. The magistrate, Mr. Plowden, was much impressed by this, but the summonses were adjourned to enable the police to ascertain whether the governors were reliable as stated or not. As the result of their investigations they maintained that the governors could be tampered with, whereas the chronographs were absolutely reliable, and they produced, in support of the latter contention, the actual manufacturer of these instruments, a Mr. Meader, who is a watchmaker of Albany Street, Regent's Park, who said that, speaking from twenty years' experience, the chronographs *supplied by him* to the police and other Government officers were *infallible* instruments. Mr. Plowden, who apparently accepted the alleged infallibility of Mr. Meader's chronographs as maintained by himself, and as the result of the police investigations doubted the infallibility of the governors on the motor 'buses, particularly as the defendants had not attempted to bring evidence in the governors' support. He accordingly convicted the defendant Company. We cannot help wondering whether it is customary in police courts to accept the evidence of a manufacturer in favour of his own contrivances as fair and unprejudiced. Would any reasonable person have expected Mr. Meader to say that his chronographs were *not* reliable, and that in placing reliance upon them the police were likely to commit a serious error? Had he said so, he might as well, for all practical purposes, have put up the shutters at Albany Street and declared so much in the £. Surely it was a complete travesty of justice to accept evidence of this kind. Only that of an independent expert should be considered for a moment, while after all, even with the best chronograph, it is more a question how it is used than of the perfection of the particular instrument employed.

◆ ◆ ◆

The Wrong Way to Tackle the Subject.

In spite of the idiosyncracies of the evidence, however, we believe that this prosecution was an attempt on the part of the police, and perhaps a well-intentioned one, to curtail the evil to which we have on previous occasions referred. We mean the racing on London streets between the motor 'buses of rival companies, and the nursing of the new vehicles by motor 'buses put on the streets by old companies, apparently expressly for that purpose. Whether they secure convictions or not, we think the police in endeavouring to stop such malpractices, are adopting the wrong method in making it merely a question of speed. They are obviously cases which come under the first section of the Act, about "driving to the danger of the public," and the practice is objectionable, not so much on account of the precise speed attained, as owing to the way in which the whole campaign is conducted, it is calculated from start to finish to bring the public, whether as passengers on the 'buses, users of other vehicles, or ordinary pedestrians walking about the streets, into serious danger. The speed of 12 miles an hour to which motor 'buses are restricted is, after all, an arbitrary limitation, particularly in view of the fact that steps have been taken to permit a maximum speed of 16 miles an hour to the County Council's trams. There is accordingly something invidious in basing a prosecution on this point only, whereas if the appeal were made by the police to the first section of the Act—a section which is designed to protect the public against exactly this sort of thing—the public would at once see that these prosecutions were designed to prevent a growing evil, and were not merely part of the general police campaign against self-propelled traffic, which has excited so much derision and contempt.

◆ ◆ ◆

A Result of Municipal Trading.

We referred recently to the fight between the Birkenhead Corporation and the Mersey Railway Company, in regard to the motor 'bus service which the railway company had organised to bring the passengers to its station. This was done, it will be remembered, because, it was stated, the Corporation endeavoured to starve the railway company by so arranging its tramway and ferry service across the Mersey as not to suit the trains. The matter was brought into the Court of Chancery, before Mr. Justice Warrington, and the learned judge decided that it was a case which came under the decision of the House of Lords, in regard to the London County Council 'buses which used to run from the tramway termini across Westminster and Waterloo Bridges. He accordingly granted an injunction to the Birkenhead Corporation, restraining the railway company from running their motor 'buses. Needless to say the railway company is appealing, so that the matter is not yet finally decided.

◆ ◆ ◆

Of General Importance.

The subject is one of more universal applicability and importance than it may at first sight appear to be. It is not merely a question of a fight between one particular corporation and one particular railway company, but it involves quite a number of similar cases where railway companies are running motor 'buses in districts in which corporations happen to possess Parliamentary powers of catering for public traffic. In fact, if universally applied it might affect quite a large number of those railway extensions, by means of motor 'bus, which are giving the greatest satisfaction to the public in many places. We are sure, therefore, that there will be no lack of funds to support the railway company's appeal, and that if the judgment is adverse to them in the Court of Appeal, the case will ultimately be taken to the House of Lords. Whether the case is on all fours with the London County Council case, which was decided in a particular way, mainly owing to the influence of the late Lord Chancellor, or not, is one which their lordships ought certainly to have an opportunity of pronouncing upon *de novo*.

Against Unlimited Appeal.

"Arising out of this," we are glad to embrace the opportunity of protesting once more against the unlimited right of appeal which prevails in this country. It benefits the lawyers, no doubt, but it is hard to see that it benefits anybody else. The sensible arrangement prevails in Germany that appeal to a higher tribunal is only permissible where the Court of First Instance and the Court of First Appeal differ in their opinions. We have previously advocated a similar system in this country. That would mean that appeal to the House of Lords, the most expensive form of litigation existing, would only be permissible where the Court of First Instance and the Court of Appeal differed in their views. Such an arrangement would be a distinct benefit to the public, however unsatisfactory it might be to the legal profession, and some day we hope to see a general Press campaign in favour of this most necessary and salutary reform in our legal procedure.

◆ ◆ ◆

The Metric System in Great Britain.

Whenever an opportunity has offered, we have always advocated, with all our might, the importance of bringing Great Britain into harmony with the Continental nations, by the adoption of the metric system of weights, measures, and coinage, and have also insisted on the unquestionable advantage to the commercial and technical men of the country that would result from its general and compulsory adoption. There is no more progressive Member of the House of Commons than Mr. Henry Norman. He has for long been a powerful influence in the great Liberal party, and, as everybody knows, is, at the same time, one of our most ardent motorists. In his periodical, *The World's Work*, he has done yeoman service for the automobile movement, and he has just contributed to *Scribner's Magazine* an absorbing and enthusiastic automobile article, entitled "The Flowing Road."

Mr. Norman is nothing if not progressive, and he naturally wishes to see the metric system, which has for some time been legal, made compulsory. Accordingly, therefore, he sought an interview with the Prime Minister on the subject, and asked Sir Henry Campbell-Bannerman whether he would give time to pass a Bill to make the metric system compulsory, or, failing that, appoint a small Committee to enquire whether the change could not be effected with comparatively little opposition. He received a perfect *non possumus* reply, and, as he observes, this uncompromising general negative to the proposal forms the most "sweeping refusal such a proposal has received for many years, and it is the more disappointing as coming from the most progressive of recent Prime Ministers." It is scarcely worth while to reproduce the arguments in favour of rendering the metric system compulsory. The topic has been the subject of such exhaustive discussion in the Press, our present ludicrous medley of weights and measures has been for so long a complete laughing-stock of our Continental neighbours, such a source of trouble and confusion to everyone who has to make calculations, to engineers, chemists, accountants, book-keepers, merchants, manufacturers, and business men generally, that the whole thing is really past discussion. The country in fact, and Parliament, are in the position of a man who is firmly convinced that he is in need of a bath, but cannot prevail upon himself to take the necessary plunge, and in such a case, it is not argument that is needed—but a good forcible push.

◆ ◆ ◆

A Gloomy Lookout for the Ratepayers.

For a long time past we have warned the London County Council and other municipal authorities that, by undertaking their colossal expenditure on electric trams—which has been the subject of so much discussion in the Press generally—and neglecting the possibilities of the motor 'bus, they were putting the ratepayers' money on the wrong horse. There is not only the enormous capital expenditure—so huge, in fact, that it is likely to cripple even the wealthiest city in the world—but there is the much more serious question of what will happen if the tramways fail to pay owing to the competition of the motor omnibus. That this is no mere fantasy of interested automobilists is pretty clearly shown from what is going on abroad. Owing to this cause Berlin has decided to spend no more money on electric tramways. Munich is considering the adoption of municipal service of motor omnibuses, and the same means of locomotion are being adopted even in such out-of-the-way places as the Tyrol. It must be remembered that not till two more years have elapsed will the London County Council's system of electric trams be completed. Those who have seen what the development of the motor 'bus has been during the last year will hesitate even to guess to what extent its capabilities may develop in the next two years, and when the finishing touch is put to the great tramway system it is not at all impossible that it will be found to be hopelessly out of date and outclassed by the motor 'bus.

* * * *

Motor Car Legislation.

IN the House of Lords on Tuesday, Lord Montagu of Beaulieu asked the question whether, if the Royal Commission on Motor Cars reported before Easter, the Government could promise a Bill on the subject during the session. In order to avoid hasty legislation, he suggested that the existing Act, in spite of its imperfections, should be extended for another year, *i.e.*, brought under the Expiring Statutes Continuance Act. Earl Russell expressed the hope that the present Act would not be included in the Expiring Statutes Continuance Act indefinitely. In reply, Earl Carrington stated that it was at present impossible to say when the Royal Commission would make its report, and therefore impossible for the Government to make any announcement. There would, he continued, be neither delay nor undue haste, and if the Committee were unable to report in time for a new Bill to be brought in this year, the course proposed by Lord Montagu would be adopted. This, it will be remembered, is the course which we last week indicated as the one likely to be taken.

Another Service of Municipal Motor 'Buses.

THE Tramways Committee of the Nottingham Corporation, which supervised an extended system of electric trams, have taken a notable step of introducing motor 'buses, to give travelling facilities to the dense population in what is known as the Carlton Road district, and are accordingly commencing a service of motor 'buses from the great Market Place to the Carlton Road. The 'buses, which are being supplied by Messrs. Thornycroft and Co., have been on order some time. They are to be delivered this week, so the service will soon be in working order.

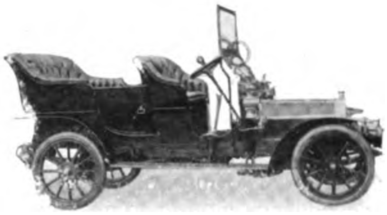
How to Recognise the Cars of To-day.

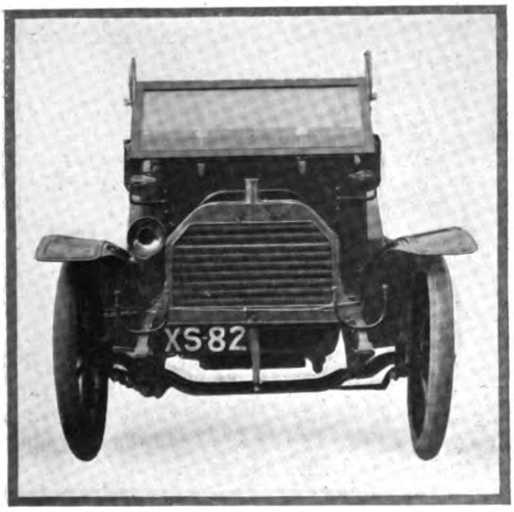
(No. 11).

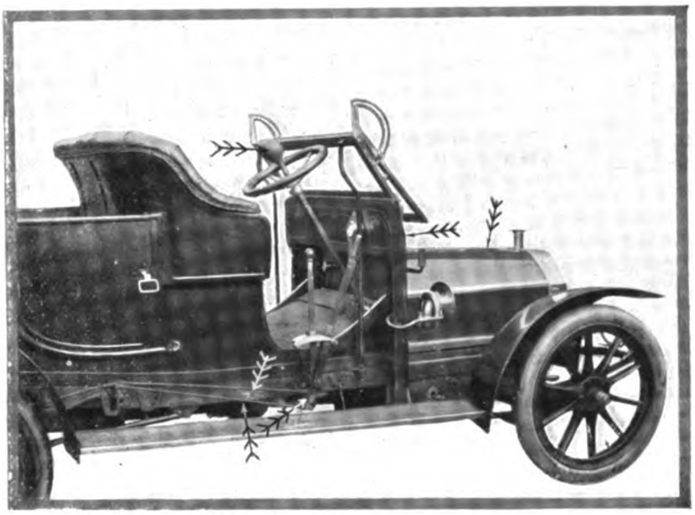
The New Arrol-Johnston

(BRITISH)

12-15 & 24-30 H.P.







On the smaller model the BONNET is BROADER THAN IT IS HIGH. In other respects the characteristics of both are alike. The BULB FOR THE HORN projects from the centre of the steering wheel, and the COMPENSATING GEAR FOR THE SIDE BRAKES is fitted to the lower end of the hand lever. Owing to the relatively greater height of the frame from the ground, these cars have the appearance of being very low-built.

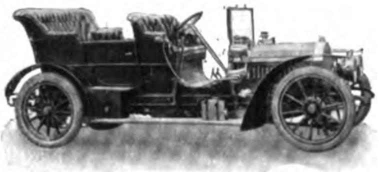
* * *

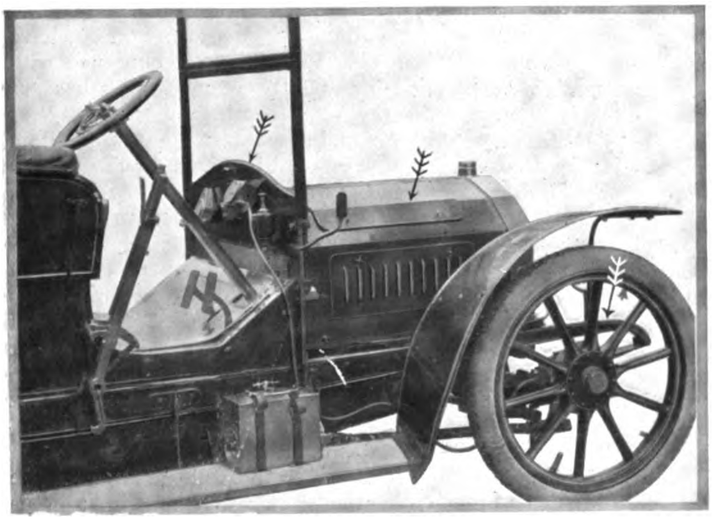
(No. 12).

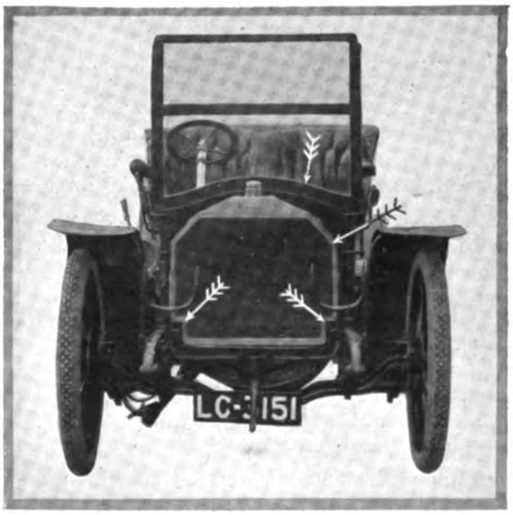
The Crossley

(BRITISH ENGINE)

22 H.P. & 40 H.P.







At the bottom corners, the RADIATOR IS UNDERCUT to rest upon the frame, and, except at the top, the TUBES EXTEND CLOSE UP TO THE EDGE. Although not multi-jointed, the SHAPE OF THE BONNET suggests that form of construction. The LEVERS and PEDALS resemble those of a "MERCEDES" car, but the CURVED-TOPPED DASH is comparatively free of multiple-feed lubricator fittings. Both in front and behind, the SPRING-HORNS project considerably.

FAIR PLAY?

THE WOLSELEY COMPANY AND "THE AUTOMOTOR JOURNAL."

THE AUTOMOTOR JOURNAL has always stood for fair play, independence and impartiality, even in the dark and doubtful days when the modern automobile movement was inaugurated, and this attitude has been maintained even in times when the prosperity of the movement was the plaything of financiers of doubtful intentions and company promoters who proved its worst enemies. The motto of *sans peur et sans reproche* which has topped the flood for nearly a decade of changeful and adventurous years, we are not going to lower now, when the movement has entered on a period of decided prosperity. Above all, we have a strong objection—the English objection—to anything presenting even a suspicion of coercion, particularly if it is in any way directed against what we have always regarded as our duty, of seeing fair play between our supporters, readers, and contributors.

There are necessarily drawbacks, commercially, to conducting a journal in a thoroughly impartial and straightforward spirit, and these we are at all times prepared to accept with a good grace. When, however, they take the form of attacks directed against the independence of the journal, we think it is time to make public protest. A case of this character has just occurred, and so pronounced is it that we feel compelled to draw general attention to it in the interests of the automobile industry and of motorists generally, especially as it concerns one of the best-known firms of manufacturers, who have always earned world-wide respect by their consistent fair dealing with everyone—we refer to the Wolseley Tool and Motor Car Company.

Many of our readers will notice the absence of the Wolseley Company's usual advertisement from this number of THE AUTOMOTOR JOURNAL, and we feel convinced that nearly every reader will feel indignant when they learn that the withdrawal of the advertisement arose out of a controversy in our columns between that Company and Mr. S. F. Edge (which was of the Wolseley Company's own seeking), and that the following are the facts of the case:—

Two weeks ago, through their General Manager, Mr. Siddeley, very strong exception was taken to a public statement made by Mr. S. F. Edge concerning the improved outlook of British manufacturers in competition with imported cars, in the form of a strongly-worded letter on the subject, sent for publication to the motor Press. That letter was published in these columns, but not before we had taken the trouble to put ourselves in communication with one of the Company's representatives (in Mr. Siddeley's absence abroad), and had been assured that the matter had been well considered in all its bearings, and that Mr. Siddeley was quite prepared to meet any adverse replies.

Not unnaturally, the reply from Mr. Edge was of an extremely trenchant character, but much as we disliked the whole spirit of the controversy, we had no alternative—after having printed the original letter—and consequently Mr. Edge's letter was published in this Journal last week.

Next comes the sequel—a letter from the Wolseley Company to the publishers of THE AUTOMOTOR JOURNAL—which we now give in full as follows:—

9th March, 1906.

Messrs. F. King and Co., Ltd.,
44, St. Martin's Lane, W.C.

DEAR SIRS,—With reference to the advertisement at present appearing in THE AUTOMOTOR JOURNAL, kindly take this letter as a cancellation of any order standing at the present time in regard to same, as we do not wish our advertisement to again appear therein.

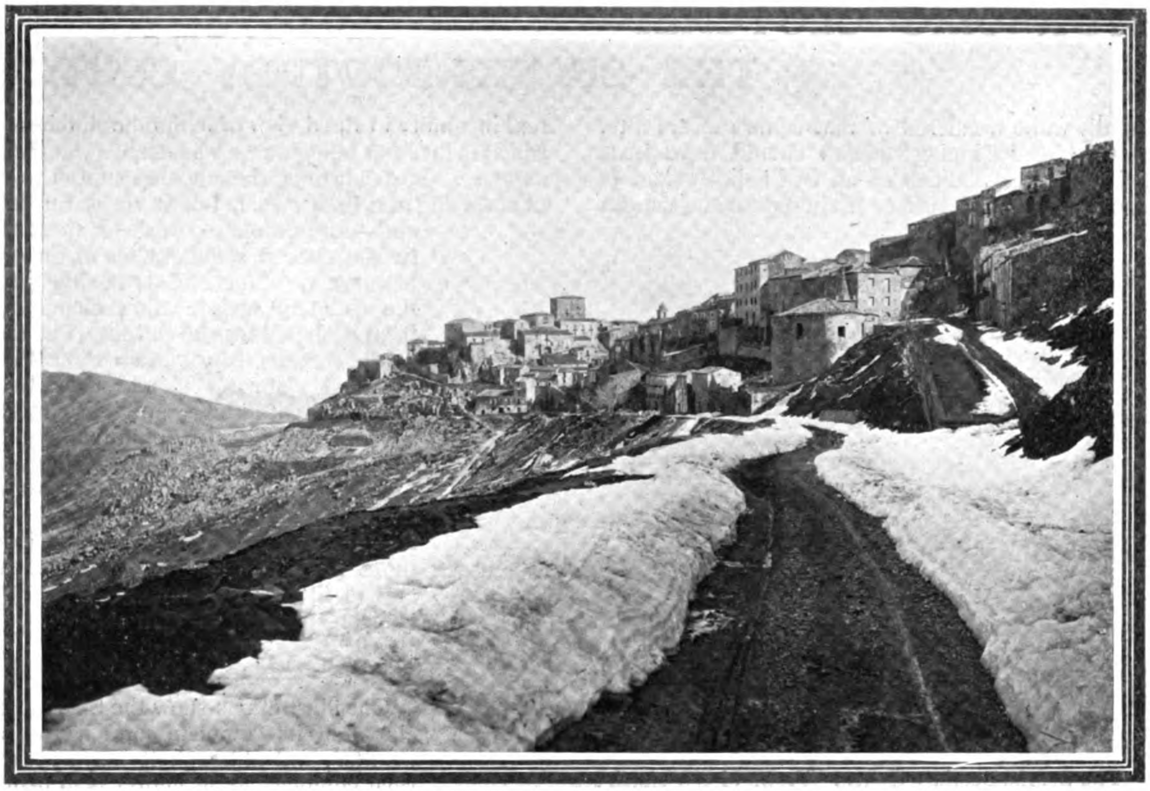
Yours faithfully,
For THE WOLSELEY TOOL AND MOTOR COMPANY, LTD.
(*Signed*) J. D. SIDDELEY,
General Manager.

It only remains to say that subsequently, when communicating with the general manager personally on the telephone, we were unhesitatingly informed that the action taken by his company was wholly and solely due to our having published Mr. Edge's reply.

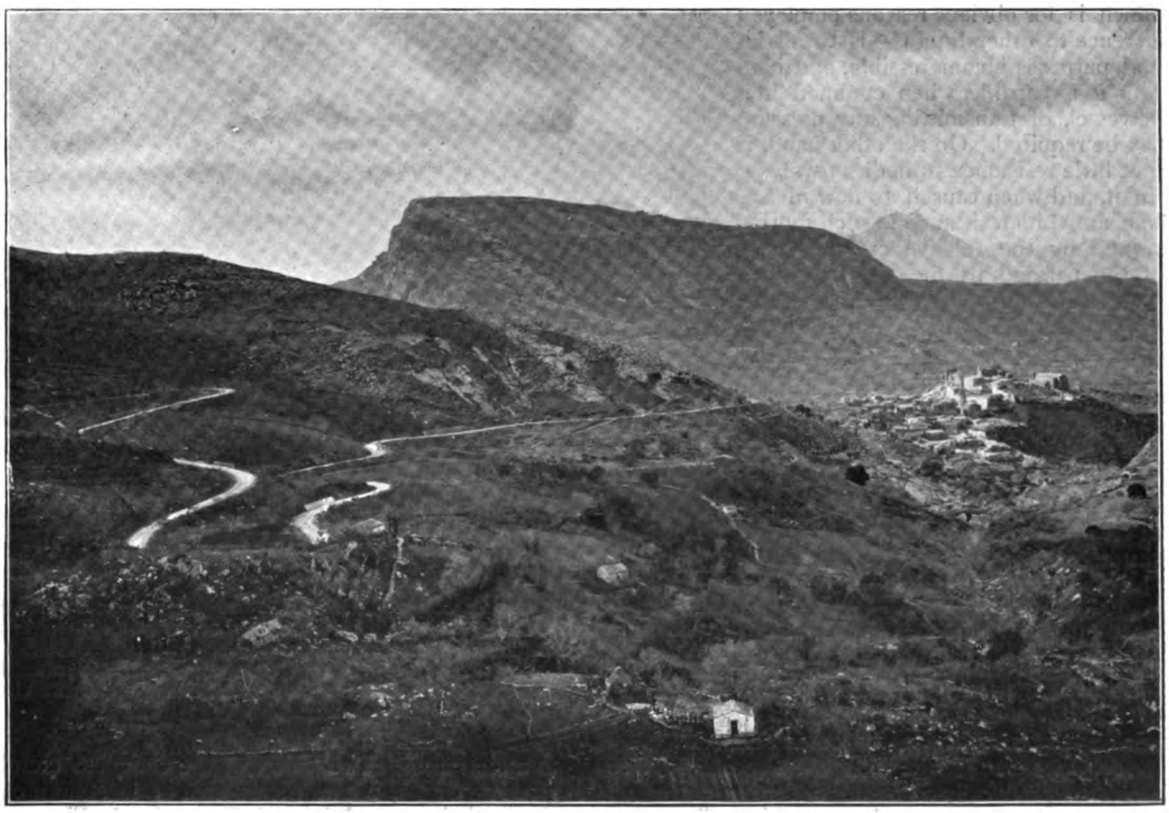
Beyond old association with those responsible for building up that important concern, the mere fact that the Wolseley Company's support has been withdrawn from us is of little moment, as compared with the all-important reason which has brought it about. We hardly think our worst enemies would suggest that THE AUTOMOTOR JOURNAL has ever been conducted, during the ten years of its existence, other than in an absolutely impartial and, we hope, judicious manner. We have always protested against personalities or veiled attacks in the correspondence columns, which must inevitably lead to retaliation and more personalities, and, as far as possible, have always kept such communications out of our columns. Circumstances, however, arise at times when, in justice to those concerned, letters containing sweeping statements, amounting almost to direct accusations, have to be admitted to our columns, and in accordance with British ideas of fair play, a hearing necessarily has *per contra* to be given to the other side if they so elect.

It is somewhat alarming, in the interests of the freedom of the Press, if grounds should be given for the idea to prevail that no journal can be run on impartial lines, but that it is liable to lose the support of any advertising firms—even though it is obviously to their loss also—if in the correspondence columns they happen to get an "answer back." However much the proprietors of this Journal may regret losing the moral and commercial support of the Wolseley Company, our readers may rest assured that they have no intention of attempting to coerce the Editorial department, in the conduct of THE AUTOMOTOR JOURNAL, into sacrificing the supreme interests of its readers and the industry.

It is with a view to as far as possible preventing the recurrence of such incidents, and so doing what in us lies to preserve the proper and dignified independence of the automobile Press, that we have made this incident public.



THE TARGA FLORIO RACE IN SICILY.—On the course selected for the cars. The entrance to Geraci-Siculo.



THE TARGA FLORIO RACE IN SICILY.—In our Frontispiece we show a very intricate winding road near Caltavuturo. Another serpentine portion of the course on the road near Collesano, is seen in the above photograph. This picture also gives a good idea of the rugged character of the country.

HYDRAULIC CLUTCHES— THE SPARKS-BOOTHBY CLUTCH.

It is hardly to be wondered at that some seekers after a good type of "slipping" clutch should have been attracted by the possibilities of an hydraulic system in preference to relying on surface friction pure and simple.

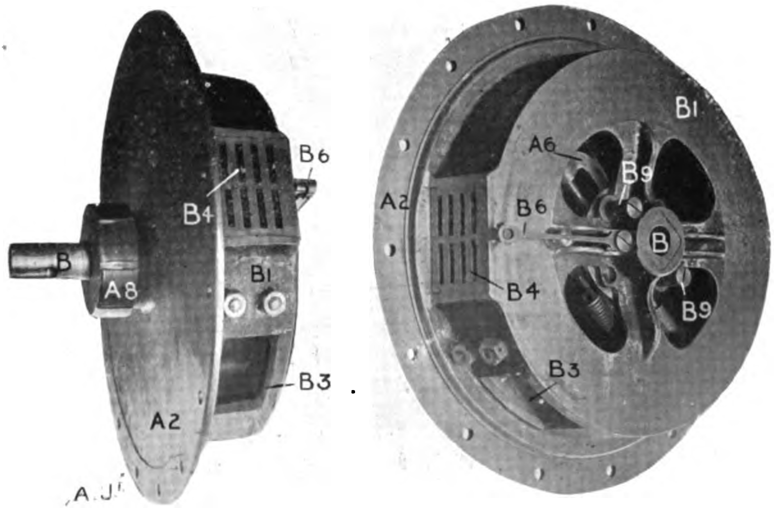


Fig. 1.—The Sparks-Boothby Clutch. Views of the clutch complete ready for fixing to the fly-wheel. Parts of both members of the clutch are visible in this view. Although apparently solid, the casting, B^1, is separate from the casting, A^2, which is bolted to the fly-wheel.

Oil—which is for obvious reasons employed in preference to other liquids—is to all intents and purposes incompressible, and consequently it is capable, when confined in a suitable vessel, of transmitting any pressure that may be required. On the other hand, it offers but little resistance to bodies revolving freely in it, and when caused to flow in any specific channel its resistance to such motion is governed by the relative cross-sectional area of the passage to the volume which is being forced through in a given time. Suitably constructed, therefore, an hydraulic clutch might well possess the three attributes most desired, *i.e.*, absolute freedom when not transmitting any power, gradually variable resistance (easily controlled slip), and positive dead-lock when fully engaged.

Principles of an Hydraulic System.

Such a mechanism would almost of necessity comprise some kind of pump that might be made to circulate the oil, combined with some form of throttle-valve, which could conveniently be caused to vary the effective area of the passage, and so introduce more or less resistance to the free flow of the oil. If the flow of oil were quite stopped, the entire apparatus virtually becomes one solid body, whereas if the flow were perfectly free there would be practically no tendency for the "driven" portion of the clutch to compel the "driving" portion to revolve with it. It is, of course, the adaptation of this simple principle to motor car use that demands real ingenuity in the design of hydraulic clutches—a task which is far from being as easy as some motorists might suppose. Not only must the whole apparatus be capable of revolving at a high speed, but it must be compact, and—for automobile work—it must conform to the special requirements of an ordinary motor car. Mechanisms having pumps of the ordinary reciprocating character, have been designed for the purpose, but there are many reasons why certain difficulties of a practical character should have been experienced with them, and it is more than probable that a rotary pump of one kind or another will always be found more suitable for this sort of work. Such at least is the opinion of those responsible for the Sparks-Boothby hydraulic clutch, which is one of those most to the fore at the present day, and is fitted to a standard type of petrol vehicle—the new Morgan car.

Action of the Clutch.

Our illustrations show the Sparks-Boothby clutch in its complete form as well as dismantled, and although it may appear somewhat complicated, its action is in reality very simple, and its adaptation of the principle previously explained is by no means difficult to understand. Two views of the complete clutch are given in Fig. 1, but a better idea of its action can be obtained from the left hand illustration in Fig. 2, which shows the clutch actually bolted to the engine fly-wheel, part of which has been cut away in order to expose the

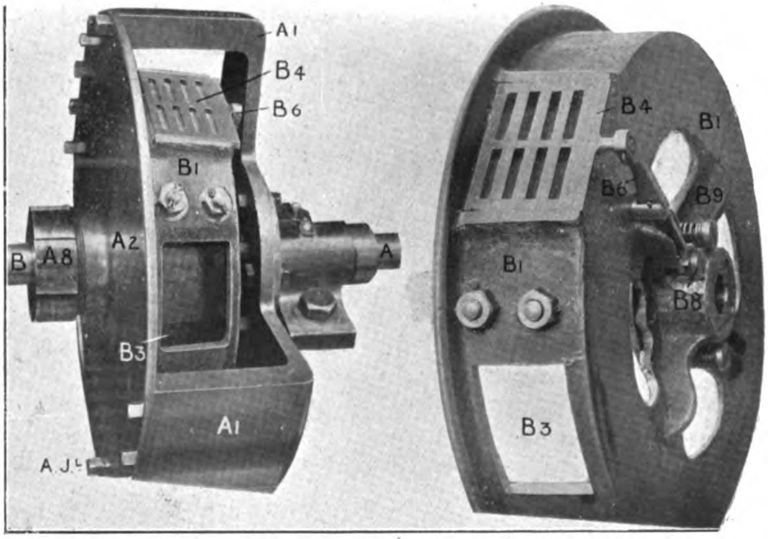

Fig. 2.—The Sparks-Boothby Clutch. On the left is a view of a model showing the clutch in place within the fly-wheel of an engine. It is the casting B^1, which forms the clutch-driven member, this is fixed to the shaft, B. On the right is a larger view of part of this inner member, B^1, showing the grid-valve, B^4, and its mechanism by which the clutch is operated.

interior. As usual, there must, of course, be two main members to the clutch, the engine-driven portion and the clutch-driven portion, and it is the various parts of these that are denoted by the letters A and B respectively.

In this clutch, the pump-chamber, C—which is most clearly illustrated in the sectional line drawing, Fig. 3—is of annular shape, but there is a small division piece, B^2, which prevents the annulus being complete. Small paddles, A^4, constitute the pump-vanes, and these are carried by part of the driving member. The entire fly-wheel is filled with oil, and directly the engine is started the pump-vanes, A^4, begin circulating the oil, which is forced out of the pump-chamber, C, through the opening, B^3, and thus into the outer passages, C^1, from which it passes back into the pump-chamber through the valve, B^4. So long as the valve, B^4, remains open, thus allowing free circulation to take place, the clutch remains disengaged, but if the valve, B^4, is partly closed, a back pressure is set up which resolves itself into a direct thrust through the intervening column of oil, between one of the paddles, A^4, and the stop, B^2. Under such circumstances the shaft, B, to which the stop, B^2, is indirectly attached, is consequently driven by the engine-shaft, A, which carries the paddles, A^4, but it is only when the valve, B^4, is quite closed that the speed of rotation of the two shafts is compelled to be the same, because under all other conditions the partial circulation of the oil allows relative slip to take place.

Two other views (Figs. 4 and 5), showing respectively the two main portions of the clutch separately, complete our series of illustrations, which render the details of the construction of the clutch almost self-evident. It will be noticed that the two principal members somewhat resemble those of the ordinary metal cone friction-clutch, and, as a matter of fact, a similar sliding to and fro action does take place in the clutch just when it is being engaged or finally disengaged. That is to say, the action of the throttle-valve is supplemented, during the final stage of freeing the clutch, by a positive separation of the two members, so that they can run quite freely in their oil bath.

Details of Construction.

Although the general arrangement of the parts of the clutch is very clearly shown by the photographs and drawings, some further description of the constructional details will, nevertheless, no doubt, be useful. In order to make the clutch occupy as little room as possible it is so constructed that it can be enclosed inside the fly-wheel, A^1, as shown in Figs. 2 and 3. Leaving the fly-wheel itself out of consideration for the moment, however, the main engine-driven member of the clutch is represented by the plate, A^2, which is cast solid with the conical ring, A^3. This plate is, it will be noticed, bolted direct to the fly-wheel when finally in place. Carried by the ring, A^3, are the two paddles, A^4, the exact arrangement of these parts being very clearly illustrated in Fig. 4. Each paddle is cast with an arm, A^6, and these arms spigot into one another in such a way that the two paddles are well guided and supported, when in place. In order to produce the reciprocating motion necessary to enable the paddles to clear the stop, B^2, when the clutch is slipping, the arms, A^6, which are provided with small rollers for the purpose, are drawn down against a cam, B^5, by means of springs, A^7. The cam itself, is, of course, part of the clutch-shaft, B, being keyed direct to it in such a position relatively to the stop, B^2, that the reciprocating motion of the paddles synchronises properly.

(*To be concluded.*)

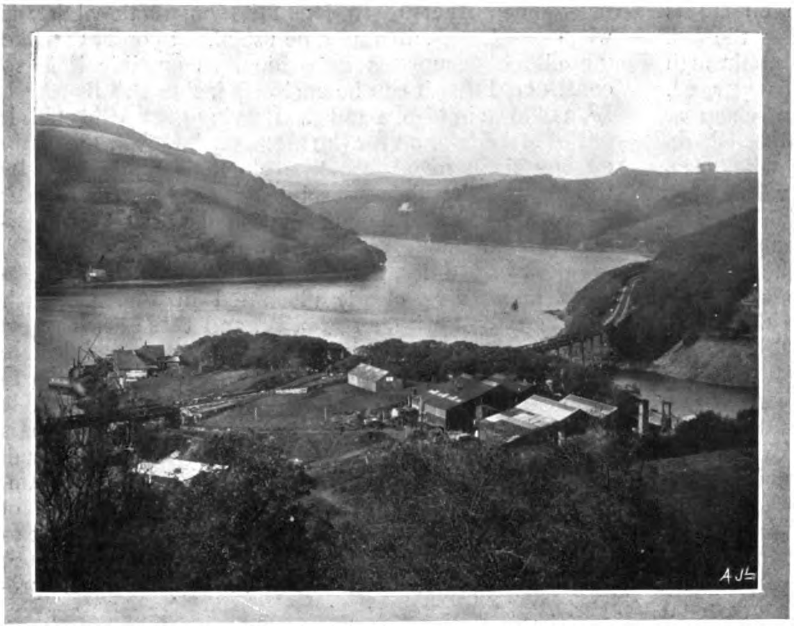
THE SIMPSON AND STRICKLAND STEAM LAUNCHES AND MOTOR BOATS.

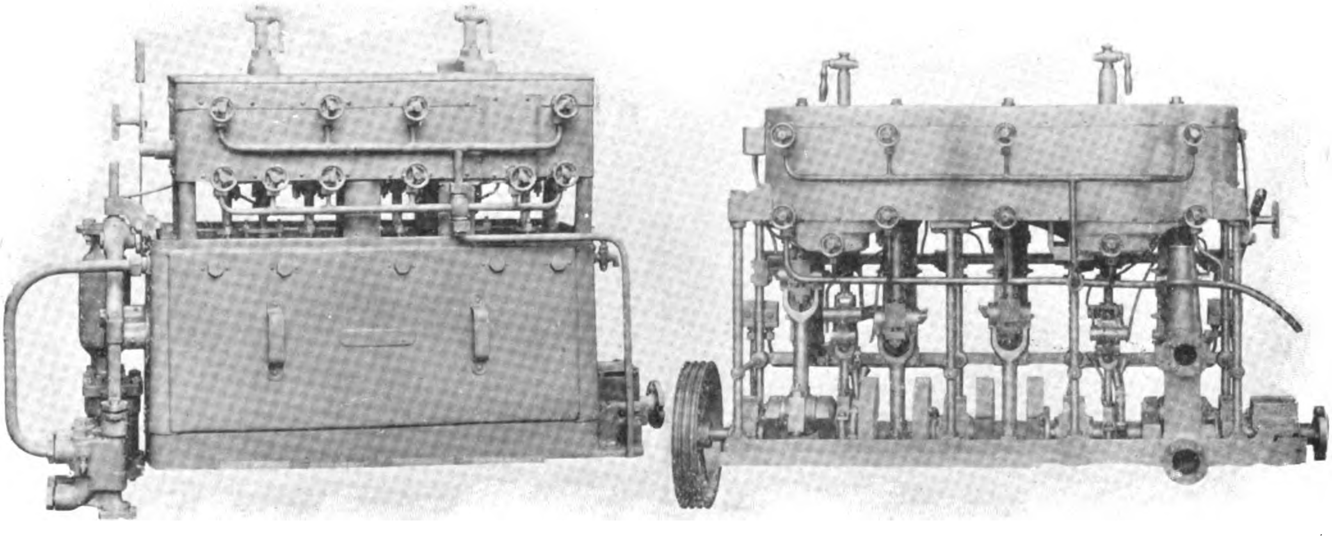
IT is always an excellent sign of the healthy growth of any new industry, when one after another of the large firms, who have already made their names in some kindred and parent engineering business, begin to take an active part in its development. Already such names as Thornycroft and Yarrow are closely associated with the progress of the motor boat, and now that of Simpson, Strickland, and Co.—the well-known builders of steam yachts and high-speed launches—can be added to the list.



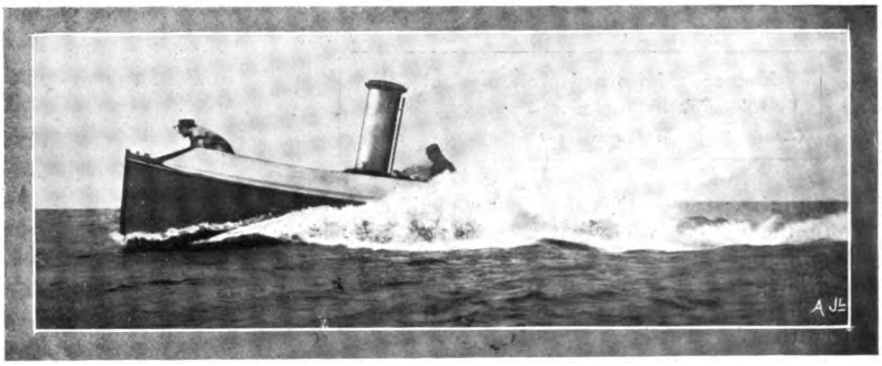
A view of the picturesque estuary at Dartmouth, showing the situation of Messrs. Simpson, Strickland, and Co.'s yacht-building works.

The firm have for some time devoted a good deal of study to the application of internal-combustion engines to marine work, and have kept closely in touch with all that has been going on in the automobile world. They have already taken up the manufacture of petrol motors of 8, 16, and 32-h.p. respectively, these engines having 1, 2, or 4 cylinders of $4\frac{3}{4}$ ins. bore by $5\frac{1}{2}$ ins. stroke. Their experimental work, in this direction has, however, not yet been quite completed, for the intention is to make a very important feature of motor boats, and to equip them with engines that can work on a safer fuel than petrol. It is, perhaps, but natural that a firm which has been able to obtain such excellent results with steam, and have done so much to render it effective, economical, reliable, and durable for marine work, should be very exacting in their requirements, and should wish to be thoroughly convinced of the all-round merits of any new type of power generator before deciding to adopt it on a large scale. But it is, on the other hand, just such manufacturers as these that are best qualified to make motor boats an unqualified success.

We recently had the pleasure of visiting their Dartmouth works, a portion of which are visible in one of our accompanying illustrations. They are extremely well equipped for the manufacture of the boats themselves, as well as of the entire propelling mechanism. Every part is constructed on the premises from the



Views of the "Cross" quadruple expansion 4-crank steam engine, which is built by Messrs. Simpson, Strickland, and Co., at Dartmouth. The engine on the left is of the "closed-in" type, and that on the right of the "open" type.



A 30-ft. yacht's launch, built by Simpson, Strickland, and Co., which in 1900 attained the record speed, for boats of this length, of 19 knots per hour.

raw material, and—both in design and finish—thoroughness struck us as being the prevailing note. Our other illustrations show a special type of quadruple-expansion steam engine of which (amongst several others) they have built many, and also a 30-ft. launch driven at full speed by one of them. The engine, which is extremely well balanced, and is either of the "closed-in" or "open" pattern, has four cranks, two sets of piston-valves, and can run at very high speeds. The successes scored by these makers, in the Reliability Trials at Southampton last year, are evidences to the degree of perfection attained by them with steam, two out of the three gold medals having been awarded to them as well as special awards.

⊕ ⊕ ⊕ ⊕

Some Unsolved Problems in Motor Engineering.

On Wednesday evening of last week, the discussion following upon Lieut-Col. R. E. B. Crompton's paper on this subject was concluded at the Royal United Service Institution, and a large number of members of the Automobile and Cycle Engineers' Institute expressed their views on many of the points raised in the paper. For the most part the speakers were either those who delight to criticise adversely anything or everything that is now included in the standard practice of motor car makers of the day, or those who can avail themselves of such opportune occasions for bringing their own new devices before the notice of the public. There were comparatively few well-known designers of standard vehicles present to defend the accepted methods of the day. Consequently, the most useful remarks—apart from some of a purely general nature—were, perhaps, those made by Mr. Coventry, of the Great Western Railway, who was able to speak with very considerable authority after the enormous amount of experience that he has now had with various types of commercial vehicles. It is unfortunate that there should have been so strong a tendency, at this first discussion of the Automobile and Cycle Engineers' Institute in London, in the direction of the theoretical and academic, rather than the thoroughly practical, but doubtless the very nature of the paper gave the hypercritics their chance. Thus, for instance, there was a fairly strong gathering of electrical engineers present—most of whom have, themselves, done nothing towards the perfection of electrical apparatus on modern cars—and they were apparently just as unanimous in condemning the electrical equipment now employed, as many old-fashioned mechanical engineers always are in condemning all types of transmission gear, regardless of the fact that some of them *do* "work."

THE TARGA FLORIO RACE IN SICILY.—A double turning in the mountain heights.

REVIEWS OF BOOKS.

Motor Vehicles and Motors.—Vol. II.

By W. WORBY BEAUMONT, M.I.C.E., M.I.M.E, M.I.E.E.

(*London: Archibald Constable and Co. Price 42s. net*).

IT is with the purest satisfaction that we hail the appearance of the second volume of Mr. Worby Beaumont's great work on automobilism and automobile construction. There can be no doubt that it is far the most thorough, comprehensive, and satisfactory book on the subject that has yet issued from the press, whether in this country or any other, and every Englishman connected with the automobile movement will be at one with THE AUTOMOTOR JOURNAL in feeling a certain amount of reflected pride in the fact that it has fallen to an English consulting engineer to produce this splendid text-book. The work is likely to appeal to our readers in particular, as the subject-matter is treated with the care, accuracy and thoroughness which appeals to them, while in addition they are specially able to carry the study of the various topics further by following up the references which Mr. W. Worby Beaumont so copiously supplies, for he has, over and over again, referred his readers to the columns of THE AUTOMOTOR JOURNAL for further details. When we say "for further details" we do not for a moment suggest that Mr. Worby Beaumont's chapters are in any degree incomplete. On the contrary, the extraordinary correctness of detail with which he has dealt with such a variety of different subjects, and the remarkably good illustrations which characterise so many of its pages, are among the marvels of the book. But large as the volume is—and the actual letterpress covers some 659 quarto pages—the work would have had to be much more voluminous had he not in every case had to apply perforce the principle of leaving out almost everything that could be omitted.

It is a tremendous testimonial to the marvellous expansion of the automobile industry which the world has seen since Mr. Worby Beaumont's first volume issued from the press, to find that this second volume, which he thought might merely consist of a sort of appendix (comprising some supplementary chapters and engravings)—when he first contemplated writing it, soon after the second edition of its predecessor has appeared—has grown and grown to its present ample proportions.

The first volume comprised what may be termed the principles of automobilism—the general considerations involved in the design and construction of a self-propelled vehicle, its historical development, and the historical retrospect dealing with the predecessors of the modern movement, the old steam cars. To this was added careful descriptions of the most representative types of vehicle of that day—six years ago.

The second volume is quite different. The historic presentment of the subject having been adequately dealt with in the former volume, the subject is (probably to the relief of a good many) omitted entirely from the present work, which in the main consists of descriptions, —needless to say, as we have already remarked, highly workmanlike and accurate descriptions—of the principal existing builds of petrol cars, and in this way constitutes a real second volume and in no respect whatever a mere third edition. Commercial men, too, will no doubt find the exhaustive chapter on the cost of motor transport provide valuable data and principles which they may apply when considering the application of the automobile to regular route service, in which there is special reference to the cost of running motor 'buses, one of the more burning commercial questions of the day.

Several important chapters on more theoretical considerations, based on data which the experience of recent years has furnished, such as the chapters on "Power, Speed, and Tractive Effort," and on "Vibration and Turning Effort," "Overturning and Skidding," "Engine Dimensions, Piston Displacements, and Mean Pressure," of high value and interest to the engineer, are also included, while the data and general observations given on materials, especially steels, employed in car construction, are particularly suggestive and instructive.

Neither these, however, nor some other features in the work, can be expected to be absolutely up to date. The writing of a work with such a scope as this involves a perpetual struggle to keep abreast of a movement that is growing much more rapidly than anyone can write about it, and that, naturally enough, has given rise to a few solecisms, one of which may be quoted by way of illustration:—

> "Mr. Napier has made some cars with 6-cylinder engines, which are of much interest, and a large racing car of the same type, of about 80-h.p. The latter car is provided with only two forward speeds, the engines being relied upon to meet all intermediate requirements."

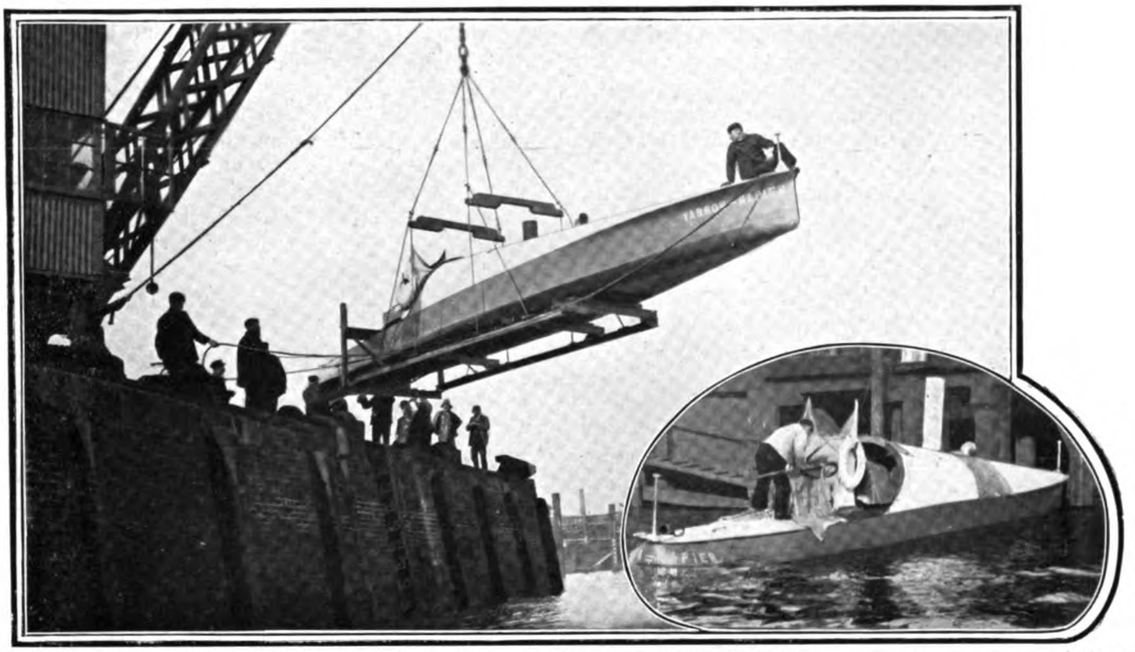
Pages 244 to 252, together with four large plates, are devoted to describing the Napier cars, and it is only by way of an afterthought on the last page and three words on the first page that the 6-cylinder touring cars are mentioned at all. Similarly, too, no reference is made to any other 6-cylinder engine than the "Belsize" model. Considering the way in which the 6-cylinder controversy has for some months been raging and the number of 6 and even 8-cylinder cars now on the market, this would strike the novice who neglected the time factor in the compilation of the treatise as rather ancient and very meagre history, were it not for the accompanying reference to THE AUTOMOTOR JOURNAL for the year 1904.

Most of the criticisms which the work might theoretically invite are therefore inadmissible, as they are evidently due to this same cause. Thus there is at least one vehicle mentioned which is now practically off the market, though at one time it represented the most advanced practice. Nor do we fancy that if Mr. Worby Beaumont were re-writing the work now, he would devote quite so much space to, or, in fact, treat quite so much *au grand serieux*, the electric vehicle. Incidentally, it may be observed that of the cars illustrating this branch of the subject, one was broken up in the year 1903, and that two were not built by the firm to which they are attributed.

In the useful chapter "Engine Dimensions, Piston Displacement, Mean Pressure," we fancy, however, that the table given would be more generally intelligible to the interested reader if, instead of multiplying the cylinder capacity per minute by 2, it had been divided by 2, for the figures would then correspond to what most people think of as the piston displacement in an "Otto" cycle engine, *i.e.*, the amount of mixture sucked in per minute.

But these are trifling matters, and do not to any real extent detract from the immense value of the book as the most comprehensive and reliable work on motor car construction which has yet appeared.

"YARROW-NAPIER."—THE LATEST HIGH-SPEED MOTOR BOAT.

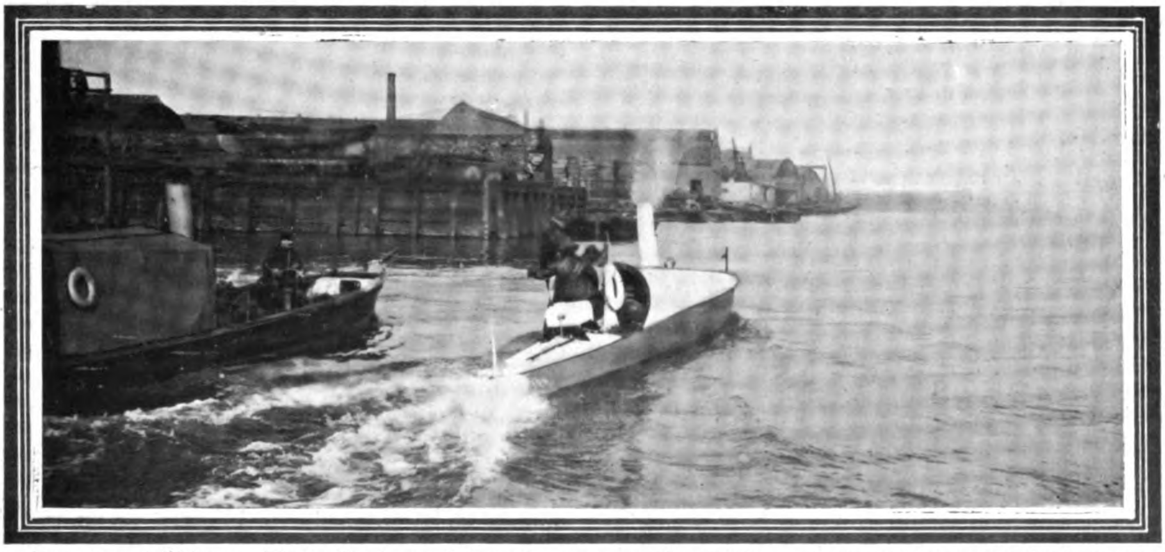


The latest racing motor-boat, "Yarrow-Napier," which replaces "Napier II" of last year. She has been unofficially timed to a mean speed of 27·2 knots, which is over 31 miles per hour, and is already on her way to Monaco for the forthcoming races. Our photographs show the boat being "launched" at the Yarrow works, and afloat in her natural element.

WITH the boating season now rapidly approaching, makers are already launching their new crack craft which are to represent them in the forthcoming sporting events.

Among these is "Yarrow-Napier," which takes the place of the famous "Napier II" of last year, of which a very fully illustrated description appeared in THE AUTOMOTOR JOURNAL of March 11. Her general lines are exactly similar to the old boat, but the hull is constructed of wood, on the Saunders sewn principle, instead of steel. Our illustrations show the general lines of the hull both above and below the water-line, and it will be noticed that the bottom is quite flat. A somewhat more finished appearance is obtained with this boat than with "Napier II," owing to the fact that there is a permanent wooden hood over the engines instead of the canvas cover formerly used. Another small detail which has been dispensed with is the spray guards, but the bow has a more pronounced flare, which answers the same purpose in a neater manner.

Two 75-h.p. engines are employed to drive the boat, each being coupled to its own propeller. Only one



Another view of "Yarrow-Napier," taken while under way. At first sight, anyone would imagine the boat was a "steamer," not only because of the high funnel but on account of the steam actually issuing from it. This steam is caused by the circulating water which is brought into contact with the exhaust gases in order to cool them.

of these is fitted with a reversing gear, however, and when getting under way it is only necessary to start one engine by hand because the motion of the idle propeller through the water develops sufficient turning effort to enable the second motor to be started on the switch. Both engines are of the 4-cylinder type, they each have their enamelled aluminium water-jackets cast in one piece with the upper half of the crank-case, and use cast-iron liners for the cylinder walls. A single bearer runs fore and aft down the centre of the boat for supporting the inside engine-feet, the outside supports being attached directly to the hull. The two engines run in opposite directions, and are so arranged in the boat that their exhaust-valve sides are adjacent. A large exhaust-box, through which the cooling-water passes in contact with the gases, is provided to form a silencer, and the exhaust, after passing through this, can either be discharged under water or through the funnel. This funnel makes the boat look very much like a steam craft, and the delusion is emphasised when exhausting to the atmosphere, owing to the steam which arises from the heated water.

All the general arrangements are very similar to those in "Napier II.," and it will be noticed that the same position has been adopted for the steering-wheel on the after deck, and that a seat is provided for the skipper over one of the petrol tanks. No officially-timed tests have yet been carried out, but during some trial runs her mean speed is given as 27·2 knots (31·2 m.p.h). At this speed, the engines were running normally, and we understand from Mr. S. F. Edge that the boat seemed capable of working under those conditions for an almost indefinite period.

In fact, so satisfied was he with the trials that he has had the boat shipped off to Monaco without delay, and her performances in English waters have, therefore, been of the very briefest duration. The overall dimensions are as follows:—Length 12 metres, beam 5 ft., draught of hull 9 inches, and draught including propellers 2 ft. 6 ins.

* * * *

THE "AUSTIN" LUBRICATION SYSTEM.

LAST week, we described the "Austin" exhaust device which is being fitted to all the new "Austin" touring cars, and now we are able to give some particulars of another feature which is also being incorporated by Mr. Austin with the object of entirely overcoming any ordinary "exhaust troubles." We refer to the lubrication system, by which, it is claimed, that smoky exhaust and foul ignition-plugs are rendered practically impossible. The oil is forced from the main supply tank, which is fixed to the frame near the engine, by a small gear-driven rotary pump to a sight-feed distributor on the dashboard, and thus it is caused to flow to the pistons and to all the bearings of the engine. Subsequently it finds its way down into wells formed in the base of the crank-chamber, and thence it flows back again through filters to the supply tank. Since the driver can always ascertain at a glance whether the pump is working properly or not, there is practically no question as to whether the correct quantity of oil is present inside the crank-chamber.

* * * *

A Novel Point in Motor Car Law.

ONE Lionel Anderson was summoned before Mr. D'Eyncourt for having no lights on his motor car after dark, and for having no light to illuminate his identification plate in the rear—the usual police illegality of making two charges out of the same occurrence. Fortunately he met with a sympathetic magistrate who had a humorous eye for the inconsistencies that have been left in the Act and the Local Government Board Regulations. The regulation under which the summonses were taken out states:—

> "(7) (i) The lamp to be carried attached to the motor car, in pursuance of Section 2 of the Act of 1896, shall be so constructed and placed as to exhibit, during the period between one hour after sunset and one hour before sunrise, a white light visible within a reasonable distance in the direction towards which the motor car is proceeding or is intended to proceed."

Mr. D'Eyncourt held that as the car was at rest and not proceeding, and nobody knew in what direction it was going to proceed, it could not commit the offence of not having a white light visible in the direction in which it was proceeding or was intended to proceed, and the summonses were dismissed accordingly.

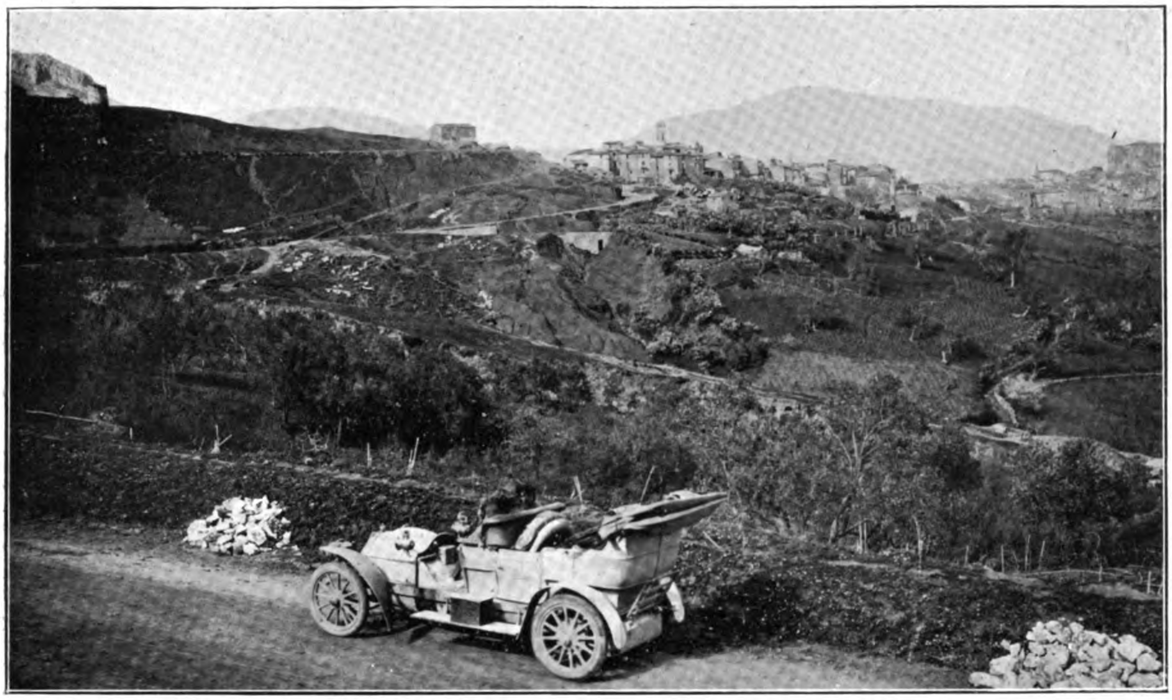
The Results of Bad Example.

WHEN a motor 'bus goes wrong everybody and everything is so astonished that they go wrong likewise and a regular chapter of accidents results. At least this is the conclusion to be drawn from certain phenomena which were observed recently near the corner of the Old Bailey. A "Union Jack" motor 'bus, making its way westwards, collided with a van, the driver of the van being thrown from his seat and sustaining injuries. A boy cyclist was so struck by such an unwonted occurrence that he promptly fell off his bicycle, and he too sustained injuries, while at the same time a philosopher of the pavement, who was viewing these occurrences with curiosity and preparing to record them in a note-book, put his foot through an open coal-hole that was preparing to receive a charge of fuel from a yawning sack, and received injuries to his leg, while another astonished spectator of these catastrophes was run over by a horse-drawn omnibus and was slightly injured in the same part of his anatomy as the gentleman who mistook the open coal-hole for a portion of *terra firma*.

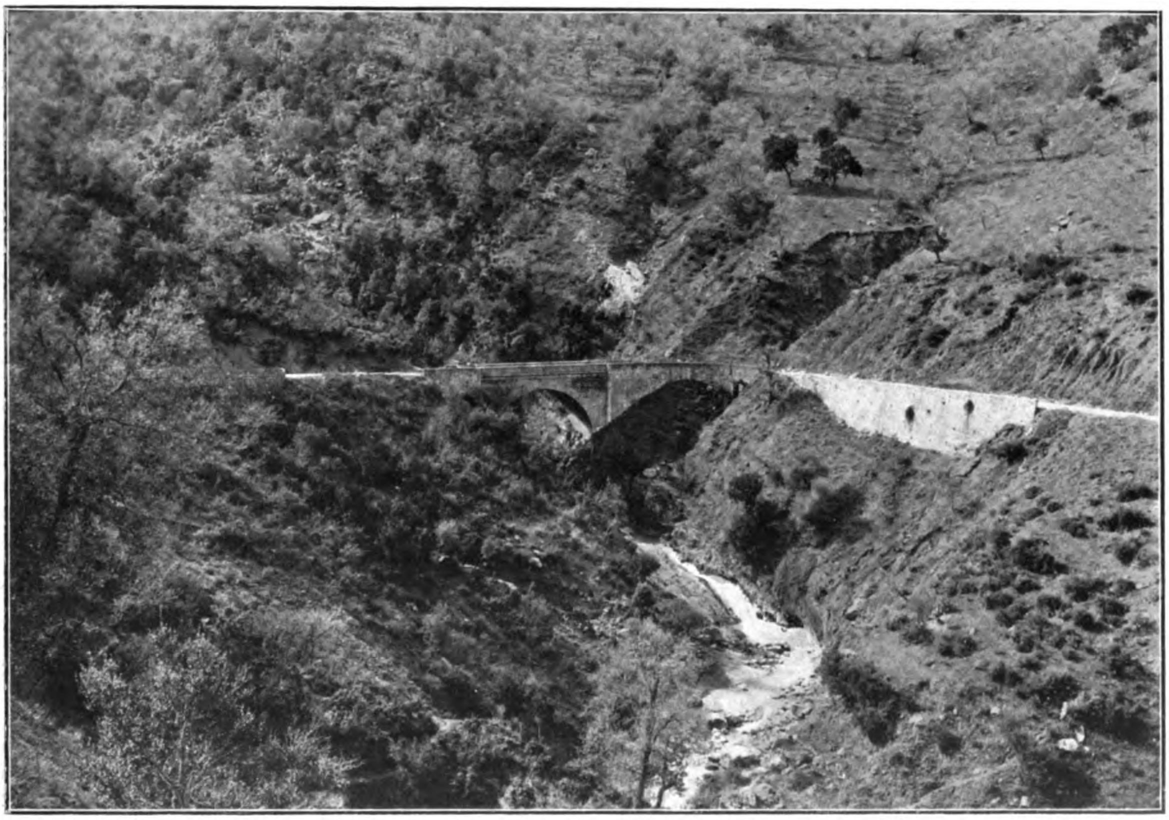
Chasing the Horse by Car.

IN the neighbourhood of North Leach recently, when one of the Automobile Club trials was being conducted, no less than three horses ran away at once. The driver of one of the cars, however, gave a lift to their owner, and finally, by the co-operation of the car, the recalcitrant animals were headed off, and brought back to their labours. The horses of North Leach have since held an indignation meeting, which, it is understood, will probably lead to the passage by the parish council of anti-automobile resolutions at their next meeting.

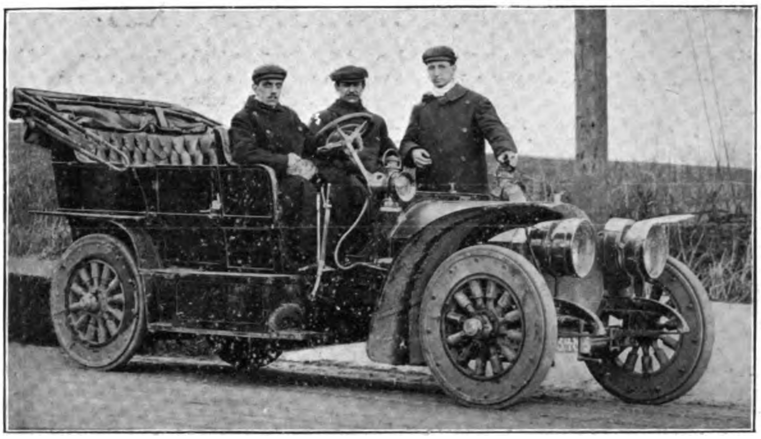
RACES, RECORDS, AND TRIALS.



THE TARGA FLORIO RACE IN SICILY.—The road upon approaching Castelbuona (seen in the distance).



THE TARGA FLORIO RACE IN SICILY.—A striking scene in the mountains near Isnello.



RESILIENT WHEEL TRIAL.—The Pradeau wheels now undergoing a 4,000-mile test, on a 24-h.p. Car, under the observation of the A.C.G.B.I.

A.C.G.B.I. Tyre, Lamp, and Speedometer Trials.

THE following is a summary of the performances of the various competing devices during last week—March 5th to 10th—as officially supplied to us :—

Cars.—Dennis car—non stop.

Tyres.—Collier tyres (3 sets)—1 cover replaced owing to bad cut.

Speedometers.—Vulcan, Jones, Gratze and Cowey.—Non stop.

Warner.—Adjustment to driving gear and replacing the shaft.

Lamps.—Worsnop.—Relighting off-side lamp and choked near-side lamp.

Polkey.—Jolted out twice.

Ryta and Hoult (tail lamp).—Non stop.

Metallic Mirrors (tail lamp).—Went out twice.

Worsnop (tail lamp).—Went out three times.

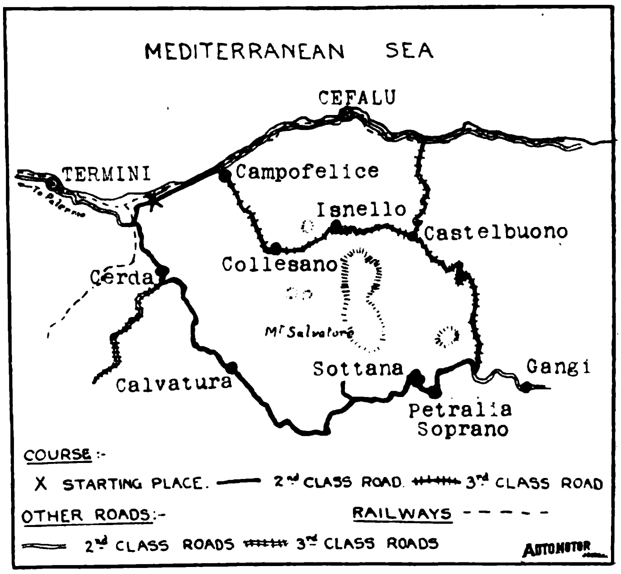
Pradeau Spring Wheel Trials.

AFTER travelling 71 miles, the car on which these wheels were fitted sustained a broken axle. Since then, however, the club report records no mishap, and the test, which started on Tuesday the 6th inst., has been going on successfully. We give a photograph of this set of wheels, fitted to the car on which the trial is being made, as briefly described by us last week. Each wheel has, it will be remembered, a double rim enclosing radial springs which rest in sockets provided for them in the outer ends of the spokes.

A.C.G.B.I. SPEEDOMETER TRIALS.—View of the mileage recorder which is entered in conjunction with the Vulcan Speed Indicator in order to conform with the rules. This instrument is fixed to the wheel-hub.

The Targa Florio.

THIS race in Sicily for tourist cars, costing up to a maximum of £800, promises to be one of the most trying ordeals of the year. Full particulars of the event have already been published in THE AUTOMOTOR JOURNAL, and by way of supplementing these we publish this week some striking photographs taken recently during a journey over the course, together with an outline map of the road selected for the race. Those taking part in the contest will assuredly have a unique experience, and should have many a tale to tell thereafter. That the trial will be a severe one may be gathered from the fact that *none* of the roads selected are classed as "first-class," and more than half are "third-class" roads, these comprising the course through the more mountainous district after leaving Petralia, rising to a height of over 4,500 feet.



Map of the course for the Targa Florio Race in Sicily for Tourist cars, which is to take place on May 6th.

Théry, who has been over the course, does not think it will be possible to average a higher speed in the race than 55 kiloms. per hour, and owing to the unusual severity of the test, it is proposed that the cars shall only cover the circuit twice instead of three times, as originally contemplated. Every effort is being made by the Italian organisers to induce foreign makers to send cars over to participate in the race, for which already a number of the leading Italian makers have entered. Reductions in tariffs are announced in all directions as a tempting bait, these including 60 per cent. off the Italian railways,

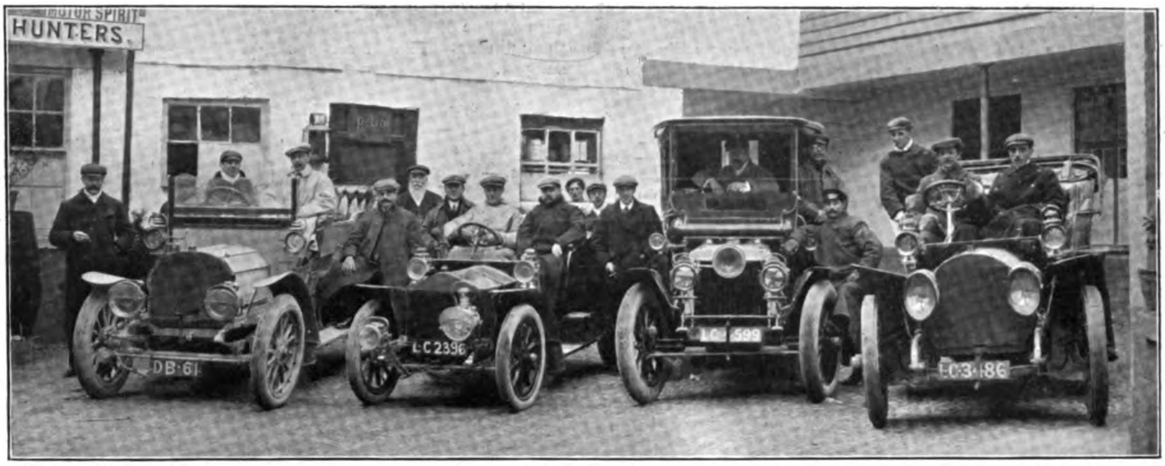


Photo by Argent Archer.

A.C.G.B.I. TYRE, SPEEDOMETER AND LAMP TRIALS.—The cars at Daventry, on the 9th day, including the 24-h.p. Fiat (on the right), fitted with the Pradeau wheels.

75 per cent. off the Sicilian railways, 40 per cent. off the steamboat charges to Sicily (in some cases 75 per cent.), 10 per cent. to 20 per cent. off hotel tariffs, in addition to free admission to all sorts of *fêtes* which are in course of preparation in connection with the event. May 6th is the date selected for the actual race.

Electric Vehicle Trial.

In principle, the A.C. de France have, upon the proposition of the Chambre Syndicale de l'Automobile, adopted a resolution in favour of organising a competition for vehicles propelled by electric accumulators.

Resilient Wheel Trial in France.

The date fixed for the Resilient Wheel Trial in France, organised by *L'Auto*, is April 18–26. The daily stages which the competitors will have to cover total up to 2,128 kiloms., the route selected being from Paris to Nice and back *viâ* Dijon, Valence, and Marseilles.

More French Tests.

Several new contests are proposed by the A.C. de France for touring cars, amongst the most interesting being those for lamp equipments and prevention of smoke from the exhaust.

Nice Speed Events.

After obtaining permission from the authorities to revive the speed races on the Promenade des Anglais, and on the Turbie Hill, it is now stated that the Nice Automobile Club propose abandoning them for this year, owing mainly to lack of entries. The club propose to substitute a Tourist Car Contest.

⊛ ⊛ ⊛ ⊛

MOTOR CYCLING.

International Cup Race (Motor Cycles).

The entries which have now been received for taking part in this race, on behalf of Great Britain, are the two machines by Collier and Sons, the one by C. B. Franklin, and in addition two machines by H. Mogridge, one by T. Silver, and two by A. Westlake. Entries do not close until March 31st. There appears to be a probability of the race itself in Austria being postponed until July 8th.

Motor Bicycle Exhausts.

At last it would appear that a general attack is to be made upon the free exhaust of the motor bicycle. Last week The Automotor Journal welcomed the action of the Auto Cycle Club in taking this very important question in hand, and now we see that the touring commission of the A.C. de France have decided to approach the Prefect of Police, with the object of the authorities taking action against owners of motor bicycles who use their machines with free exhausts, or in which the silencer is ineffective. The suppression of this very grave nuisance will tend very considerably, we think, to eliminate the very widespread prejudice which has been created by free exhaust motor bicycles careering round the country in large numbers.

Motor Cycle Records.

Last week at the Parc des Princes Track, Paris, a triple attack was made on the existing "100 kiloms." and "hour" records by Anzani, Pernette, and Thomas. Anzani and Pernette rode Alcyon machines weighing over and under 50 kilogs., respectively, while Thomas made his trial on a similar make under the one-third litre category. Anzani was unfortunately thrown in his thirteenth round, and so was unable to complete his attempt. His fourth round, however, was made at the rate of 106·5 kiloms. per hour. Pernette lowered Giuppone's record on a Peugeot of 1h. 6m. 36⅖s. for the 100 kiloms. to 1h. 3m. 51⅕s., and accomplished 94·73 kiloms. in the hour, as compared with the 90·360 kiloms. covered by Giuppone. Similarly Thomas lowered Cissac's records (also on a Peugeot) of 1h. 6m. 46⅘s. for the 100 kiloms. to 1h. 5m. 27⅕s., and finished 91·665 kiloms. against Cissac's 89·895 kiloms. in the hour.

The Motor Cycling Club, which last year disputed the right of the Auto Cycle Club to compel other motor cycling clubs in the country to run motor cycling events under a permit from the Auto Cycle Club, and were suspended for their "contempt," have now, we are pleased to learn, come into line with the Auto Cycle Club, and we hope for the future to see nothing but harmony reigning between these two bodies in like manner to the rest of the motor cycling associations throughout the country. The Motor Cycling Club, having acknowledged the authority of the Auto Cycle Club, all the former's events this year will be officially recognised, and already permits have been issued for the leading fixtures which the very energetic Motor Cycling Club have determined to carry through. The suspension of Mr. J. Van Hooydonk has also been removed, and this well-known rider is once more free to take part in events.

The Southern Motor Club inform us that they are now prepared to send entry forms, with gradient and map of district in which Coast Hill, Westcott, near Dorking, is situated, to intending competitors for their Open Hill-Climb for motor cycles and tricars on April 7th next. Application should be made to the Hon. Sec., Sports Committee, 29, Grantham Road, Clapham, S.W.

CORRESPONDENCE.

*** *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion, or containing queries.*

FOUR CYLINDERS *versus* SIX CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I see a suggestion in your issue of March 3rd from a correspondent who wishes to run a 4-cylinder against a 6-cylinder, and the trials which he suggests are as follows:—

1. Horse-power, say 40.
2. Minimum number of revolutions of engine per minute, car standing.
3. Maximum number, ditto.
4. Slow running of car on top gear, clutch not slipping.
5. Fastest speed on the same gear.
6. Ability to take hills on same top gear.
7. Silence when running on top gear.
8. Cars to be of the same total weight; differences to be made up by ballast.
9. Cars to run between two observing cars about 100 yards apart.
10. Petrol consumption to be taken.
11. Engine to run all the time, and not allowed to be switched off running down hill.

Test to be over 100 miles of give-and-take road.

I shall be pleased to run a 6-cylinder Napier car under the conditions set out, and the distance can be made as much greater as the 4-cylinder believer-in likes. I hope we shall see a 4-cylinder advocate come forward and really take the matter up in a scientific way, and let the world see the result.

Yours truly,
March 7th. S. F. EDGE.

BRITISH OUTPUT.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Exception must be taken to the quite unwarrantable remarks and inferences in Mr. S. F. Edge's letter of your last issue. As a looker-on, I wish to ask by what right he appropriates to himself the position of inquisitor upon this, as upon other matters.

As a self-constituted collector of figures that he wishes to be "exceedingly accurate," to presumably benefit the British industry, is it surprising that, with his usual conspicuous tact, he does not find firms complaisantly supplying rival concerns with private information of their business?

In how many instances in other trades are such particulars given, save to disinterested compilers of statistics? He admits two or three firms declined to docilely follow his invitation. Doubtless, to an independent and properly accredited quarter, absolutely free from the reproach of trade interests, the particulars would have been readily given. But because firms choose to exercise their right, it appears to me supremely ridiculous that unworthy deductions should be publicly made and conclusions invidiously come to by Mr. S. F. Edge or other aspirants to erudition.

What I wish to protest against is the general principle of the matter. If Mr. S. F. Edge's requests are not favoured and played up to, by all means let his zeal for the general good suffice for his reward.

The alternative course he adopts is neither new or edifying. Is it, therefore, surprising that the Sir Oracle rôle falls flat? Moreover, with independently compiled figures, no one can retort that self-prominence underlies endeavours however well-meant and characteristic—the assumption of regret and injured innocence notwithstanding. Purity of motive would be unassailable, and I fail to see why Mr. S. F. Edge or anyone else should needlessly lay themselves open to uncharitable rebuffs by those firms who evidently were indifferent to assisting at the desired consummation.

Obviously it is exceedingly doubtful, withal, if such extravagant and impartial contributions as his last will promote good feeling and further those interests he has presumably so much at heart.

Yours faithfully,
NO AXE TO GRIND.
Birmingham, March 12th.

THREE YEARS' GUARANTEE.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I find your correspondent in the last issue makes two misstatements, one in regard to the price of the 6-cylinder Napier, which is £1,050 and not £1,250, and the second in regard to the b.h.p., which is 48 and not 30.

As an owner of a 6-cylinder motor, however, I am afraid I prefer a guarantee of three years to an indefinite guarantee that the bigger the cylinders the better the car, as your correspondent wishes to suggest.

Yours,
March 10th. OWNER.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—With reference to the figures I gave on the question of the three years' guarantee, Mr. Letts, of Messrs. Charles Jarrott and Letts, writes me that the price of the 40-h.p. De Dietrich is £1,000 and not £1,110. My figures were taken from a well-known motor car journal in a list entitled "A Guide to Buyers." On the rectified figures given by Mr. Letts their price per b.h.p. would work out at £19 10s. (or £2 better per h.p., roughly speaking £100 on the total cheaper than I have stated in my letter). Or again, the comparison with Mr. Edge's car would be that Mr. Edge should charge at the same ratio £585, or he is in comparison £665 dearer.

Yours faithfully,
March 9th. D. M. WEIGEL.

[It is evidently not our "Buyers' Guide to the Touring and Pleasure Cars of 1906," to which Mr. Weigel refers above, for in this production (AUTOMOTOR JOURNAL of February 17th, page 195) the 40-h.p. De Dietrich chassis is given as being price £1,000 with 10 ft. wheel base, and £1,040 with 10 ft. 8 in. wheel base.—ED.]

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Referring to your correspondent's letter on this subject in your issue of March 10th, whilst it is exceedingly kind of him to point out that the Napier 6-cylinder will obtain more money than cars of similar horse-power of foreign manufacture, we do not wish credit where it is not deserved, and the price of the standard 40-h.p. 6-cylinder Napier is £1,050 not £1,250, as stated by your correspondent, and the b.h.p. is 48, not 30.

If he would correct these figures his arguments might then be of more utility, and whilst thanking him for his efforts, we feel quite able to put forward points in our own favour without your correspondent, who writes fallacious arguments based on incorrect figures, to prove British motor cars superior to foreign.

We remember your correspondent not so long ago trying to argue that foreign cars were better than British, and we cannot help feeling that the British cause would be better without allies who change so rapidly from pro-Foreign to pro-British.

Yours truly,
S. F. EDGE, LIMITED,
March 9th. H. T. VANE, Secretary.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—With regard to a Mr. D. M. Weigel's letter in your issue of March 10th, I enclose you herewith conversation that I overheard some years hence, following out Mr. Weigel's theories to a logical conclusion:—

Customer: "12-inch stroke, why do you have such a long stroke?"

Salesman: "Oh, it gives you a very much larger 'cubical capacity,' and if you compare our figures with those of our rivals who only have a 10-inch stroke, you will find that our cubical capacity is very much greater in value than theirs."

Customer: "Is this long stroke of any use, or any real test as to the value of the car?"

Salesman: "Not the slightest, Sir, but look what lovely figures it gives as to cubical capacity."

Customer: "Might the engine itself conceivably be better with less cubical capacity?"

Salesman: "Certainly, Sir, but ever since Mr. Weigel laid down the principle of selling and buying cars on their 'cubical capacity,' the increase in the 'capacity' has been enormous, and we are not going to be left behind."

Customer: "Do you give a three years' guarantee with your cars?"

Salesman: "No—but look what a beautiful 'cubical capacity we give!"

Yours truly,
March 12th. J. LAMBERT.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Would you allow me space to ask Mr. Weigel in what way he imagines that the British industry would benefit by Mr. Edge "bringing his prices down to the level of other makers and in proportion thereto."

If Mr. Edge were able to do such a thing, it appears to me that other makers would have to offer an equally attractive car or do no business at all.

Furthermore, it would be interesting to hear why Mr. Weigel does not exploit a "one" or "two-cylinder" car of, say, 50-b.h.p. which would further emphasise his belief in the argument of "Horse Power for Money," which he is putting forward.

Mr. Weigel knows perfectly well, as do all others in the trade who have argued against the 6-cylinder, that, quite apart from price, it is at present the most suitable motor with which to offer such a guarantee, and the sooner its opponents can compete with Mr. Edge, the better for purchaser and industry alike.

Certainly the Napiers are very high in price, but buyers get a good deal more than mere horse-power for their money, and to my mind a standard of excellence is being set, which is the finest example to both British and foreign makers.

For my own part I doubt the wisdom of giving long guarantees, and should expect that such a practice will lead to trouble between seller and buyer.

Yours truly,
ARTHUR BROWN.

Luton, March 13th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I notice a correspondent has given some statistics of what maximum efficiency certain cars may reasonably be expected to give on a basis of cylinder capacity. If his calculations are anywhere near accurate as regards the other cars he mentions, he has conclusively proved the wonderful efficiency of the 6-cylinder Napier, as, although it has by far the smallest cylinder capacity, it gives over 50 per cent. more power for its size than any of the others. I give below the correct figures for the Napier, the rest are those given by your correspondent, arranged in order of cubic capacity :—

Napier ...	300	cubic inches give	48	brake horse-power.
Maudslay ...	380	,, ,, ,,	38	,, ,, ,,
Siddeley ...	430	,, ,, ,,	43	,, ,, ,,
Fiat	450	,, ,, ,,	45	,, ,, ,,
Itala	460	,, ,, ,,	46	,, ,, ,,
De Dietrich ...	510	,, ,, ,,	51	,, ,, ,,
Daimler ...	520	,, ,, ,,	52	,, ,, ,,

No wonder the 6-cylinder Napier cars with such efficiency sell well!

Yours truly,
B. JOHNSON,
Of S. F. Edge, Ltd.

March 10th.

STEAM AND ELECTRIC.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—A note in your issue of the 3rd draws attention to a new periodical which purports to have been born to meet a long felt want of the steam and electric carriage industries, and you, Sir, criticise the necessity.

No one having any acquaintance with your columns would treat your criticisms as journalistic prejudice, but they are, of necessity "editorial." May I, however, as one interested in the electric carriage trade cordially support your protest?

We shall be interested to hear what the manufacturers of steam cars have to say on the matter, but for our part, we see no need for any review to act as a "propelling power," nor do we need a "staff of efficient writers and advisers" to raise the electric vehicle in the estimate of the public. These, to judge by the leading article in the review in question, are its aims.

It is perfectly true that in these days the electric carriage receives but little attention from the automobile Press. It does not, however, take much perspicuity to discover the reason for this.

Two influences make for publicity in the Press—public interest and reciprocity.

There is naturally but little public interest in the technical characteristics and mechanical details of the electric carriage. No amateur drives one because it is much too dull work. There are no cranks and valves and cylinders and change-speed gears for the ordinary man to discuss. Nobody cares twopence whether the electric carriage has one motor or twenty, or whether it carries five accumulators or fifty, consequently we have no pages of correspondence on the subject. It *may* be a matter of doubt whether four cylinders or six promote efficiency, or lessen the innumerable ills which the explosion engine is heir to. So long as the petrol car remains a complicated collection of intricate mechanical parts mounted on a frame and set in motion for the pleasure of men who have a mechanical turn of mind, so long will dissertations on the merits and demerits of cars find a market. The electric carriage has passed out of this stage. It is driven month after month, year after year, by an ordinary professional driver. So ordinary a driver is he, indeed, that he has not even been given a foreign name. There is at present little left to discuss; and, in its own sphere and for its own purpose, it may be said to have reached finality.

You, sir, refer to the days when the electric carriage tried to do wonderful things; tried to be interesting, in fact. In the public interest you devoted many pages to record-breaking runs. Early numbers of THE AUTOMOTOR JOURNAL are full of descriptions of accumulators with wonderful names, and still more startling characteristics. Happily, perhaps, neither the names nor the properties have survived the eliminating trials of time. These days are passed, and so has public interest.

What we have called "reciprocity" may sometimes lead to the mention in the Press of matters not of public interest. This is natural. A newspaper must be run on business lines, and an editor is bound to support those who, by filling his advertisement columns, help his paper to live.

The system may at times be a little crude, and the advertising staff may be injudicious, but they have to live, and even an editor may be excused if he feels less love for those who exist without his help than for those who need his parental care. This again is human, and nobody complains about it. Why should they? The truth is that the electric carriage manufacturer to-day does not require the same kind of advertisement that the makers of petrol cars seek. The number of the former may almost be counted on one hand, whereas who can number the latter?

The London streets give sufficient emphatic publicity to the merits of the electric carriage. They are everywhere. Their very silence is their loudest *reclâme*.

As a manufacturer, I sincerely trust that public interest in technicalities and the necessity for advertising the rival merits of many systems may long be absent from the electric carriage business.

When the time comes, as it must, when one or other of these requirements will arise, we feel sure that the existing automobile Press will treat the subject as liberally in that day as it has in the past.

In conclusion, may we be allowed to say, "Save us from our friends?"

Faithfully yours,
THEODORE G. CHAMBERS,
Managing Director of
THE ELECTROMOBILE COMPANY, LIMITED.

March 12th.

ELECTION MOTOR CARS AND INSURANCE RISKS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—We have all heard of the extent to which candidates at the recent Parliamentary Election benefited by the loan of motor cars, but this new use for the speedy car has had an aspect and a development which have not been previously mentioned, namely, the increased number of accidents and consequential claims under insurance policies. In fact, I have had a calculation made, and for the week from Saturday, the 27th January, to Saturday, the 3rd February, the additional accidents solely due to the election will cost us over £1,500 beyond our normal experience for accidental damage to car and third party claims.

As the cars insured, in the majority of cases, were loaned to friendly candidates who were not the owners, I have no doubt that we could have denied liability for about £1,000 worth of claims, but believing our policy should cover such an use of the car, we have decided to interpret our liability very generously.

Yours faithfully,
FREDK. THORESBY,
General Manager,
Car and General Insurance Corp., Ltd.

Feb. 26th.

MOTOR ENGINEERING PROBLEM.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In the published reports of the paper recently given by Col. Crompton before the Royal United Service Institution there are several statements which can hardly be allowed to pass without scrutiny. For example, the lecturer is reported as having said that "the 2-cylinder engine is now rarely seen even in small cars." Now anyone conversant with the motor industry knows that this is far from being the case. It can with safety be claimed that there is a greater number of 2-cylinder cars on the roads to-day than there are fours, not only so but at no time in the past have cars with this type of engine been turned out in greater numbers. Some of our largest manufacturers devote special attention to cars fitted with this type of engine, and at present one of the largest motor factories in Britain is solely devoted to their production, and such is the demand that a ready market is being found for an output of twenty vehicles a week.

The lecturer goes on to claim that four and even six cylinders are necessary in order to obtain elasticity of drive, even turning movement and durability of rubber tyres. From this the novice would naturally infer that a 2-cylinder car was non-flexible, ran with a series of jerks, and was heavy on its tyres, yet this is not so; 2-cylinder engines, as manufactured by the best engine builders, run with remarkable sweetness, and when fitted with a suitable fly-wheel it would baffle most people to tell after a 50 miles' run whether a 2 or a 4-cylinder engine was below the bonnet. An altogether inflated value seems of late to have been put on "an even turning movement" without due regard being paid to what is meant by the term. What we have to deal with is the effort exerted by the driving-wheels where they touch the ground, and we have to remember that between the drivers and the crank-shaft we have the axles, the differential, the cardan shaft (or the driving chains), the clutch, and the fly-wheel, that each of these is tending to keep the motion of the car steady, either by the energy stored in the moving parts or by the elasticity of the parts under stress, further that the whole mass of the moving car acts to this same end. The engine is giving off an uneven turning effort, it is true, but note the smallness of the time interval during which the fluctuations take place. At the nominal speed of 1,200 revs. per min. we get each complete revolution taking $\frac{1}{20}$ of a second, or a complete cycle in $\frac{1}{10}$ of a second, a period of time too small to permit of the fluctuation of effort from an up-to-date 2-cylinder engine reaching further than the fly-wheel.

Again, it is suggested by Colonel Crompton, that with two cylinders the tyres must suffer. That this is not so can most readily be shown by actual results. The writer knows of several instances of 2-cylinder 10–12-h.p. cars, seated for five persons, and used on ordinary roads, having been run for 5,000 and 6,000 miles on one set of tyres, but cannot recall a single instance of as good results being obtained on a four. Nor is this difficult to account for, because the life of a tyre of a given size is as near as may be, other things being equal, inversely proportional to the horse-power, and is in practice not found to be affected by the number of cylinders.

Having in the first place endeavoured to set aside the 2-cylinder engine, Colonel Crompton next directs attention to the "complexity of parts, costliness of manufacture, and increased risk of stoppage on the road," of the 4 and 6-cylinders, and deplores that English motor engineers are not striving after improvement in the way of greater simplicity and fewness of parts. The Colonel's desire evidently was to pave the way for an advocacy of the steam car, but it seems to the writer his arguments are far more telling on behalf of the properly designed and built 2-cylinder car. In this you have the great simplicity asked and the minimum number of parts to give trouble or to need adjustment, and at a moderate cost. The upkeep of such a car is very low, and for ordinary running need not exceed £50 a year, while such a car can be bought from £350 to £400, with any style of body desired. For the man of moderate means who wishes to keep his car for general use, and who wishes to have the maximum of pleasure with the minimum of worry and expense, the well-made 2-cylinder petrol car takes a lot of beating. Of course, for the man to whom money is no object, the 4-cylinder, high-powered car is essential, but the number of such persons must always be small compared with the thousands to whom the lower-priced, simple, reliable, and efficient 2-cylinder appeals.

Yours, &c.,

Glasgow, March 12th. L. J. A.

THE GLASGOW SHOW.

FOUR years ago I had the privilege of describing in these columns the last motor car-show held in Glasgow, and then ventured to suggest that as the accommodation in Burnbank Drill Hill was much too limited, the promoters would do well to take the East End Exhibition Buildings for the next display. But the organisers of that event went out of business, and it was not until Mr. Walter Cawood came along and beheld the value of the West of Scotland Market that the suggestion came to be carried into effect. Unfortunately the building, although of ample dimensions, is a little out of the way, besides having some structural defects, but neither shortcoming will keep the crowd away, and although it is a little too early at the time of writing (Monday) to prophesy with any degree of assurance, the indications are all in favour of good business being transacted.

The show of cars is wonderfully good and representative, the display of foreign cars especially being remarkable for a provincial exhibition. The arrangement of the stands is rather defective, no attempt having apparently been made to keep the various exhibits of a kind together when space was being let. The result is that some of the best stands are in the hands of metal polish, typewriter firms, and such like. This defect will no doubt be remedied when another show comes along.

About a hundred pleasure cars are on view, of which over fifty are all British, over forty all foreign, and about half a dozen British frames and running gear with foreign engines, or *vice versa*. The Argyll comes first among the British cars in point of numbers, but there are more Darracqs shown than any other make. Most of the Argylls are on the stand of the manufacturers, the others on that of their Glasgow agents, the Western Motor Company, while the Kennedy Motor Company—the Scottish agents for Darracqs—show eleven cars of that make out of the sixteen in the Show. There are eight Arrol-Johnston cars of various types on view, including one of their original dog-carts and the Tourist Trophy winner. Siddeleys come next in number, six cars being on view between the Wolseley Company's stand and that of Rennie and Prosser. Three Wolseley cars are also shown on the Birmingham makers' own stand. A new car to Scotland is the Bell, made by a Yorkshire firm of that name, who show four cars, a number equalled by the Albion cars on the stand of the manufacturing firm of that name. The last-named have also working models of their patent magneto and governor on view. The Rossleigh Company show three Daimlers, two Peugeots, a Darracq, and a Humber. Besides the Siddeley mentioned, Rennie and Prosser show two Panhards of 15-20-h.p., a 35-h.p. Mercedes, and a 40-h.p. Napier chassis.

The Peacock Autocar Company have a couple of 15-20-h.p. Chenard and Walcker machines on view, and another of the make is shown by a Paisley carriage-building firm, McGeoch and Co., fitted with a body of their own make. Another Company of this kind, John Croall and Sons, of Edinburgh, show a couple of De Dietrich cars and a Mercedes, one of the first, and the latter having bodies of aluminium of the firm's own construction. Two of the most handsome cars in the Show are a couple of Delaunay-Bellevilles on the stand of the Western Motor Company, of Glasgow.

Other British, or partly British, cars not already mentioned, are two Humbers, two Kelvins, two St. Vincents, a Crossley, a Holloway, and a Ridley. Other foreign cars are a couple of Clements, and an equal number of Asters (chassis), Spykers, Minervas, Vinots, a Martini, and a Germain.

I noticed eight tricars of seven different makes, one, the Holloway, being of local make. Over twenty motor cycles are shown, the majority being foreign made.

Heavy lurries and road waggons are shown by Morton, of Wishaw, Stewart, and the Glasgow Motor Lorry Company of Glasgow, the Yorkshire Company of Leeds, Coulthard of Preston, and Robertson of Fleetwood. Ten of these machines are on view, all fitted with steam engines. Light industrial vehicles are still few in number, about half-a-dozen all told covering the lot, and three of them are Argylls, two delivery vans, and a commercial traveller's sample carrier, fitted with shelves and seated for two inside. There is probably a better display of boats than usually seen in provincial shows, nine being on view, ranging from a 12-ft. 2-h.p. dinghy to a 30-ft. 12-h.p. cruiser, having a comfortable-looking little cabin forward. This boat, with a 12-h.p. 2-cylinder Brooke motor, is finely built and appears cheap at £275, the price asked. Besides the boats, there are about a score of boat motors, both two and four-cycle, besides propellers, reversing and other gear. Tyre companies present include: Shrewsbury and Challiner, the Samson Non-Skid firm, and Pullmans, of Godalming.

The exhibition was opened on the forenoon of Friday, the 9th inst., by the Marquis of Graham in the presence of a distinguished company. The band of the 1st Life Guards give performances twice each day, a big attraction to many who are not motorists.

A. F. S.

The "Motor School" Case.

THE trial of Riska Medawar and John Raymond Kerr was concluded at the Central Criminal Court on Monday last, and resulted in the acquittal of both the accused.

Mr. Emmanuel Victor, an architect, in giving evidence on behalf of the accused, stated that he was a practical motorist, and in his opinion the premises occupied by the prisoners as a garage were reasonably fitted up for the purpose of teaching pupils to drive motor cars. As in any other business, the art of driving a car depended very much upon the intelligence of the person who drove. He had no doubt that if a pupil possessed the necessary intelligence, and a determination to learn to drive, he might have done well at this garage.

Witness said a friend and himself purchased a car, and started off on their own account. If anything went wrong they had to find out what it was, and put it right.

Mr. Leycester: And you survived?

Witness: Oh, yes.

Medawar went into the witness-box, and swore as to the genuineness of the undertaking, and at the conclusion of his evidence the Common Serjeant held that there was no case to go to the jury.

Both the accused were accordingly acquitted and discharged.

AERONAUTICS.

To the Pole by Balloon.

THE Wellman Polar navigable balloon is approaching completion, and we are now able to supply some further particulars in regard to its appearance and arrangement. The general outline of the balloon is rather like Santos Dumont's No. 9, that is to say, the gas-vessel is a great deal larger towards the front than the rear; and it cubes no less than 6,300 metres. The method of suspension of the hull or car from a flap of the material which constitutes the gas-vessel, is also similar to the Santos Dumont construction, but the hull itself is relatively shorter than most of M. Santos Dumont's navigable balloons, in this respect more resembling the Lebaudy design, and carries a propeller at either end. The manner in which the rudder is mounted at the end of a vertical plane, and the existence of a flat stability plane close under the gas-vessel, also remind one of the Lebaudy airship. In fact, the machine may be roughly described as constituting a cross between Santos Dumont's No. 9 and the earlier type of Lebaudy. The gas-vessel is also constructed on somewhat similar principles to those of the Lebaudy airship, and consists of two layers of pure Para rubber with two layers of cotton interspersed between them. It is intended to make special use of the guide-rope, and in addition to the oil, petrol, and other stores that will be required, the vessel is to carry a small light sheet-steel boat.

Amongst those who it is now announced will take part in the expedition, are the French aeronaut, M. Gustave Hervieu, who has had great experience in ballooning. We have already given particulars of the arrangement of the motors, in accordance with which a 50-h.p. main motor will provide the principal driving power, being assisted when necessary by an auxiliary motor of 25-h.p., which, however, is alone capable of driving the airship.

Three weeks will be spent at Spitzbergen in preliminary experiments, and if they all turn out successful a start will be made at once. There seems no doubt that the explorer really intends making a start, and we trust that his experiences will be more fortunate than those of the Swedish explorer, Andrée, who attempted to solve the problem with a spherical balloon.

Shanks' Flying-Machine.

AMONGST those who claim to have "solved" the problem of aerial navigation, must apparently be included one Mr. James Shanks, of Clapham Park, formerly a boot-maker, and now an auxiliary postman. We understand that his proposed machine is of the flapping wing type, though it does not appear that Mr. Shanks has ever actually constructed one. In order to raise the money to rise in the air, he has brought out a sort of flying machine merry-go-round, which it is stated gives great pleasure to those who entrust themselves to its vagaries. At any rate, there is no propulsion by gas engine, but each passenger appears to supply his own motive power by working treadles. It is stated that Mr. Shanks has employed his leisure moments for forty years in studying aeronautics, but it is difficult to estimate to what the leisure moments of an auxiliary postman, even if extended over a period of forty years, would altogether amount to, and certainly aeronautics does not strike one as providing problems which can be successfully tackled by anybody merely in his leisure moments.

The Emperor William and Navigable Balloons.

EMPEROR WILLIAM has evidently been profoundly impressed by the performances of the Lebaudy airship, and by the fact that it has been bought up by the French Government for military purposes. It is stated that he intends to nominate an Imperial Commission to study the subject scientifically, as His Majesty is firmly convinced that airships of this type are capable of rendering the most valuable services in case of war.

A New Gillespie Model.

FROM the United States come rumours of a new Gillespie model airship, which, from all we can understand about it, consists of a hollow pyramidal structure of the thinnest aluminium plate, externally stayed, which forms the gas-vessel. It is fitted with propellers on either side, driven by a spring motor, and experiments with it are, as usual, said to have been satisfactory. The inventor seems to have some sort of idea of combining the advantages of an airship with an aeroplane, as the pyramidal aluminium gas-vessel is fitted with side aeroplanes. But somehow one does not expect much success from any attempts to combine totally different methods of solving the same problem.

The Gordon-Bennett (Aeronautical) Cup.

THE Aero Club of the U.K. have provisionally selected Professor Huntington, of King's College, Mr. Frank Butler, and the Hon. C. S. Rolls, to compete as the representatives of Great Britain in the "race" for the Gordon-Bennett (Aeronautical) Cup. The other competing countries have selected their teams as follows:—

Germany.—Baron von Hewald and Herr "Hugo."

Belgium.—M. Van der Driesche.

Spain.—Senor J. F. Duro, Captain Kindelau, and Don Esteban Gutteriez de Salamanca.

America.—Mr. Frank S. Lahn and M. Santos-Dumont.

Italy.—Signor Alfredo Vonwiller.

The race, as announced in THE AUTOMOTOR JOURNAL last week, has been fixed to start from the Tuileries Gardens, Paris, on September 30th.

French Military Aeronauts.

THE French Army is carrying out and further extending the training of an aeronautical department, which is more and more becoming a regular and important arm of the service. Candidates for this branch must above all things have keen vision, but what may not be quite as satisfactory to them, they should also be as light and airy as possible, so that no Daniel Lamberts need apply.

* * * *

The Sultan of Johore's 120-h.p. Mercedes.

FOLLOWING his previous purchases of Mercedes cars, we now learn that the Sultan of Johore has acquired from Messrs. J. E. Hutton one of the latest 120-h.p. racers that have been built for this season. The general appearance of this vehicle was shown in our issue of February 17th, where on page 213 we illustrated "Three Generations" of this celebrated make of racer.

THE TARGA FLORIO RACE IN SICILY.—A scene on the Sicilian Circuit on the approach to Isnello, showing a native stage coach drawn by mules.

CLUBS AND ASSOCIATIONS.

Automobile Club of Great Britain and Ireland.

THE Annual General Meeting of the club was held on Thursday, last week, at 119, Piccadilly. Amongst those present were the Hon. Arthur Stanley, M.P., Chairman of the club, who presided, Lord Montagu of Beaulieu, Sir Boverton Redwood, D.Sc., Mr. Robert Todd, Mr. Roger W. Wallace, K.C. A highly satisfactory report and balance sheet for the past year were presented to the members, showing that the club is still continuing its successful career both as a society of encouragement and as a social organisation. In the course of his remarks on the report the chairman referred to the growing membership of the club, which now numbers over 2,800 members, and to the large amount of useful work achieved in many directions during the year, more particularly as regards the institution of examinations for driving and mechanical proficiency certificates, the collection of evidence for the Royal Commission on Motor Car Traffic, touring at home and abroad, and the institution of the International Tourist Trophy Race for the evolution of the best type of motor vehicle. He congratulated the club on its work in connection with the prevention of inconsiderate driving, complaints in regard to which had greatly diminished. He also referred to the growing popularity of motor traction, as evidenced by the increasing number of public motor vehicles in London and the provinces.

The committee for the ensuing year is constituted as follows:—Members elected by ballot on Thursday:—Hon. Arthur Stanley, M.P., Lord Montagu of Beaulieu, Mr. Lionel de Rothschild, Mr. Charles Hardy, Major F. Lindsay Lloyd, R E., Mr. Wilson Noble, Mr. E. H. Cozens-Hardy, Lieut.-Col. R. E. B. Crompton, C.B., Mr. Stanley Spooner, Mr. Alfred F. Bird, Mr. E. Manville, Mr. J. R. Nisbet, Dr. H. S. Hele-Shaw, F.R.S., Mr. M. O'Gorman, Dr. Bruce Porter, Captain Dyke Acland, Mr. T. G. Chambers, Mr. T. H. D. Berridge, M.P., Mr. J. D. Siddeley, Mr. James F. Ochs, Mr. Claude Watney, Mr. E. M. C. Instone, Mr. Alfred Armitage, Mr. Henry Sturmey, Dr. J. Hopkins Walters.

Non-retiring Members this year.—Mr. F. P. Armstrong, Mr. W. Worby Beaumont, Hon. Stuart Bouverie, Professor C. V. Boys, F.R.S., Sir W. J. Bull, M.P., Mr. F. H Butler, Capt. H. H. P. Deasy, Mr. Henry Edmunds, Mr. J. M. Gorham, Col. H. C. L. Holden, R.A., F.R.S., Mr. J. A. Holder, Mr. Vere Ker-Seymer, Mr. W. J. Leonard, Mr. G. Montagu, Mr. Henry Norman, M.P., Mr. Robert E. Phillips, Sir Boverton Redwood, D.Sc., Hon. C. S. Rolls, Mr. C. D. Rose, M.P., Earl Russell, Mr. J. Lyons Sampson, Capt. G. H. J. Skeffington-Smyth, D.S.O., Mr. Sidney Straker, Mr. F. Strickland, Mr. Robert Todd.

Aero Club.

THE second monthly dinner of the Aero Club was held on March 6th at the Florence Restaurant. The dinner was well attended, amongst those present being Mr. R. W. Wallace, K.C. (chairman of the club), Mr. Frank Butler, the Hon. C. S. Rolls, Professor Huntington, of King's College. Mr. and Mrs. Griffiths Brewer (the first lady to cross the Channel in a balloon), Mr. J. Moore-Brabazon, Mr. Martin Dale, Mr. Ernest Bucknall, and Mr. Warwick J. Wright.

H.S.H. Prince Blucher, His Grace the Duke of Sutherland, and the Hon. Arthur Stanley have been elected to the Council of the Aero Club of the United Kingdom.

British Empire Motor Trades Alliance, Limited.

THE following firms have recently been elected to membership:—Messrs. Grice and Harrison; Howes and Burley, Ltd.; Rubery, Owen, and Co.; Joseph Sankey and Sons, Ltd.: Scott, Stirling, and Co., Ltd.; Scottish Motor Eng. Co., Ltd.; William Stephens and Co.; S. Stevenson and Co.; C. A. Vandervell and Co.

Hertfordshire County A.C.

A BIG gathering of members and their friends attended the reception given by this club at Watford on the 8th instant, the occasion being to celebrate the amalgamation which we recently announced. Mr. Basil Crump during the evening gave a lecture, selecting as his subject "Motoring at Home and Abroad," which proved to be a graphic and interesting account of motoring in England, Holland, Germany, Switzerland, Ireland, and India, a series of lantern slides accompanying the lecture. A pleasant little interlude was the presentation to Mr. T. Williams, the hon. secretary of the West Herts Motor Club, which is now merged in the Herts County Club, with a silver cigarette case, as a mark of appreciation of his services for the past season.

Amongst the fixtures already arranged for the coming season, the principal ones are announced to be an Open Motor Cycle Hill Climb at Maple Hill on April 21st, and an Open Car Hill Climb at Aston Hill on June 30th. The opening run takes place on April 7th, at Hatfield.

Nottinghamshire A.C.

On Friday of last week, Mr. Arthur Hirst read a Paper on "The History of the Simms-Bosch Magneto," before the club, in the course of which he mentioned that Mr. F. R. Simms first devoted his serious attention to the employment of magnetos, for the ignition of petrol engines, in 1896, and that it was in 1897–98 that Mr. Simms and a Mr. Bosch (of Stuttgart), had sufficiently developed their machine to place it upon the market. The paper was well illustrated throughout, and much interesting information was given concerning the construction, manipulation, and merits of this very useful type of ignition mechanism.

The Society of Motor Manufacturers and Traders.

The Annual General Meeting of the Society of Motor Manufacturers and Traders will be held at 3 o'clock on Thursday afternoon, the 22nd inst., at Maxwell House, Arundel Street, Strand. The result of the postal ballot for the election of the Council will be announced. The report, accounts, and balance sheet will be submitted. These will show a satisfactory result of the year's work, and a considerable increase in the reserve fund. The formation and work of the various sections—the commercial vehicle, marine, motor tyre and accessories, and carriage builders—will also be detailed.

A general meeting of the Society of Automobile Mechanic Drivers will be held at 51, Brick Street, W., on Tuesday, March 20th.

"Motor Services in Relation to Tramways."

The above is the title of a paper to be read before the Tramways and Light Railways Association on March 27th, at the Lecture Room, Society of Arts, by Mr. Norman D. Macdonald, Advocate (Member), the Hon. Arthur Stanley, M.P. (President), in the chair, 8 p.m.

"Lubrication."

Mr. J. W. G. Brooker has arranged to read a paper at the Auto Cycle Club upon the above interesting and important subject.

COMMERCIAL POINTS.

Omnibus Non-Stop Run.

One of the new 30–40-h.p. Maudslay 'buses which are being supplied to the Scottish Motor Traction Company, recently accomplished a non-stop engine run between Coventry and Edinburgh. Six passengers were carried, and very heavy weather was experienced during the latter part of the journey, which occupied about 25½ hours, including halts for refreshment.

Dunlop tyres again topped the list numerically at the Manchester Motor Show, 164 Dunlops being fitted to exhibition cars.

Amongst the recent purchasers of Daimler cars are H.I.M. the King of Siam, Lord Radnor, and Lord Harlech.

Mr. James Ward, Managing Director of the Northern Quarries Company, Ltd., has just secured a new 20-h.p. Rolls-Royce car, which he intends to use for the purpose of touring the whole country in connection with the new system of road-making, introduced by his Company, which is said to be perfectly dustless.

The formal opening of Messrs. Frank Little and Co.'s new motor depôt and showrooms at 19–21, Westgate Road, Newcastle-on-Tyne, took place last week, when the Mayor of Newcastle, Alderman J. Baxter Ellis, honoured the firm by his presence and support, and referred to the enterprise of Mr. Little and the good he was doing for the city by establishing such a fine garage and important place of business.

At the next general meeting of the Continental Caoutchouc and Guttapercha Company, we are informed, a dividend of 40 per cent. will be declared, as against 33⅓ per cent. in 1905. The turnover during the past year has been far in excess of all previous records, and the turnover for January and February this year also shows a great increase over that of the same period in 1905. Prospects are again very satisfactory, especially with regard to the English business, the turnover of which during the first two months of this year being treble that of the first two months of 1905.

THE TARGA FLORIO RACE IN SICILY.—Some of the natives who are interested in the advent of the motor car (seen on the left) in their midst. The scene is in Caltavuturo.

PNEUMATIC TYRES FOR MOTOR VEHICLES.

THEIR SELECTION, MANAGEMENT, REPAIR, AND MANUFACTURE.

By COLIN R. CROMBIE.—(*Continued from page* 297).

How to carry "Spares."

EVERY driver carries one or more spare tubes. This precaution is necessary, as without spare tubes one is compelled to repair any damage on the road in all weathers, or drive his car home on a deflated tyre, which is an expensive habit, as it usually ruins the tyres. With a spare tube, such risks are avoided, but care must be taken how they are carried, as they are easily damaged. Many drivers keep their spare tubes in the tool box, which is the worst place in which they can be kept, as the moving tools, when the car is in motion, rub holes in them. All spare tubes should be carried in a waterproof bag made for the purpose, as this keeps them from being chafed, and from contact with oil and grease. Spare outer covers should also be carried in special waterproof cases which are made for the purpose. This protects them from the sun's rays and from wet. Care should be taken to attach them firmly to the car, so that they do not get chafed by moving about.

Merits and Demerits of Solid Rubber Tyres.

There is, and I suppose will continue to be for a long time, especially among the recent additions to the ranks of motorists, a good demand for solid tyres. Apart from the unpleasantness of repairing punctures on the road, the matter of expense has often to be considered and the cost of tyre renewals seriously weighed against the advantages of the pneumatic tyre. I think you will find, in the long run, that the pneumatic tyre is the cheapest. The solid tyre may outlast four pneumatics; but, again, the solid tyre will probably wear out four engines, while the pneumatic is keeping one in good condition. Sooner or later the vibration set up with the solid tyre will have its effect in crystallising the metal in the parts chiefly affected by the vibration. I think it will be found more satisfactory to incur the expense of renewing a worn-out tyre than to run the risk of repeated machinery repairs and renewals. The only way to reduce the tendency to crystallisation is to make the parts enormously strong, and I think that in the designing of cars there is an increasing tendency to keep down weight as much as possible.

Chiefly a Matter of Speed.

In comparing the relative merits of the pneumatic and solid tyres as above, I have been referring chiefly to cars which are run at a high speed. As a matter of course, where high speed is not required, and vibration is consequently very much reduced, solid tyres are more suitable and may serve the required purpose, while they certainly save a very substantial amount of expense and trouble.

Fair Wear and Tear of Pneumatics.

Just a few remarks with regard to the ordinary wear of the rubber treads. Everything, even the hardest diamond, wears out, and the time comes when the article becomes unfit for further use and has to be replaced. Sooner or later the rubber tread becomes worn through—sooner on the high power cars than on the small ones—and the canvas, which is the real support of the tyre is laid bare. This must be so, owing to the constant friction of the tyre, against the ground. One would suppose this was evident to most people, but there are some who attribute it to the bad quality of the tyre. All the standard makes of tyres do not contain the same "mixing," but that mixing which each manufacturer thinks is the best, and it is one of the principal points in the manufacture of a tyre to find a mixing for the treads that will stand constant friction without cutting or splitting.

A Stitch in Time.

No one should go on using a tyre after having worn the tread down to the canvas, but it should be sent at once for retreading. In many cases, if a tyre is taken in time and is sound at the bead, it will perform practically the same work as a new tyre. I have seen retreaded tyres run 5,000 miles and more, and I have also seen new tyres worn out in less than 500 miles, under similar circumstances. All makes of tyres are, of course, not equally good.

Roadside Cuts and Punctures.

On all country roads are found the enemies of the pneumatic tyre, such as nails, broken glass, sharp stones, &c., which cut through the treads. The damage caused by these may be of two different natures; only the outer cover may be torn or cut to a greater or less depth, or both cover and inner tube may be cut right through, the tyre being rendered, for the time, useless.

Repairing Minor Damages.

Assuming that only a small nail, or other pointed object, has cut into the tyre, not deep enough to damage the inner tube, the driver can go on for the moment without troubling about repairing it. On reaching home, however, he should clean out the wound thoroughly with petrol and a pointed piece of wood, removing all sand and other grit. He should then apply a good coating of rubber solution, forcing it into the wound with a stick, allowing it to dry until "tacky"—that is, until it clings to the fingers when touched. When the solution is sufficiently dried, the hole should be thoroughly plugged with "Grippa" tyre amalgam sold for the purpose, and this should be thoroughly bound down till quite dry. Only the very best quality of solution should be used for this purpose.

More Serious Cuts and Bursts.

It is, of course, quite a different matter when one or more of the canvas layers is cut. In that case, water, sand and grit are forced into the hole and between the plies of canvas and rubber, blistering the latter and gradually enlarging the hole until the tyre bursts. Such covers can only be repaired in a proper factory. In the case of deep cuts and bursts, the tyre has to be built up again at the damaged part by a special process known as "Stepping."

"Stepping."

This consists in removing a portion of each of the three or four layers of canvas of which the casing is composed, commencing with the inside lining of the cover and reducing the size of the portion removed from each succeeding layer, the smallest portion being taken from the outer layer. The portions removed are then replaced with fresh canvas. This is the only really effective way of repairing such a damage, and I may say that, since this process was introduced by my firm, large numbers of tyres which were considered useless have been made quite sound again, and will out-last the remainder of the tyre.

Useless Patching.

I have seen a large number of similar damages repaired by means of an ordinary two-ply patch stuck over the hole. This is worse than useless, as such a patch has insufficient strength to resist the air pressure, and is forced outwards into the hole, where it is gradually bitten through.

Temporary Repairs on the Road.

When both the other cover and the inner tube have been pierced, the best way to proceed in making a temporary roadside repair is as follows:—The first thing to be done is to detach the outer cover, remove the inner tube, and locate the puncture in the usual way. After having found the hole, take a piece of glass paper, or better still, a small rasp (what is known as a shoemaker's rasp is the very best thing to carry for this work), lay the tube over a block of wood or other suitable surface, and rasp the rubber round the damage until it is quite rough. This gives the solution something to hold to. Unless the surfaces, both of the patch and the tube, are thoroughly roughened, the patch can never be made to adhere properly. Cover well and evenly the patch and the rough portion of the tube round the puncture with two or three coats of solution, and allow each coat to dry until "tacky." This is very necessary, as if the solution is not quite dry the patch will not adhere properly, and will curl up at the edges. Then lay the patch evenly on the puncture, seeing that it does not crease, and press it down firmly. Rub some French chalk over it, so as to prevent any surplus solution from sticking to the cover. If it is only a thin nail that has punctured the cover, it will be sufficient to place a small piece of solutioned canvas over the hole on the inside of the cover. To do this, clean away all the French chalk that is sticking to the cover with petrol, solution both the patch and cover, allowing them to dry before sticking the patch down.

"Plasters" for Large Holes.

Should, however, the damage be a large one, then a different repair will be necessary, and what is known as a "plaster" should be used. A plaster is made up of three or four plies of canvas, each ply smaller than the one beneath it, thus giving a stepping, the various plies of canvas being vulcanised together. This forms a stiff patch, and effectually prevents the tube from being blown through the hole in the cover.

"Plasters" only Temporary, However.

A plaster can, however, only be considered a temporary repair, and the cover should, as soon as possible, be sent to the factory to be permanently repaired. The plaster above described is, of course, cemented to the inside of the cover in the same way as an ordinary patch. If the hole be a large one on the outside, then it will be necessary to put on a gaiter, as otherwise sand and water will get into the interior of the tyre, and thus make the permanent repair more costly.

The Legitimate Functions of a Tyre.

I am disposed to think that the functions which a tyre is required to perform are becoming too numerous. If the tyre-maker heaps on his tyres duties which they were not originally intended to perform, he will be in danger of forgetting what are the principal functions of a tyre. The result will be that, though the tyres may be proof against side-slip, puncture, &c., they will lack resilience, or have a very short life. Nothing is perfect in this world, and the pneumatic tyre has its limits of use. As at present constructed, it is an admirable absorbent of vibration, and can stand a vast amount of wear, but there is no reason why it should be forced to assume properties which are really foreign to it.

Skidding.

Take, for instance, the question of skidding, especially noticeable at this time of the year. Some tyres are more liable to skid than others. To alter the tyre with a view to reducing skidding, as far as possible, has been shown by experiment to tend towards seriously reducing both its resiliency and its wearing qualities. The liability to side-slip is, I think, in many cases, due to the design of the car, or the bad adjustment of brakes, and to make the tyre suffer for this is a mistake. How is it that some cars are more liable to side-slip than others? There is considerable divergence of opinion as to whether round treads or square treads have the least inclination to side-slip. Some say the round tread is the best, because it forces the mud away on both sides, and so gets a grip of the solid road, whereas the square tread traps the mud underneath it. In the same way, of course, the round tread will have a tendency to displace nails, stones, &c. Apart from the application of metal studs, chains, &c., as a preventative of side-slipping, I am inclined to think that the best results would be obtained from round treads having on their face one or more grooves of sufficient depth.

Non-Skid Devices.

The question of non-skids demands close attention until a satisfactory non-slipper and protector has been found. A considerable advance in this direction has recently been made, but I think you will admit that such appliances are still far from satisfactory, and it is hard to tell in which direction ultimate success will be attained. As a protector to the treads, the non-skidding bands now in use are far from being perfect. In my opinion, the great objection to these is that they separate from the tread when running, and thus set up a friction with the rubber of the tread. You may have noticed that when a non-skid of this description has been fitted to a tyre for a few weeks, swelling begins to appear at the sides of the cover. This is caused by the friction on the sides on the tread grinding the rubber into a fine dust. This dust must find an outlet, which it does along the sides of the tyre. The studs keep pounding away until they cut through the canvas, ultimately causing the tyre to burst. No doubt non-skids of this description are of great use as a preventative of side-slip, and thus often prevent serious damage.

Detrimental to the Tyres.

On the other hand, however, there is not the least doubt that any advantage gained in this direction is to a large extent counteracted by the damage which is undoubtedly done to the tyres by their use. Judging from my experience of the condition in which such tyres are when sent to us for repair, I do not hesitate to say that more damage is done in such tyres by these bands than would be possible had the naked tyres received careful usage over average roads for some time. It therefore seems to me that the most satisfactory form of non-skid is a detachable one, which can be temporarily applied to the tyre when the state of the roads necessitates its use.

Spring Wheels.

I am frequently asked if there is any prospect of the pneumatic tyre being superseded by some form of spring wheel. To such a question it is extremely difficult to give an answer. Up to the present time a vast amount of ingenuity and no little money has been expended in experimental work, and apparently to very little purpose. A tyre formed from steel springs is no doubt absolutely proof against puncture, but, on the other hand, is liable to breakage at any time and obviously difficult to repair.

Can Steel Stand Like Rubber?

Everyone who is acquainted with the nature of steel and the action of a spring knows that the finest temper is not absolutely proof against breakage, and that after the springs have been flexed and returned to their normal position a certain number of times, they are liable to fracture at any moment. That they will ever be produced with a resiliency at all equal to that of a pneumatic tyre is, I think, not to be expected.

Future Prospects of Pneumatics.

Then there are other appliances, such as pneumatic hubs, spring spokes, and so on, which seem scarcely worthy of consideration, as they are not tyres at all, but merely ingenious, and probably very effective, forms of spring. Pneumatic tyres have now reached such a stage of perfection that they can be relied upon to run many thousands of miles. They are yearly being improved, and a few years hence will probably be very much better than they are at the present time.

(*To be concluded.*)

⊛ ⊛ ⊛ ⊛

Conversion of the L.C.C.

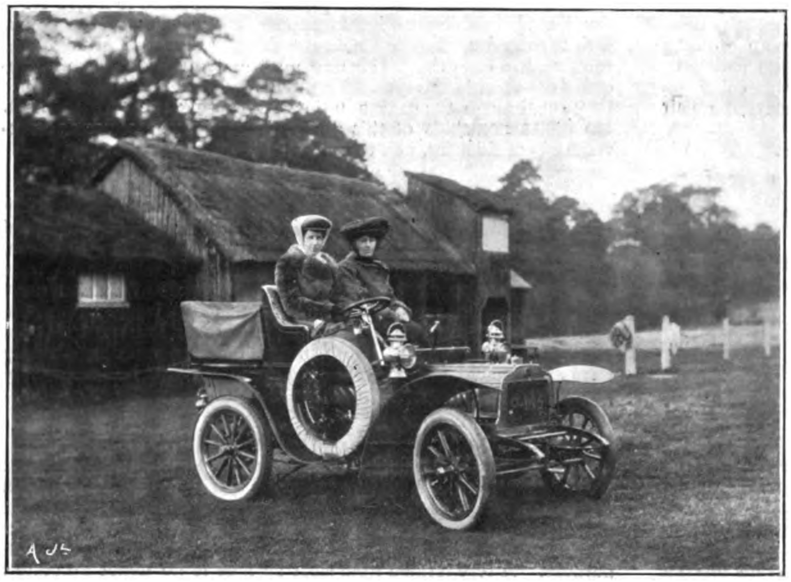
THOUGH the London County Council have hitherto been deaf or blind to the advantages of the motor 'bus, and have devoted all their backing to the electric tram, it is plain that they are not altogether insensible to the advantages of the automobile in a more restricted sphere, as it appears from the information recently issued to the public that the Council are being recommended by their Establishment Committee to purchase *two* motor cars, one for the Engineer's Department and one for the Architect's Department. In the meantime they are to hire cars for the use of committees and of heads of departments. Perhaps really after all the County Council have no inherent objection to automobilism, and mayhap when once all the electric trams at present contemplated have been put down, will become more friendly to the motor 'bus.

Too Late for Prevention.

IN the meantime, the colossal character of their expenditure on tramways has excited much general indignation in various circles, and Mr. N. Woodward, at the General Meeting of the Surveyors' Institute, on Monday last, suggested that Parliament should pass an Act to prevent the enormous outlay on tramways which the London County Council are contemplating. We fear there is not much chance of that Act being passed, as probably most of the contracts are already signed, but if the County Council attempt to add further to the tramification of London, we certainly trust that any such attempts will be opposed in the most determined manner possible.

A Novel Grievance.

THE drivers and conductors of motor 'buses have been congratulating themselves on the much shorter hours which prevail in that profession than are customary in connection with the old-fashioned horse-pulled 'buses. Everything in this world, however, appears to have its compensations or corresponding disadvantages, and the conductors declare that the large number of fares they have to collect, the peculiar motion of the motor 'bus, and their frequent excursions to the top and along the top of their vehicles, has the effect of prodigiously increasing their appetites, so that although their wages are higher than those of horse 'bus conductors, they actually have less money to spend owing to the increased amount which they consume in eatables. Some people are never happy. One is reminded of the farmers who one very favourable year complained that the turnips were growing so big they would soon be unable to boil them.



Many people are surprised at the number of lady automobilists who are now constantly seen driving their own cars both in town and country. There are many chauffeuses, however, who go beyond merely driving their cars; they also take a great pride in looking after them in every respect, making adjustments, and even to cleaning their vehicles. Miss Hotham must be included in this category, being, moreover, a self-taught motorist, never having had a chauffeur. Miss Hotham, who is seen in our photograph at the wheel of her Georges-Richard car, plays golf for Surrey and Woking. Her companion is Miss Lily Mott, who is also known in the world of sport.

The Royal Tour in South Africa.

THERE has been no little discussion at various times as to the suitability of the standard types of pleasure vehicles for use in South Africa, so that it is interesting to find that their Royal Highnesses the Duke and Duchess of Connaught patronised this form of locomotion during their visit to Bloemfontein. A 6-cylinder Napier having been placed at their disposal by Mr. C. Newberry, their Royal Highnesses were enabled to make a much more extended inspection of the surrounding country and places of interest in the short time available than would otherwise have been possible.

More Police Illegality.

THE police are so very fond of issuing several summonses constituting different charges in reference to one and the same occurrence, that it cannot perhaps be too generally known that this procedure is quite illegal and opposed to the principles of English common law. A case of the kind, which is interesting, as the Bench recognised this illegality, was heard before the Petersfield County Bench on the 7th instant. Mr. Charles Hoffer was summoned for not stopping his car when requested to do so, in Dragon Street, Petersfield, for driving negligently in the said Dragon Street, and for driving a motor car at a speed dangerous, &c., also in Dragon Street, the occasion being, of course, one and the same throughout. The first summons was dismissed by the Bench, whereupon counsel for the police proposed to proceed with the other two summonses. Mr. Staplee Firth, who defended Mr. Hoffer, pointed out that this was not permissible, according to the principles of English common law, and that having been let off on the first count, the defendant could not be convicted on either of the other two. The Bench ultimately accepted this view, and dismissed all the summonses.

Scottish Enterprise.

WITHIN the next week or so all the scaffolding will be removed from outside the Argyll Company's new works at Alexandria which, with the extension now in progress, will eventually cover nearly fifteen acres. Even at present over 1,100 hands are employed, we understand, at these works alone, but when everything is in readiness this number will be nearly doubled. It is a striking example of Scottish enterprise that neither of the three leading firms—the Argyll Company, the New Arrol-Johnston Company, and the Albion Company—have been able to keep pace with their orders during the past year, the Arrol-Johnston Company having been especially busy since their victory in the Tourist Trophy Race, and the Albion Company since their performance in the Scottish Trials last May.

"Can England be Invaded?"

MR. WILLIAM LE QUEUX, who has been at work in conjunction with a number of experts, amongst whom, we are given to understand, Lord Roberts may be included, is just bringing out an elaborate treatise on the question as to whether England can or cannot be invaded, entitled "The Invasion of 1910." Mr. Le Queux states that in preparing the facts for his fiction, he had to make a strategic survey of the whole of the east coast of England, and this he did by means of a 40-h.p. Napier car, which in the course of his work carried him some 7,000 miles over all kinds of roads and covering a period of four months without ever compelling him to stop a single minute on account of the engine. This forms a good additional proof of the great importance of the motor car—a point which, by the way, has not been previously much dwelt on—for military survey purposes.

The False Character Question.

IN any industry in which the demand for employees greatly exceeds the supply, improper methods of obtaining situations are likely to be frequent. An alleged instance in point was provided the other day by Ernest Edward Rance, who was stated to have made use of a false character in order to enter the service as chauffeur of Mr. E. C. Javal, Managing Director of Messrs. Spiers and Pond. Not long previously Rance had, it was stated, been successful in smashing up a valuable motor, the property of his previous employer, was was consequently not exactly bubbling over with anxiety to recommend him to a new situation. Rance, however, produced a written character in which there was nothing about the smashed-up car. The charge was that the said character had been fabricated. Mr. Javal, who did not desire to press the case, said he only took proceedings on account of the very great danger to the public occasioned by this sort of thing, as Rance's character was not only misleading, but he was completely ignorant of motor car driving. Mr. Horace Smith, the magistrate before whom the case was brought, thought that there was more than met the eye in it, and he remanded Rance while the police instituted enquiries.

A "Haul."

AN illustration of the way in which our local journalists in some places, at any rate, still regard the situation, is provided by the title which a local quill-driver uses in referring to the recent proceedings before the Kingston Bench, at which seven motorists were fined, several of them as much as £10 on the usual charge, as "another haul of motorists." Amongst the victims were Earl Russell, who, as three previous convictions had been recorded against him, topped the list with a payment of £15.

Poor South Pole!

IT is almost time, one would think, that a society should be inaugurated for the protection of the South Pole from ill-considered onslaughts, for hardly a week, certainly not a month, passes without someone proposing another method of reaching that inaccessible and doubtless highly inhospitable spot. Dr. F. A. Cooke, of New York, is the latest aspirant for Antarctic fame, and he is said to be having three motor cars built for the purpose of making "a dash on the Pole." The cars, which are to be 12-h.p. machines, and are understood to be a wonderful combination of wheels and runners, are fitted, we are told, "like caravans," which probably merely means that they will be closed, and will carry provisions—an obvious necessity. Dr. Cooke intends to proceed by ordinary methods to a spot some 750 miles from the Pole, and then he will let loose his motor cars. We wonder whether any of the numerous paper Antarctic explorers will ever be prevailed upon to make an actual start.

Further Threatened Patent Litigation in America.

JUST in the same way that the early "Renault direct-drive" patent (No. 3981 of 1899), and also Daimler's "Mercedes gate" patent (No. 9805 of 1899), have been raked up over here recently, so in the United States there is some talk of attempting to enforce the payment of royalties on certain American patents that were taken out some years ago, but had been more or less forgotten in the meantime. Thus, for instance, Dyer's patents, numbered 657,650 and 662,401, filed on June 8th, 1898, and April 26th, 1899, respectively, are alleged to give a monopoly in the use of the "gate" system of arranging the change-speed-lever on cars, and the use of sliding spur-wheels in the gear-box. In connection with petrol engines operating on the 2-stroke cycle, moreover, Sintz's patent, No. 509,255, applied for on October 27th, 1892, and Cock's U.S.A. patent, No. 544,210, applied for on March 10th, 1894, are likely, it is said, to be heard of in the Law Courts shortly. Further than this, we learn that the Hartford Suspension Company are taking action to uphold their shock-damper patents, this Company owning Nos. 695,508 (Truffalt), 12,399 (re-issue), and 803,590 (Hartford). The Selden "master patent" bogey in America still, of course, holds very strong sway.

The "Automotor Journal" at the Agricultural Hall, March 24-31.

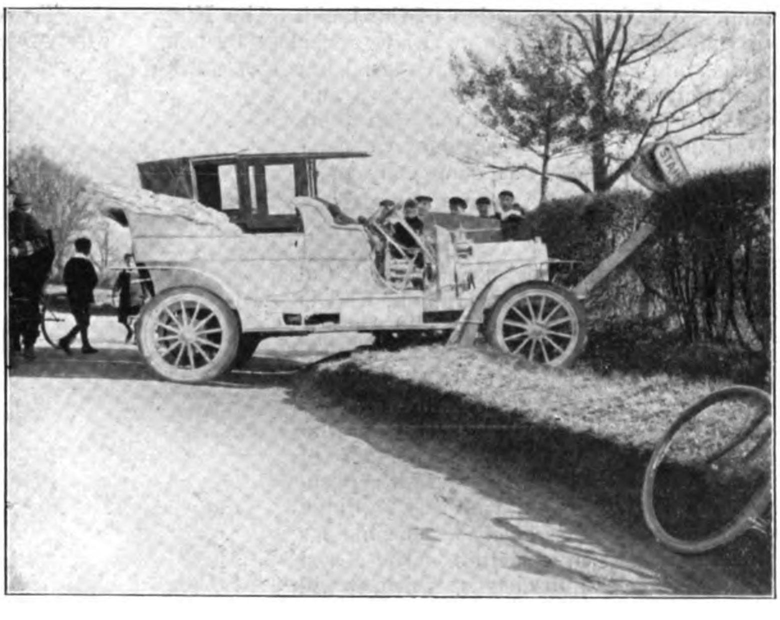
THE number of the Stand of THE AUTOMOTOR JOURNAL during Messrs. Cordingley's Motor Show at the Agricultural Hall will be 161, in the Large Hall, almost immediately facing the entrance to the Minor Hall.

Nice Carnival in London.

A VERY ambitious scheme is in course of organisation for carrying out a big Carnival at the Crystal Palace on the first two days of June, in aid of the Royal Waterloo Hospital for Children and Women. An extensive round of amusements has been specially arranged under the energetic organisation of Mr. E. Douglas White, and doubtless the motor car will play a prominent part in this "Nice" festival in London, in like manner to its employment at the French festivities. The Carnival should be a source of enormous attraction, especially in view of the good cause in which the effort is to be made.

Motoring Annual, 1906.

A NEW edition of this useful volume is now published, and is again conspicuous for the variety and wide range of the information contained. Thus, there is the extensive motorists' "Who's Who," the list of clubs and associations with their members and a *resumé* of the principal motoring events of the past year. Several pages of useful data, both mathematical and practical, forms another portion of the work, which includes a general directory of manufacturers and agents.



Last week a curious accident occurred at Fulwell, when two cars, owned by Colonel Fowle, of the 21st Lancers, and Mr. H. O. Mack, of South Kensington, respectively, came near having a very serious experience. The result is seen in our photograph above. They were proceeding towards Hampton Court and Staines, respectively, when they simultaneously reached the point where the main roads cross. In trying to avoid a collision, the two cars swerved round and dashed into the ditch, side by side, knocking down the signpost, which is seen lying in the hedge. Both cars were considerably damaged, but fortunately both the drivers, who were the only occupants of the cars, escaped without injury. Colonel Fowle's car is the white car in front—a 15-20-h.p. Brooke.

A 15-20-h.p. Brooke "Estate" Car.—This vehicle is one of the latest productions of the Brooke factory and has been specially designed for all round use at country houses. As illustrated it is convenient for station work, the front portion affording a comfortable and well-protected carriage for passengers, while the luggage is placed behind. By removing the top, the car can be converted into a shooting brake. Lord Linlithgow and Col. Charlesworth have already acquired similar vehicles.

A VERY sad motor car accident, of which the Marchesa Corsini di Lajatico, wife of the Equerry to the King of Italy, and herself a member of the great Barberini family, was the victim, occurred in Italy last week. The Marchese Corsini di Lajatico was himself driving his wife back to Rome, across the Campagna, when the car skidded and collided with a bridge wall. The Marchesa was thrown out into a ditch, and died immediately from concussion of the brain. The King of Italy was at once informed of the accident by telephone, and His Majesty, with his usual impulsive warm-heartedness, sent on his surgeons, and followed with Queen Helena. On their Majesties' arrival at the scene of the accident, the Marchese was completely prostrated.

Enfield Motor Cars.

WE omitted to mention last week the important part which Mr. Guillon, who is the works manager of the Enfield Autocar Company, will take in the work of introducing, on an extensive scale, the vehicles which the Enfield Company will shortly be placing on the market. Mr. Guillon, who has been a very successful designer of motor cars in France, and afterwards occupied a similar position with the Fabrique Nationale, Liege, is solely responsible for the design and manufacture of the Royal Enfield vehicles and chassis, which, it will be remembered, were on exhibition at Olympia in November last, and have since been seen at the leading shows in the country. Mr. Guillon will continue to occupy his position of designer to the new company combined with the responsibility of works manager. His practical knowledge and experience, together with the managing director, Mr. E. H. Lancaster's, knowledge of the requirements of the English and Colonial markets, should result in considerable benefit both to the clients of the company and the shareholders.

Further Vanguard Tours.

THE London Motor Omnibus Company are reviving the idea of organising a tour to the South of France with one of their 30-h.p. "motor coaches." The tour, it is announced, will occupy 30 days, and visit Avignon, Marseilles, Lyons, Hyères, St. Raphael, Nice, Monte Carlo, and Mentone and other interesting places, returning viâ Paris. It will cost each passenger a fee of £57 15*s.*, including hotel accommodation on the way, and all incidental expenses. Throughout the journey the tourists will be able to travel either outside or inside, as they may prefer, and they will be thus independent of temporary atmospheric unpleasantnesses.

A Suggestion for Enthusiastic Motorists.

THE Winton Motor Carriage Company have sent round an amusing "motto for office use," which takes the form of the following suggestion:—"If motoring interferes with your business, give up your business."

Motor Cars and Horse Shows.

AT the Richmond (Surrey) Royal Horse Show, which is annually held under the direction of the Richmond Horse Show Society, Ltd., this year the dates fixed being June 15–16, a feature is made of the exhibition of motor cars.

Edinburgh's Motor Fire Engine.

THE Scottish capital has just acquired one of the Merryweather "Fire Kings" at a cost of £1,150. It is a standard machine with water-tube boiler and oil burner.

A "TOURIST TROPHY" VAN.—This, the third White steamer in Liberty and Co.'s employment, is of particular interest on account of the fact that the chassis is that actually driven by Mr. Coleman in the Tourist Trophy Race. The mere fact that a Tourist Trophy chassis should be suitable for business purposes is significant, for it will be remembered that at one time there were some people who imagined that this race would only develop useless freaks.

The attractive centre picture of Cordingley and Co.'s Agricultural Hall Motor Show Poster.

The Agricultural Hall Exhibition.

NEARLY 300 individual firms will stage exhibits at Messrs. Cordingley's Motor Car Exhibition, opening next Saturday, March 24th, at the Agricultural Hall. We have already drawn attention to the many important associations, headed by the Motor Union, who will hold their important gatherings during the Show Week at the Hall, rendering the Islington venue the centre of a really important motor week from the 24th to 31st inst. The stand of THE AUTOMOTOR JOURNAL will be No. 161, almost immediately facing the entrance to the minor hall.

Dust Preventatives.

AMONGST the new preparations for rendering roads dustless with which it seems we are likely before long to be inundated, is mentioned a new and wonderful composition entitled "Newstrand." It is of a nice dark brown, you make as good a road surface as you can, and then you pour the "Newstrand" on it, wait till it is dry, and on that stretch of road you will never see dust again. At least that is what is said!

BRITISH EXPORTS AND IMPORTS OF MOTOR CARS, &c., FOR 1906.

NOTE.—In our issue for January 13th, 1906, we published in one table the full figures of British Exports and Imports for 1902, 1903, 1904, and 1905. Prior to 1902, motor cars were not classified separately.

1906.	Imports.

NEW COMPANIES REGISTERED.

Automixte (Limited).—Capital, £1,000 in £1 shares. Object, to carry on the business of motor car proprietors, &c.

Automobile Transit Trust (Limited).—Capital, £4,400 in 4,000 "A" shares of £1 each and 8,000 "B" shares of 1*s.* each. First directors, J. Simpson and I. B. Blaiberg.

Burke Engineering and Motor Company (Limited), Parnell Street, Clonmel, co. Tipperary.—Capital, £6,500, in £1 shares. Objects, to deal in motor cars, &c. (Irish company.)

Doherty Fittings Company (Limited).—Capital, £10,000 in £1 shares (5,000 "A" and 5,000 "B"). Object, to acquire the business carried on by J. Doherty and M. T. Hawkins at 21, Bishop Street, Birmingham, as Doherty and Hawkins, manufacturers of and dealers in cycle, motor car, and vehicle parts and accessories. First directors, E. H. Timson (chairman), J. Doherty, and M. T. Hawkins.

Enfield Autocar Company (Limited).—Capital, £150,000 in £1 shares. Object, to acquire from the Enfield Cycle Company, Limited, the motor car manufacturing business heretofore carried on by the said company at Enfield Works, Hunt End, Redditch. First directors, E. J. Seymour, G. H. Cartland, T. Evans, R. W. Smith, A. Eadie, and E. H. Lancaster.

Ernest Arnott and Holloway (Limited). — Capital, £5,000 in £1 shares. Object, to carry on the business of manufacturers of and dealers in vehicles of all kinds. First directors, E. Arnott and W. C. Holloway.

Excelsior Works, Coventry (Limited), 18, Hertford Street, Coventry.—Capital, £2,000 in £1 shares. Object, to carry on the business of manufacturers, repairers, and dealers in cycles, motor cycles, &c. First directors, E. H. Godbold, G. H. Green, V. Godbold, H. Evans, T. E. Donnison, C. Martin, and J. T. Fazakarley.

Hahnite (Limited), 16, Philpot Lane, E.C.—Capital, £2,000 in £1 shares. Object, to acquire the rights of R. M. Hahn for the United Kingdom in an invention relating to an improved oleaginous mixture for sprinkling on roads. R. M. Hahn, first managing director.

Motive Power Supply Company (Limited), 245, Union Street, Aberdeen.—Capital, £10,000 in £1 shares. Objects, to develop the sale of the Central Valve Internal Combustion Engine for fishing boats, yachts, barges, &c. (Scotch company.)

Pilot Motor 'Bus Company (Limited).—Capital, £100 in £1 shares.

Scottish Motor Syndicate (Glasgow), (Limited).—Capital, £2,500 in £25 shares. Object, to manufacture or deal in motor cars, cycles, &c. (Scotch Co.).

The Motive Power Supply Company (Limited), 245, Union Street, Aberdeen.—Capital, £10,000 in £1 shares. Object, to develop the sale of the central valve internal combustion engine for fishing boats, &c., patented by William Peck, F.R.A.S., Edinburgh.

Universal Motor (North America) Syndicate (Limited).—Capital, £4,100 in £1 shares (100 founders'). Object, to manufacture and deal in motors for traction, agriculture, trade, and other purposes, including the Motor for all Purposes and the Universal Motor, in the United States of America, Canada, and elsewhere. First directors, C. T. M. Wakefield and H. W. Bliss.

Victoria Carriage and Motor Car Company (Limited), 117, Broad Street, Hanley.—Capital, £2,000 in £1 shares. Object, to acquire the business of a carriage builder, carried on by T. A. Astle as Sargeant and Co. First directors, T. A. Astle and A. T. Poole.

Waltons and Company (Limited).—Capital, £1,000 in £1 shares. Object, to acquire the business of a cycle and motor manufacturer, &c., carried on by H. Walton, at Shorey Works, Dawson Square, Burnley, as Waltons and Company.

Wilson Thom Canal Power Syndicate (Limited).—Capital, £30,000 in £1 shares. Object, to acquire patents relating to the production and application of gas as a motive power for boats, barges, and other vessels.

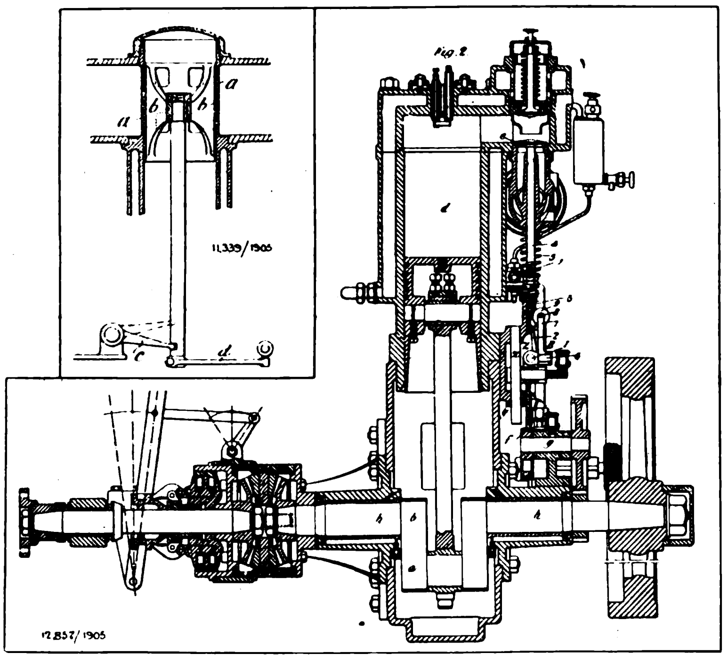
BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application ; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

11339. 30th May, 1905. Improvements connected with valves suitable for Regulating the engines of Motor Cars. Sir W. G. Armstrong, Whitworth and Co., Ltd., and Walter G. Wilson, Elswick Works, Newcastle-on-Tyne. It has before been proposed to regulate the supply of gas to the engine by a throttle-valve consisting of two co-axial cylinders having similar ports through them, the two ports exactly registering with each other when the maximum supply is required. In this invention two methods are provided for adjusting the effective size of the port, namely, by moving one cylinder axially relatively to the other and by rotating the same cylinder relatively to the other The advantage of this arrangement is that a much finer adjustment can be obtained than with a single movement, and this is especially the case when the valve is nearly closed. The two movements are given by different agencies, as the longitudinal movement by a treadle and the rotary movement by hand or by the governor. There are seven figures. Fig. 1 is a diagrammatic section of a valve operated according to this invention ; *a* is the valve casing and *b* the cylindrical valve. In this figure the valve is fully open so that the ports in the valve and casing coincide ; *c* is an arm operated by a treadle and engaging with a groove cut partly round the valve spindle ; *d* is an arm fixed to the valve spindle and operated by hand by a wire.—February 21st, 1906.



11,339/1905

12857/1905

12857. 21st June, 1905. Improvements in Marine Paraffin Motors. Daniel Goedkoop and Jan Goedkoop, Kromhout Motor Works, Amsterdam. This invention relates to marine engines driving the screw-propellers of boats, and actuated by the combustion of a mixture of vaporised paraffin and air in proper proportions, the driving-shaft of each motor engine being connected with the screw-propeller in such manner that the latter can be stopped or reversed. There are five figures. Fig. 2 is a vertical longitudinal section. The improved paraffin marine motor is of vertical, single-cylinder, four-stroke-cycle, slow-speed type, the speed being from about 340 revolutions per minute of the smallest size engine to about 250 revolutions per minute of the largest size. The motor is self-contained, and the reversing-gear and thrust-bearing for the propeller may be of any suitable kind, but preferably they are fixed upon the casing, *a*, in which the crank, *b*, revolves, this casing being closed in the usual way, and containing lubricating oil. The inlet-valve of the engine is automatic in its action, being opened by the pressure of the air drawn into the cylinder, *d*, whilst the exhaust-valve, *e*, is operated by an eccentric, *f*, fixed upon a half-time geared shaft, *g*, made to revolve at half the speed of the crank-shaft, *h*. The mode of ignition is electric, the spark being obtained by a low-tension oscillating magneto apparatus of the well-known kind driven from the same shaft, *g*, as the exhaust-valve, *e*, with make and break contact of the kind usually used in low-tension ignition-apparatus, moved from the oscillating lever of the magneto apparatus. The oil or paraffin is forced into the cylinder, *d*, with the air, by means of a small plunger-pump, *j*, driven from the same eccentric, *f*, which operates the exhaust-valve, *e*. This eccentric also actuates a small inertia or pendulum-governor at B, which, when it is brought into action by any increased speed of the engine, operates (on the well-known hit-or-miss system) so as to stop the working of the exhaust-valve, *e*, and at the same time to prevent the paraffin-pump from operating. When the motor is first started and the vaporiser cold, a small quantity of petrol is used instead of paraffin, and when this petrol has been consumed the vaporiser is hot enough to continue the working with paraffin. The speed of the motor can be diminished to a certain extent by reducing the stroke of the fuel-pump and thereby the supply of paraffin. The eccentric, *f*, fixed upon the half-timed eccentric-shaft, *g*, geared with the engine-shaft, *h*, has its rod connected by a pin with a cross-head above, which is accordingly made to move up and down vertically, being guided by means of a strong bar or pin, *x*, fixed to it and working in guides, *y*, carried by the frame of the engine. Upon the upper part of this crosshead is formed a bracket, *z*, in which is pivoted, upon a long pin, 1, at right angles to the crank-shaft below, a boss carrying a strong vertical lifting-arm, 2, the upper end of which has a somewhat angular edge (parallel with the pin 1), which actuates when necessary a corresponding sliding-piece or bar, 3, the lower end of which has a corresponding angular edge, and the upper end of which (when the lifter, 2, is vertical) engages with a bar or block sliding in vertical guides, the upper end of which, when sufficiently raised, strikes the lower end of the exhaust-valve spindle, 4, which raises it against the pressure of a helical-spring, 5, round the valve-spindle. If, however, the lifting-bar, 2, is turned out for a short distance, it escapes the sliding-bar, 3, actuating the exhaust-valve spindle, 4, and the valve (which has been closed by the spring, 5) remains closed. In order to determine the position of the lower knife-edged lifter, 2, as required and as influenced by the speed of the engine, the boss at the lower end of the lifting-bar, 2, which turns upon the pin, 1, in the bracket, *z*, on the crosshead, *w*, has projecting from its front a horizontal-pin, 6, upon which turns the lower end of the vertical-arm, 7, of a bell-crank, the upper end of which is fitted with a horizontal-pin, 8, upon which revolves a light wheel or disc, 9, having an annular groove round its circumference, the axis of the disc being parallel with the pin, 1, in the bracket upon the crosshead, upon which the angular lifting-bar, 2, turns as above described. The grooved disc, 9, is arranged so that if the vertical-arm, 7, of the bell-crank upon which it is pivoted is vertical, the lifting-bar, 2, is also vertical, and actuates the sliding-piece, 3, above, and the exhaust-valve, whils if it is turned slightly out the lifting-bar, 2, does not come in contact with the corresponding sliding-piece, 3, above, and the exhaust-valve remains closed, the wheel running upon an angular fixed rail during the upper part of its stroke. The movement of the lifting-bar, 2, from its vertical position is determined by the governor—a normally horizontal arm of the bell-crank, carrying an adjustable weight, the governor being held in this position by a helical-spring, which is wound round the prolonged pin, 1, in the crosshead, upon which the boss, carrying the lower angular lifting-bar, 2, turns, one end of the spring being bent laterally under the horizontal-arm of the bell-crank, and the other end being held by a socket fitted upon the outer end of the pin, 1, the strength of the spring being adjusted accurately by adjusting and fixing the socket in its position. The tendency of the spring is both to lift this weight and the horizontal-arm of the governor, and also to press the valve lifting-bar against the guide-bracket of the engine. In this position the exhaust-valve, *e*, is lifted at every revolution of the eccentric-shaft, *g*, but if the speed of the motor becomes too high, the inertia or downward pressing force of the weight, when the crosshead moves upward, becomes greater than the lifting force of the spring, and the bell-crank lever turns slightly, its vertical-arm, 7, moving sufficiently (between stops on the lifting-arm) to bring the grooved disc, 9, opposite to a corresponding fixed inclined guide-rail, along which it runs as the crosshead rises and falls, the lifting-arm, 2, being at the same time moved out at a slight angle, so that its upper edge escapes the corresponding edge on the upper sliding-piece, 3, and the valve-spindle, 4, remains inoperative until the motor falls to its normal speed. The sliding-piece, 3, thus left unmoved, also fails to operate the pump by which the paraffin fuel is injected, so that in this position of the governor the pump remains unaffected.—February 21st, 1905.

PASSING EVENTS.

A Good Year's Work.

The Motor Union is to be very sincerely congratulated on the year of strenuous work which lies behind it, the main features of which are embodied in the Annual Report which has recently been sent out to the members. The number of fields of activity in which the Union has contributed to the advantage of the automobile movement is quite remarkable, but three special departments may be selected out of much useful work as of particular importance and value to the future of the movement. We refer specially to the action of the Union in regard to speed limit applications and enquiries, prosecutions undertaken by the Union against ordinary offenders against the highway laws, and last, and perhaps most important of all, the Motor Union's work in placing evidence before the Royal Commission.

The increased energy displayed by the police soon after the new Act came into operation in 1904, resulted, as many of our readers know to their discomfort, in a large increase in the number of police prosecutions, and that increase was continued throughout last year. The advantage to members of being able to readily obtain legal advice of a reliable character is accordingly increased. Localisation and the formation of the "Legal Cases Committee" of the Union has proved of the greatest use in supplying for all members expert legal advice and information free gratis, and for nothing. In connection with the same line of usefulness, a large number of solicitors have been specially appointed by the Union, in different parts of the country, who can be relied upon by local automobilists as possessing special experience in motor car law.

The large amount of work which the officials of the Motor Union have got through in fighting applications of local bodies for a speed limit of 10 miles per hour, may be judged from the fact that they have had to fight during the past year no less than eight different applications, in the majority of which the Union has been successful in preventing the imposition of this highly arbitrary restriction.

It is in connection, however, with the Royal Commission on Motor Cars that the Union has assisted, in conjunction with the Automobile Club, in performing what may eventually prove to be one of the most important services rendered to the automobile cause since the Union was founded. On the appointment of the Royal Commission, a Joint Committee of the Club and the Union was formed (each body contributing £500 to a Defence Fund) to enable the automobile case to be adequately placed before the Commission. A number of prominent automobilists were accordingly fully heard by the Commission, and there can be little doubt that the valuable character of the evidence they tendered will become fully apparent when the Commission publishes its report.

The Motor 'Bus in Berlin.

Among the advantages of not allowing locomotion, and particularly tramways, to be in the hands of an elected body which, having once committed itself to a line of policy, feels compelled to stick to it, is afforded by what is now occurring in Berlin. The Berlin General Tramway Company has become convinced of the greater advantages possessed by the motor 'bus for dealing with traffic than those provided by the electric tram, and have decided to embark on a large scale in the motor omnibus business. Unfortunately, until recently, one of those limiting and restricting laws, of which the object is usually more or less incomprehensible, prevented the tramway company from running 'buses. This has now been rescinded, and Berlin will consequently witness the spectacle, which would certainly make a Londoner rub his eyes, of a tramway company catering for public traffic by a service of up-to-date motor 'buses. Possibly, however, if we wait long enough, London may ultimately to some extent emulate Berlin in this respect, Captain Hemphill, vice-chairman of the Highways Committee of the L.C.C., having this week stated that it was *possible* that the Council some time in the future might approach Parliament for powers to run motor 'buses as feeders to their trams. The Berlin tramway company have been largely induced to take this step by the narrowness of many of the streets through which their service runs, and the congestion which naturally follows when a sufficient number of trams follow in close sequence upon one another. In adopting this policy the Berlin Tramways Company will undoubtedly benefit both the general traffic facilities of their capital and increase their own earning power.

◆ ◆ ◆

In the Enemy's Citadel.

There is only one spot in the whole world more sacred to the worship of the horse as an institution than Aldridge's, in Upper St. Martin's Lane. It is the second great centre in the country, the second head-quarters of the horse trade. We may be sure, therefore, that most of our readers will rub their eyes and wonder where they are when they see an ordinary advertisement this week announcing that no less than seven automobiles are to be sold by auction in the well-known horse fair, just as if they were so many horses. We trust there will be no ructions. If the horse, or horses (there are usually a good number of them on sale now) become restive at seeing the temple hitherto sacred to their sole worship invaded by their modern competitor in this manner, we may anticipate a stampede down St. Martin's Lane, and a public demonstration in Trafalgar Square. If any of our readers should on Thursday next, therefore, observe a body of determined and angry horses marching in procession upon the spot where the grievances of the masses have been previously aired, they will now know what the portent signified—the invasion of Aldridge's by the automobile.

◆ ◆ ◆

The "Automotor Journal" "Buyers' Guide" to Commercial Motor Vehicles for 1906.

Saturday (to-day) will see the opening at the Agricultural Hall of another in the long series of automobile exhibitions which Mr. Cordingley has organised with such conspicuous success in the past, and so greatly to the general benefit of the automobile movement. By the natural course of events, and the arrangement of other exhibitions, it may be anticipated that a prominent feature of the approaching show (especially when we consider the motor 'bus boom, which expands more and more every month, and even every week) will again be the commercial and heavy vehicles. We accordingly have selected the present occasion as a suitable one for publishing THE AUTOMOTOR JOURNAL "Buyers' Guide" dealing with the commercial and heavy automobiles now on the market. The "Guide" is exactly uniform with our tourist car "Buyers' Guide for 1906," which we published on February 17th, and will enable all who are considering the purchase of commercial vehicles to select those that best suit their requirements. The development of heavier types of automobiles has been so phenomenal during the last few months, and the demand for them has been such a rapidly increasing one, that we feel sure THE AUTOMOTOR JOURNAL "Guide" will be of general service and utility to our readers. A considerable number of the vehicles that are included in our tables are to be on view in the Agricultural Hall.

◆ ◆ ◆

The Police and the Motor Cab.

To predict that the general triumph of the motor omnibus will before very long be followed by an equally imposing triumph on the part of the motor cab, is a prophecy which even cautious people like ourselves may be excused for almost venturing upon. The motor cab is certainly appearing in considerable force on the streets of the Metropolis, though not yet in such force as seriously to affect the general traffic or to add much to the convenience of the travelling public. With moderate fares, and particularly, as we have hinted more than once, if it adopts the taxameter, the motor cab, when it does arrive in force, may feel assured of reaping a very satisfactory monetary harvest.

The moderate number of motor cabs at present on the London streets is no doubt to a large extent due to the difficulties inherent in designing a thoroughly satisfactory vehicle. There has been far too much tendency to take chassis that are originally intended for touring car purposes, and simply finish them off as cabs by attaching more or less suitable bodies to them. This by no means necessarily makes a satisfactory vehicle for London streets. The attitude of the police, too, as licensing authorities, has been decidedly cautious and conservative. The licensing of motor cabs as hackney vehicles comes under the provisions of the Act of 1869, under which the police have made certain regulations, most of which of course do not apply to motor vehicles at all, but to their previously published regulations they have added the further requirement that every motor cab must be able to turn round in a radius of 25 ft. Opinions are rather divided as to the wisdom of this requirement. Those makers who have succeeded in constructing cabs that comply with it are not much opposed to it. Others, of course, regard it as a piece of red tape. That a motor cab should, however, be able to turn round in most of our London streets without backing certainly seems desirable, and this it would appear is what the police have been aiming at.

◆ ◆ ◆

The Whole Subject in a Bit of a Muddle.

The situation at present savours somewhat of bemuddlement. It is no great wonder that this should be so, when motor vehicles have to be brought under the provisions of an Act passed as long ago as 1869. The police have published certain regulations which must be fulfilled before they grant the certificate of fitness—an indispensable condition to obtaining a licence, for which £2 has to be paid. These regulations comprise some antique provisions which it would be rather funny should the police insist on enforcing with regard to motor cabs. Among these may be mentioned :—

> "That all carriages fitted with noiseless or rubber-tyre wheels have bells affixed either to the carriage or to the harness of the horses drawing the same.
>
> That an iron frame and chains, or some equally efficient means for securing luggage carried on the roof, are fixed on the outside of all four-wheeled carriages."

while in addition a special attempt is made to deal with self-propelled vehicles by the following provision :—

> "Proprietors of carriages propelled by mechanical means will be required to furnish a certificate from an independent firm of engineers that each carriage submitted for licensing is, so far as the mechanism is concerned, fit for public use."

—a naive provision, which no manufacturer is the least likely to have any difficulty in fulfilling, while over and above these requirements there is the provision referred to above, of turning in a 25 ft. radius. When, however, you have fulfilled these and all the other police regulations, it does not follow by any means that you get your certificate of fitness, for to the regulations is appended the following suggestive note :—

> "NOTE.—Though the above conditions may have been complied with, yet if there be anything in the construction, form, or general appearance which, in the opinion of the Commissioner, renders the carriage unfit for public use, it will not be licensed."

Practically, therefore, the licensing of a vehicle rests entirely with the discretion of the particular police officials concerned. As regards the legality of the position, it often happens that on probing into things of this kind, surprises are forthcoming. According to a special Act, all regulations made under any Act of Parliament have, we understand, to be laid on the tables of both Houses of Parliament. One cannot help wondering if this has been done in the present case, and whether, if so, the somewhat humorous note quoted above formed part of them.

◆ ◆ ◆

A Select Committee on the Question.

The whole position therefore is, as will be seen, in a far from satisfactory condition, and includes elements of the absurd and incongruous as well as of the antiquated, and we accordingly trust that the proposal to appoint a Select Committee to inquire into the whole question and make its recommendations to Parliament will speedily be carried out. The terms of reference to the proposed committee include :—

1. The licences of drivers and conductors and the measures required to prevent the use of licences by unauthorised persons.
2. The restrictions imposed on cabs with regard to the carrying of passengers.
3. The treatment of cabs by the railway companies.
4. The structural requirements to be enforced in the case of motor cabs and omnibuses.
5. The readjustment of cab fares, in connection with taxameters, nd extension of the four-mile radius.

It is to be hoped the committee will report quickly, as legislation is obviously needed. This branch of the industry cannot be expected to attain full development while the law and the police regulations made, whether legally or not, are in their present condition. Early legislation is, therefore, needed, and we trust that the committee in question will get to work as soon as they can, and present a report which may as soon as possible form the basis for framing a useful and comprehensive Bill. In the meantime, perhaps, the police will be good enough not to take too rigid an attitude on the question, and above all remember that the 25 ft. radius test, though perhaps desirable as an ideal, might, at any rate as far as pioneer motor cabs are concerned, be relaxed to a certain extent without very seriously endangering the public safety.

⊕ ⊕ ⊕ ⊕

THE statements in the Press that the Board of Trade has sanctioned a speed limit for tramcars of 16 miles an hour in some parts of London, appear, from a statement made by the Board to the Roads Improvement Association, to be premature.

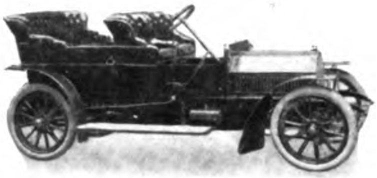
How to Recognise the Cars of To-day.

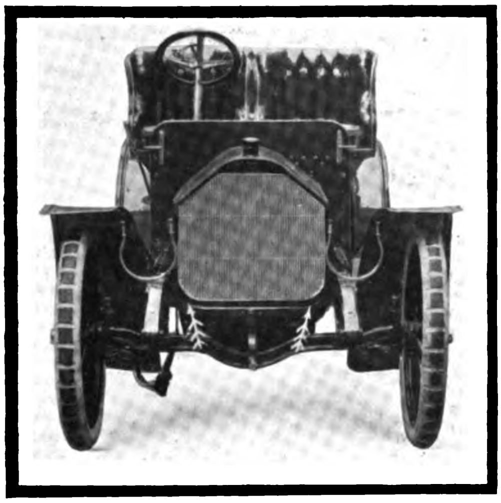
(No. 13).

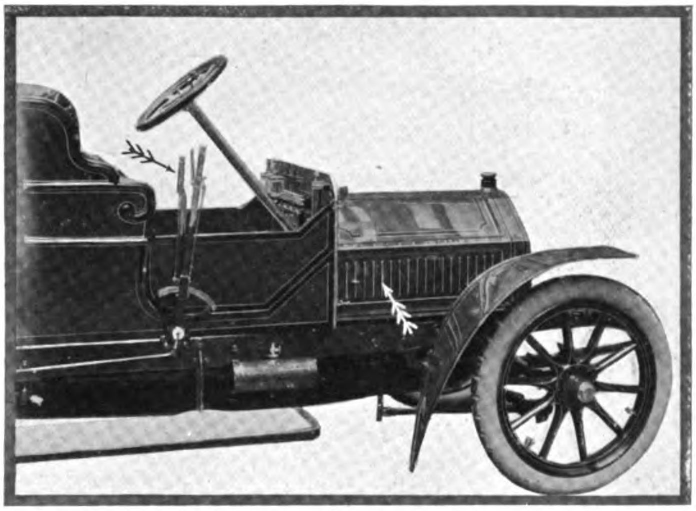
The Regent.

(GERMAN)

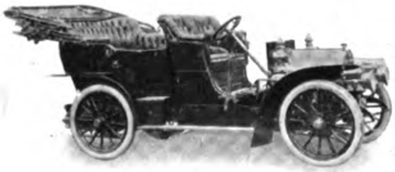
18 H.P.







The Regent Car is not easily distinguishable at first sight, but two important details are the LOUVRES IN THE SIDES OF THE BONNET and the ROUNDED CORNERS at the bottom of the honeycomb RADIATOR. Another feature is the CHANGE SPEED LEVER, which operates over a "STRAIGHT THROUGH" QUADRANT. DOORS are also fitted between the front seat and the Dash.

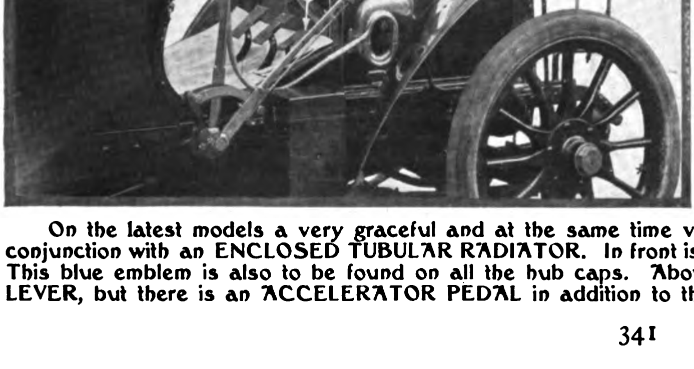


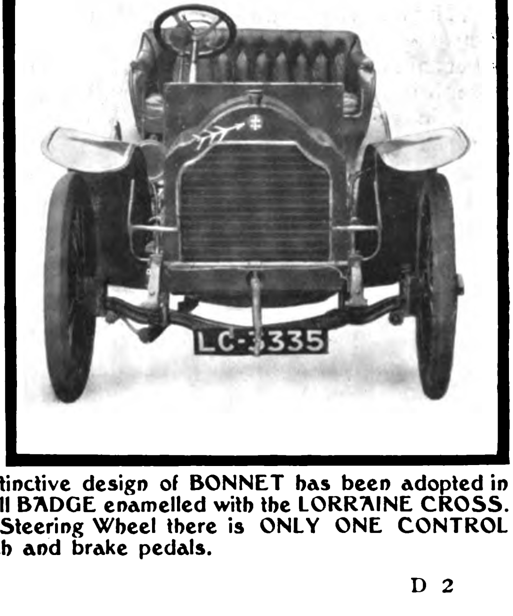
(No. 14).

The De Dietrich

(FRENCH)

12-15, 16-20, 24-30, 40-50 & 60 H.P.





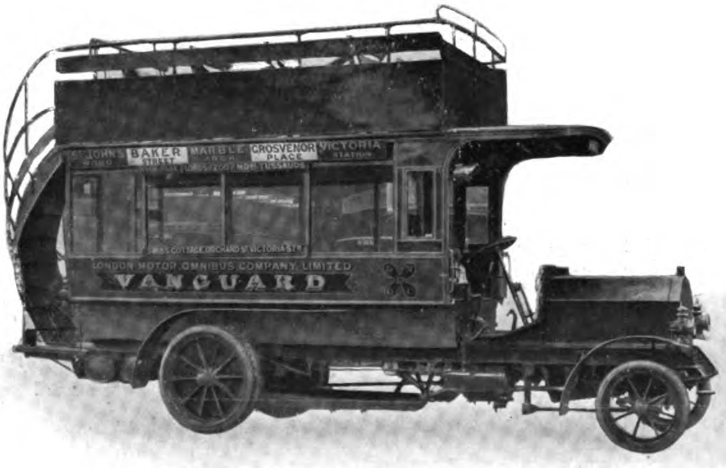
On the latest models a very graceful and at the same time very distinctive design of BONNET has been adopted in conjunction with an ENCLOSED TUBULAR RADIATOR. In front is a small BADGE enamelled with the LORRAINE CROSS. This blue emblem is also to be found on all the hub caps. Above the Steering Wheel there is ONLY ONE CONTROL LEVER, but there is an ACCELERATOR PEDAL in addition to the clutch and brake pedals.

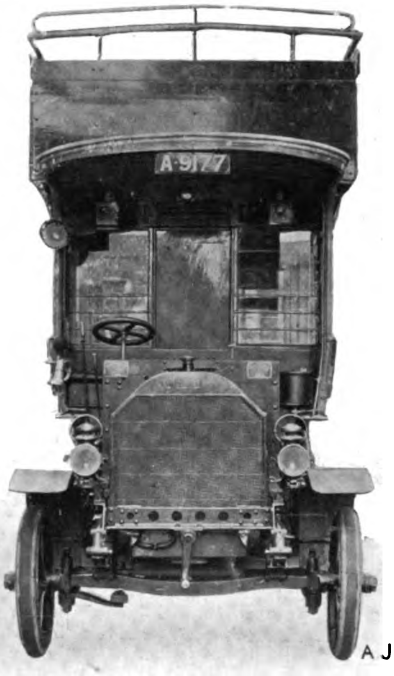
How to Recognise the Motor 'Buses of To-day.

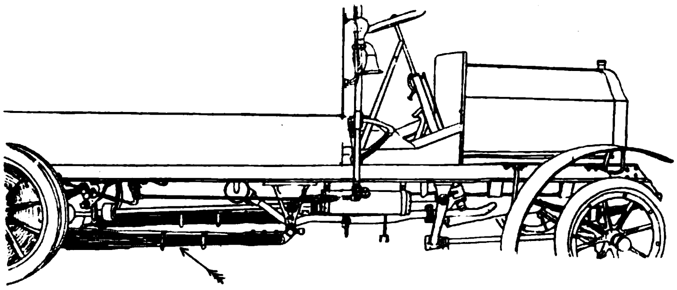
(No. 1).

Milnes-Daimler.

(GERMAN).







These vehicles are manufactured by the same firm as the famous Mercedes Touring Cars, and they have the same type of BONNET AND RADIATOR. At each side, beneath the frame, is a long WOODEN BEAM which takes the place of a radius rod, and it is by these that the vehicles can be most easily identified when passing.

'Bus and Cab Drivers the Best Motor Drivers.

It is satisfactory to hear that the motor omnibus companies declare that the men who make the best drivers are former horse 'bus drivers and cabmen. They learn, it is stated, quicker than others, and being at home in traffic are much more reliable, and possess the control over their nerves and tempers which is so absolutely essential. It is pleasing to learn that this is the case, as many people fancied that the advent of the motor would mean considerable distress for the men who, in many instances, are finding their occupation gone from no fault of their own.

A Petrol Famine?

It would seem that the immense increase in the consumption of petrol, which the addition of motor 'bus development to ordinary car consumption is occasioning, begins to make itself felt in the price of petrol. The *Petroleum World* calculates that 500 motor 'buses running for a year would alone consume a grand total of 3,000,000 gallons. The price of petrol, at any rate, has gone up ½*d.* per gallon, and our contemporary assumes that this rise is due to the enormously increased demand. But with products of the oil wells one never really knows. It may be only "manipulation" after all. If the demand goes on increasing, and no new sources of petrol are discovered, we may all agree with the *Petroleum World* that a rise is certain.

A Belgian Wonder.

There is no age limit as far as youth is concerned in the manifestations of genius, and there is equally no limit, apparently, to what the descriptive reporter will do with a subject he only imperfectly understands. As an example of both, we quote the following, which it would be a decided pity to alter by a single word:—

> A girl of this town (Antwerp), not yet fifteen years old, has patented a remarkable invention, consisting of a turn-table for reversing the direction of motor cars. The apparatus is fixed on the chassis, which has a driving-wheel at each end, and is worked by an electric motor. The invention was the outcome of watching the difficulty of manœuvring heavy motor wagons in the Antwerp streets.
>
> After watching the motor wagons for some time one day, the girl went home and by the next morning had a complete scheme for the turn-table. Two motorists who were visiting her father fetched a designer, and the plans were at once drawn up at the child's directions.

THE HUMBER PETROL CARS.

FOUR AND SIX-CYLINDER MODELS.

Few cars have been attracting more attention of late than have the products of the famous Humber Works, particularly now that they are making both 4-cylinder and 6-cylinder models. With steady persistency the engineers responsible for the design of these vehicles have been adding improvement after improvement, while always keeping in check that most important of factors—cost of of production. As a result the Humber Company are building cars which embody most of the best principles of modern practice, while retaining that desirable moderation in price which enables them to be "popular" by directly appealing to the pockets of the majority. Of these vehicles, we purpose dealing chiefly, in the present article, with the cars constructed at Beeston, under the superintendence of Mr. T. C. Pullinger. These consist of two models:—the 16–20-h.p., which has a 4-cylinder engine, and the new 30–40-h.p., which has a 6-cylinder engine. Both are in general respects similar, but on the larger model a spring-drive device has been incorporated which allows the engine to make three-quarters of a revolution before the road-wheels need begin to move. An additional foot-brake enclosed in the back-axle casing is also fitted, but the other details coincide for the most part with those now fitted on the 16–20-h.p. car. Turning our attention in the first instance to the details of the 16–20-h.p. car—the chassis of which is

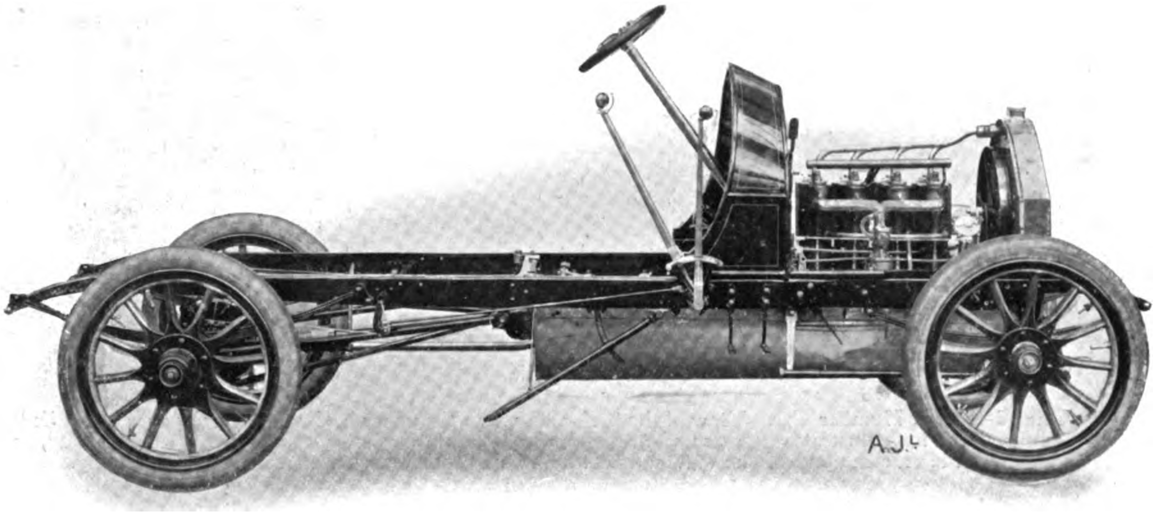


Fig. 1.—The 16-20-h.p. Humber Car. Side view of the chassis, showing metal sheath beneath engine and gear, which is fitted in order to protect them from dirt. The sprag is also visible, and it will be noticed that it is attached to a quadrant guide in order to steady it.

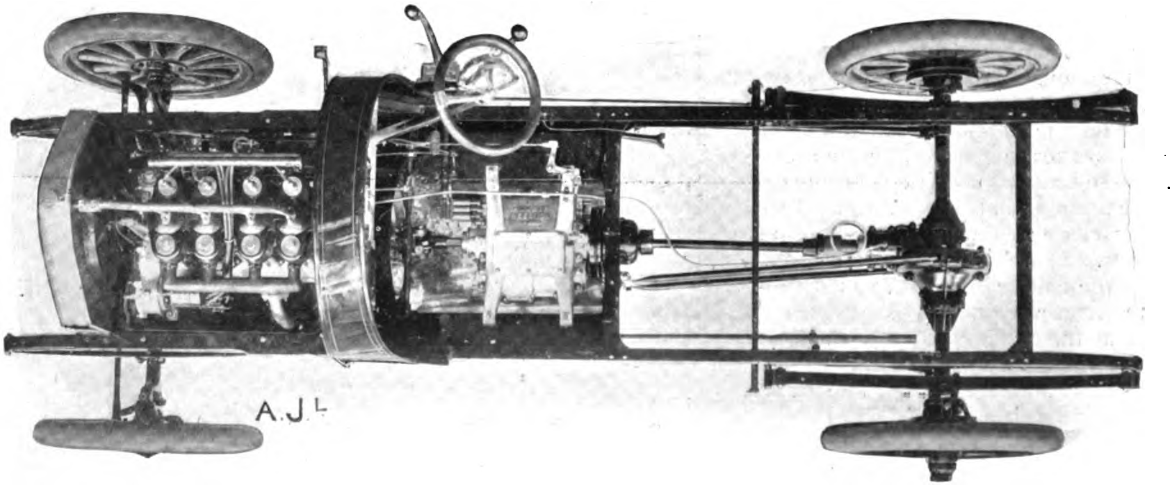

Fig. 2.—The 16-20-h.p. Humber Car. View of the chassis from above, showing the arrangement of the gear-box. Alongside the propeller shaft is seen the triangular torque-rod which ties the axle-casing to the frame and prevents it twisting round under the driving strain.

seen from the side and from above respectively, in Figs. 1 and 2—this has, since last year, undergone some important modifications, although in general it retains the characteristics of its predecessor.

In this, its latest form, it has a typical live-axle chassis and is fitted with a 4-cylinder engine in which has been embodied a special system of lubrication. The power is transmitted through a leather cone clutch to a 4-speed "Mercedes" gear-box, in which both shafts run on ball-bearings, and from this the drive passes through a universally jointed propeller shaft to the live-rear-axle. In this latter member such modern improvements as a horizontal division to the differential casing, and an extra bearing for the bevel pinion, have been adopted, while the road wheels run on tubular extensions of the axle casing and are fitted with ball-bearings.

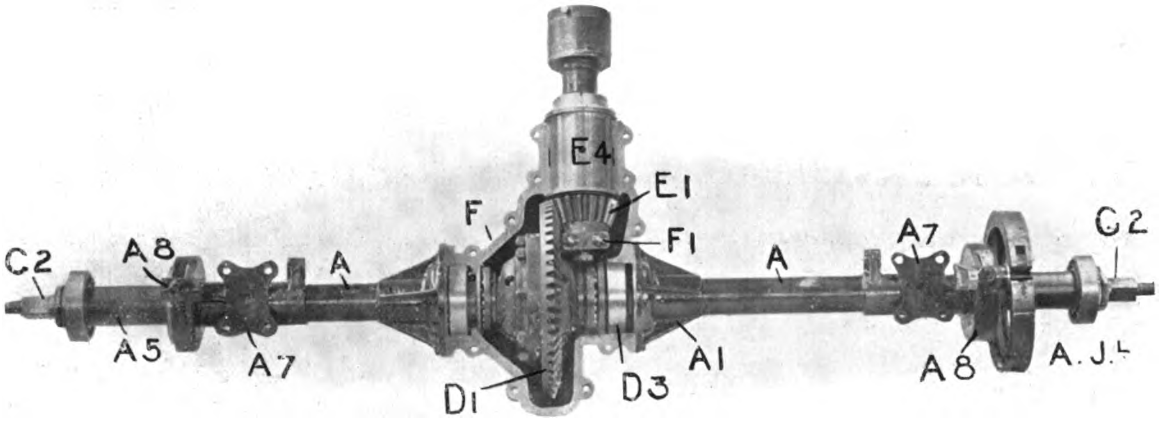

Fig. 3.—The 16-20-h.p. Humber Car. View of the back-axle when the upper half of the casing over the differential has been removed. This illustrates the accessibility of the bevels and shows the additional bearing, F^1, which supports the extreme end of the driving-bevel spindle and so prevents it from being overhung.

The 16–20-h.p. Back Axle.

In Figs. 3, 4 and 5 the details of the back axle construction are clearly indicated.

Surrounding the live-axle, C, is a stationary tubular casing, A, which extends on either side of the differential casing, F; the solid drawn steel tubes, A, being rigidly fixed to the central casting, F, by means of the flanges, A^1. Near their outer ends the tubes, A, are fitted with brackets which support the springs on the flat-plates, A^7, and hold the side brakes in position by the arms, A^8. These brackets are visible in Fig. 3, but the arrangement of the various parts is most clearly shown by the drawing in Fig. 5. Quite close to the bracket is one of the ball bearings, A^4, which support the road wheels, the other, A^3, being placed at the extremity of the tube, A. It will be noticed that the two ball bearings, A^3 and A^4, are not the same size, the inner bearing, A^4, having the larger diameter. This is in order to enable the inner bearing to be more easily fixed in position and removed, and on the same grounds it facilitates the removal of the wheel itself—which is the more important fact from the motorist's point of view, because it is seldom necessary to take down the bearings themselves. Another point to be noticed is that the bearings are placed on the axle casing so that they are between that stationary member and the wheel, instead of being between it and the live shaft. There are several obvious advantages in this construction; for instance, it enables the bearings to be of a much larger diameter than they can conveniently be made if they immediately surround the axle. Besides this, it allows the axle itself to be of minimum weight and of uniform thickness throughout because the revolving shaft carries no load, being merely subjected to the simple torsional driving strains. Between the two bearings, A^3 and A^4, is a distance sleeve, A^5, so that the lock-nuts, A^2, securely fix both bearings in position.

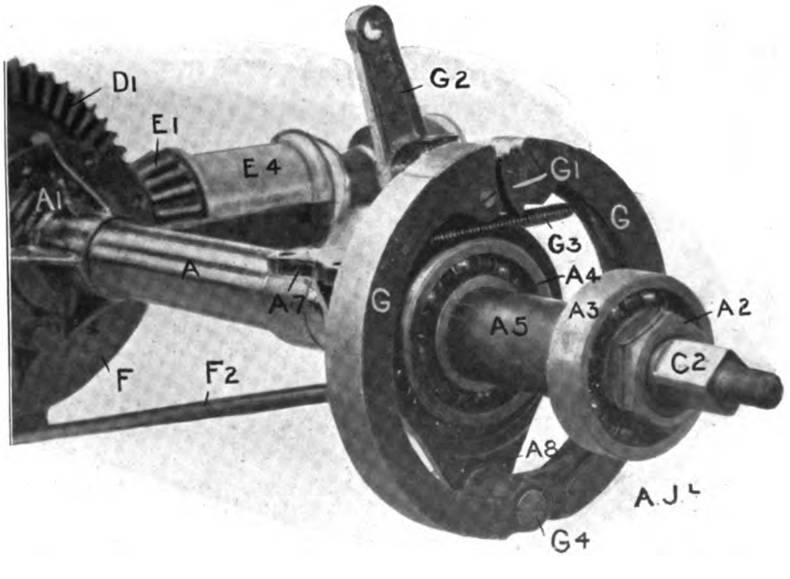

Fig. 4.—The 16-20 h.p. Humber Car. View showing one end of the back-axle after removing the road wheel. The road wheel is carried by the two ball bearings, A^3 and A^4; its weight is, therefore, supported by the end of the axle-casing, and not by the live-axle itself, which merely drives the wheel through the square coupling, C^2. One of the internal expanding brakes is very prominent in the view, and the rocking wedge, G^1, by which the shoes, G, are forced against the drum, can also be quite clearly seen.

No loose pieces are employed for transmitting the drive from the projecting end of the shaft, C, to the road-wheel, the hub, B, being cast with a square socket, B, which engages direct with the corresponding end, C^2, of the live-axle. The wheel is retained in place by the nut, C^1, while the live-axle is similarly secured by a nut, C^5, at its inner end. For lubrication, the entire hub is filled with grease, and a dust-tight joint is formed at the inner side by the soft washer, A^6.

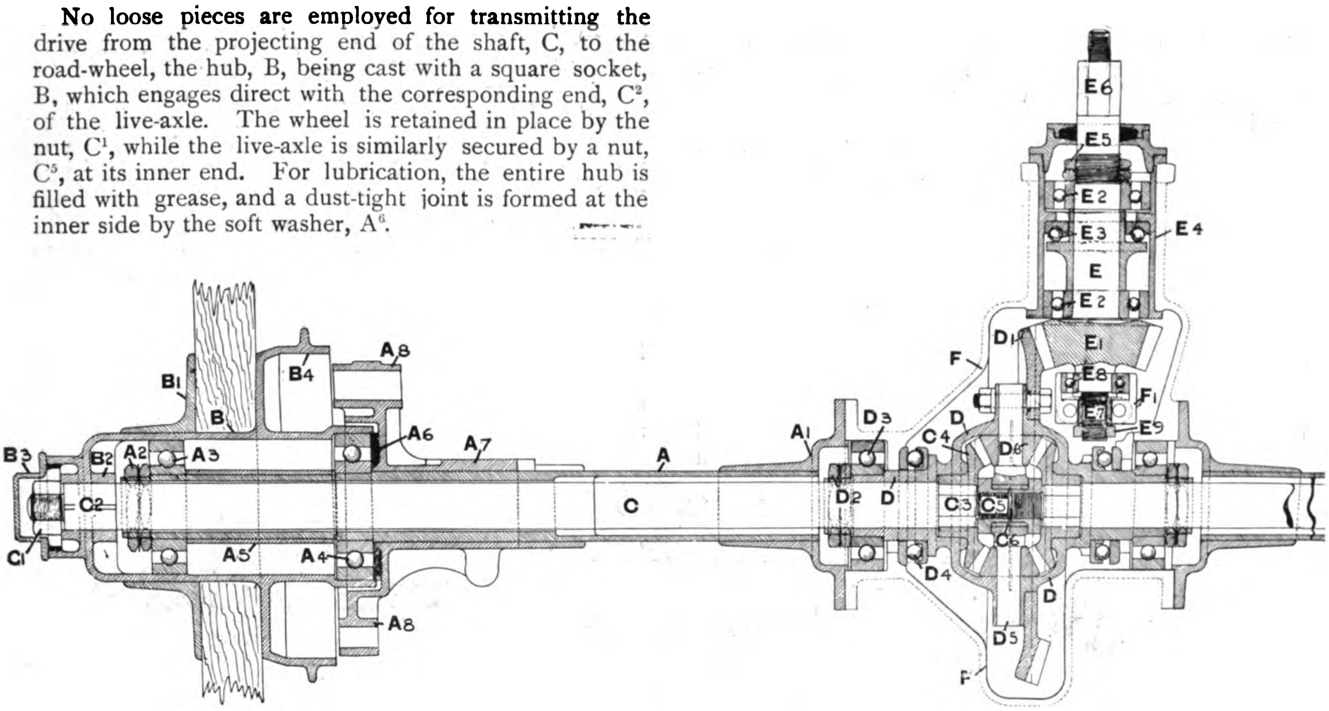

Fig. 5.—The 16–20-h.p. Humber Car. Sectional drawing illustrating the internal construction of the back-axle. This clearly shows the mechanism of the differential and the manner in which the halves of the live-axle itself are connected by it. For convenience only half the complete drawing is reproduced, but the ends, which carry the road-wheels, are, of course, alike.

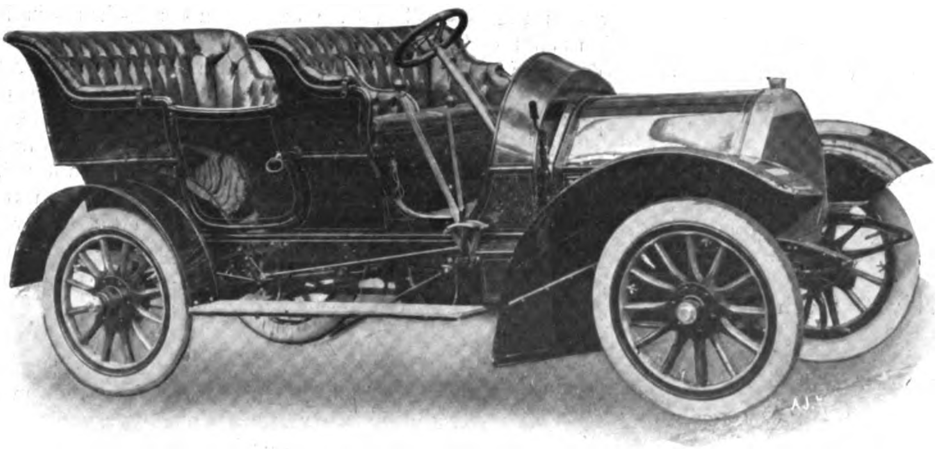
The internal construction of the differential-gear is also very clearly indicated in Fig. 5, but Fig. 3 shows how the casing, F, is divided by a horizontal joint in order to facilitate a thorough inspection without taking down the axle. The live-axle, C, is, of course, in two parts, and the inner ends, C^3, of each, terminate inside the differential-box, D, where they carry the bevel-wheels, C^4, which are secured in place on the hexagon-ends of the shaft by the nuts, C^6. It will be noticed that the nuts, C^5, are turned down—so that they are partly cylindrical on the outside—and fit into a common sleeve, C^6, which keeps the two shafts in alignment. Surrounding this sleeve, C^6, is a steel ring, from which project four spider arms, D^5, for the purpose of carrying the small bevels, D^6, of the differential-gear. The outer ends of the arms, D^5, are clamped between the flanges of the differential-box, D, so that the spider affords a rigid support for the sleeve, C^3, which aligns the ends of the live-axles. Ball-bearings, D^6, carry the differential-box, D, itself, and the bearings are locked in place by the nuts, D^2.

It is obviously impossible to remove the differential-box, D, from the casing, F, in one piece, because in order to do so it would first be necessary to draw out the live axle, and this is prevented by the nuts, C^5. If it is essential, therefore, to take out the differential-box for repair at any time, the car must be chocked up, and the axle-casing, A, itself taken down, and separated from the differential-casing, F. After breaking the joint in the differential-box, D, the nuts, C^5, can be removed, and each half of the box drawn off the live-axle separately.

Bolted to the flanges of the differential-box, D, is the large bevel-wheel, D^1, which is driven by the bevel-pinion,

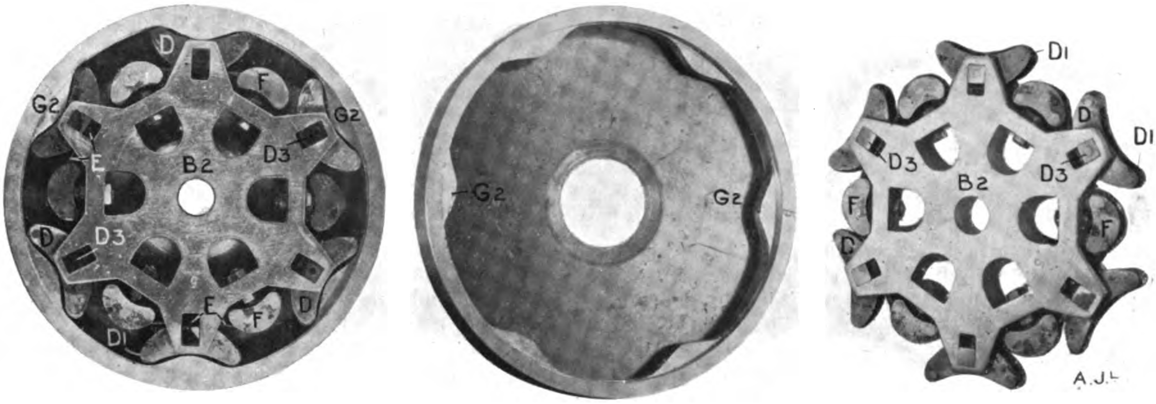


The 16–20-h.p. Humber Car.—One of the new 16–20-h.p. Humber cars fitted with the standard side entrance body. In this model ball bearings have been fitted throughout the transmission, and the control levers have been placed above the steering-wheel.

E^1, from the propeller-shaft. Thus the box itself forms one of the principal members in transmitting the power, although it is, of course, in no way *rigidly* connected to the live axle. From the box the power is transmitted through the spider, D^5, to the small bevel-pinions, D^6, which mesh with the bevel-wheels, C^4, on the live axle. Normally, the pinions, D^6, do not revolve about their spindles, D^5, but merely act as tie bars between the wheels, C^4. Whenever the car is travelling round a curve, however, the outer wheel is caused (by the car) to travel faster than the inner wheel. In consequence, the respective bevel-wheels, C^4, also revolve at different speeds, and in doing so make the pinions, D^6, rotate about their spindles, D^5. With the clutch engaged and the engine driving, this differential action has no effect on the speed of the box, D, and the increase in speed of the outer wheel is, therefore, accompanied by a corresponding decrease in speed of the inner wheel. The driving bevel pinion, E^1, is formed solid with its spindle, E, but the spindle itself is separate from the propeller-shaft, being coupled to it by a universal joint. There are two ball-bearings, E^3, placed at a considerable distance apart, behind the pinion, and an excellent feature in the construction of this gear is the provision of another ball-bearing, E^8, on the other side. This additional bearing prevents the pinion, E^1, from being "overhung"; it is not always easy, however, to find room for such a bearing inside a differential case, and in this instance it is interesting to notice that the box, D, is placed behind the bevel wheel, D^1, instead of. as is more usual, in front, by which arrangement sufficient room is available for the bracket, F^1, which supports the bearing, E^8.

(*To be continued.*)

THE EMPIRE SPRING WHEEL.



The Empire Wheel.—Three views, taken of a model, illustrating the latest design for the "heavy type" wheel. Only the centre portion of a complete wheel is shown, the outer rim, which may be of any diameter, being suitably attached by spokes or stamped "discs."

OUR readers are already familiar with the principles and general construction of the Empire spring wheel, which has been designed by Mr. A. S. F. Robinson. In a previous article we dealt very fully with the various types which had then been built, but Mr. Robinson has now evolved another pattern which, it is hardly surprising to find, embodies the leading characteristic features of the more important earlier types. This latest design is illustrated by photographs which we have taken of a small model.

Only the centre part of the wheel is represented, in which respect it may be compared with the corresponding portion of the wheel illustrated in Fig. 10, page 1297 of our issue of October 21st, 1905. Certain details of the type there described will be recognised again in this model, but, on the other hand, the trolleys, D, and the rockers, F, are both carried by the centre member, B^2, in very much the same way as they were in the earlier type, which we described and illustrated in the same issue.

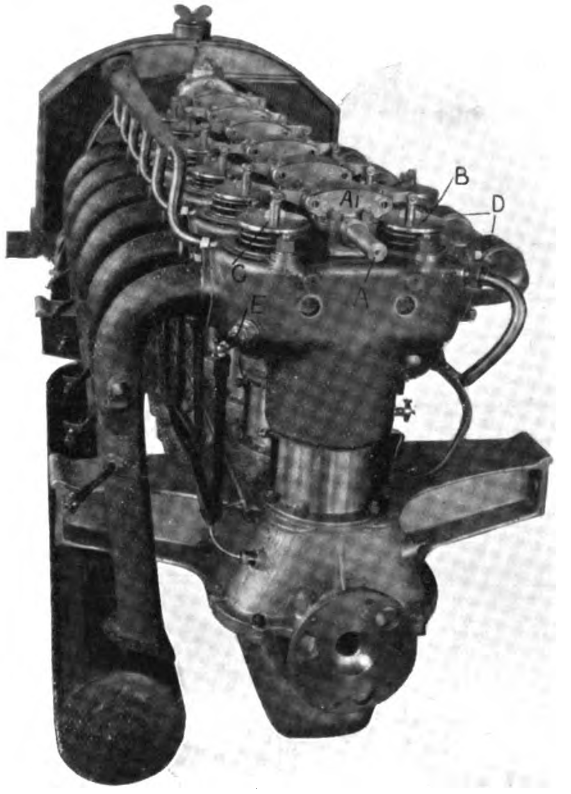
As a result, Mr. Robinson has evolved a very substantial wheel for commercial vehicles, in which the original principles are embodied in an improved form. Owing to the use of the double roller type of trolley, D, practically no side-thrust is imposed on the trolley-guide, D^3, as was the case in the type illustrated in Fig. 11 of the article already referred to, while another advantage is that the springs are no longer drilled to receive holding-down bolts, their ends are hooked over the saddle on the rocking-beams instead, to prevent their displacement. It will be noticed, too, that the compensating rockers are carried on bolts, so that the stiffness of the springs can be readily adjusted. This feature was omitted on previous models of "heavy-type" wheels, although prominent on the original touring car model first constructed.

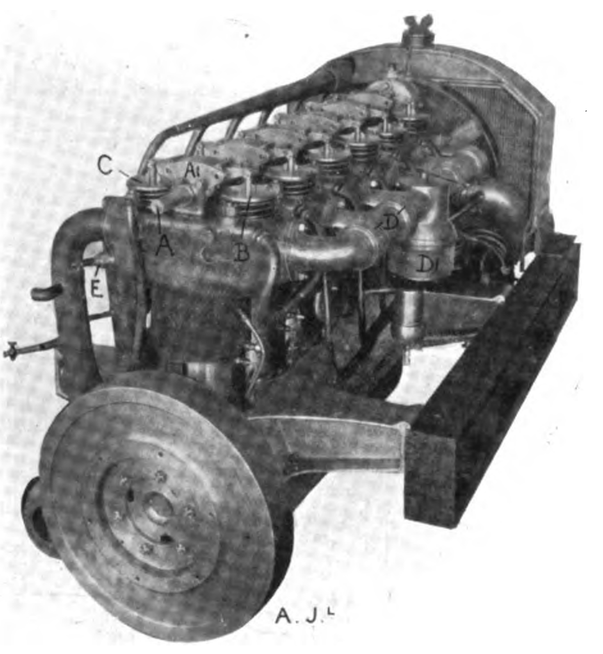
The Automobile Association

Is still further elaborating its programme. To the form of activity which has made it a familiar and useful institution to motorists generally, it is adding a propaganda for securing (1) close trimming of hedges at cross roads, (2) display of the names of villages and hamlets at each end thereof, and (3) restoration and improvement of unsatisfactory direction posts, while in addition they are establishing a confidential information bureau referring to every main trunk road. The importance of these new departures for automobilists speak for themselves, and the Association is certainly to be congratulated on its enterprise and energy.

SIX-CYLINDER MERCEDES ENGINES.

THERE are many reasons why the powerful 6-cylinder engines, built for the latest Mercedes racers, should be particularly interesting to our readers, for not only is it significant that the 6-cylinder principle should have been adopted by this celebrated firm on their racing cars, but these new engines are of a totally different design in many important respects from any previous Mercedes models. The three cars which are to represent the Cannstatt Daimler Company in the Sarthe Circuit for the Grand Prix next June are fitted with engines of this type, while we also understand that Mr. W. K. Vanderbilt also intends to acquire one for competing in American racing events this year.





The accompanying illustrations, which have been prepared from original photographs kindly sent to us by the editor of the *Allgemeine Automobil-Zeitung*, of Vienna, show one of these engines from two different points of view; that on the left—with the fly-wheel removed—enables the exhaust-valve side to be seen, while, in the other photograph, the carburettor is prominent on the other side. In both cases, the honeycomb radiator—which is made of steel—is seen fixed in place at the front end of the engine, but, except on the extreme right, the test-bench on which the engine was resting has been cut away by us for the sake of clearness.

Quite the most noticeable departure from previous Mercedes practice is the arrangement of the cam-shaft, A, centrally above the cylinders, somewhat in the same manner that has for some time been customary on the well-known Maudslay engines that are built in Coventry. It is, moreover, driven through an intermediate vertical shaft, that passes up from the front end of the crank-shaft, with the interposed gear-wheels enclosed in oil-tight cases. The inlet, B, and exhaust-valves, C, do not, however, lie beneath the cam-shaft, for, except that they are slightly nearer together than usual (and are, of course, inverted), they occupy much their orthodox positions in valve-chambers that project on each side of the cylinder heads. Their operating cams are enclosed in neat casings, A^1, that also serve the duty of supporting the short pivoted rock-levers, and each valve is held down in place from above by a pair of studs and nuts.

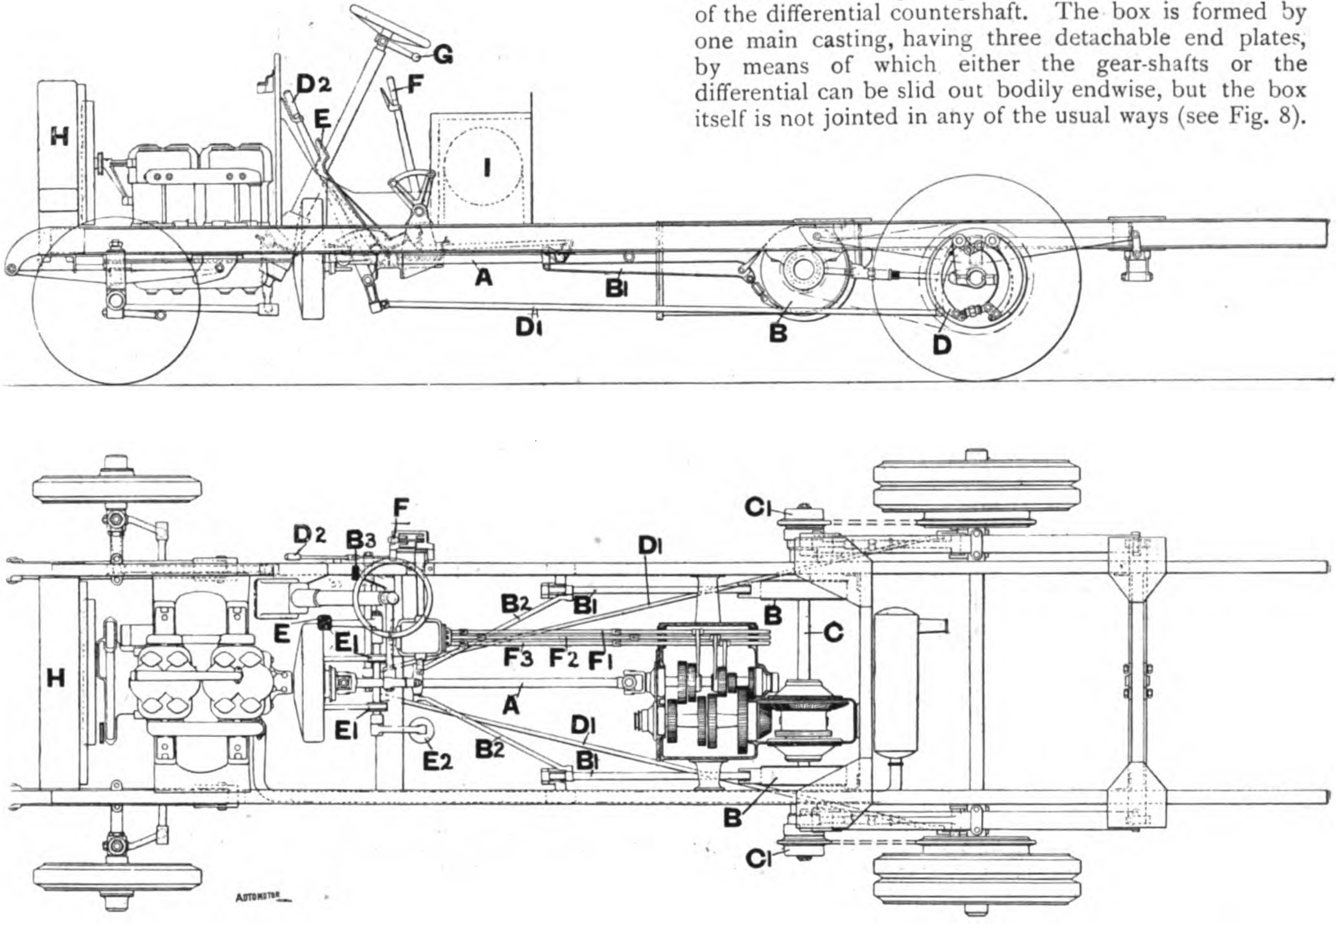
Concerning the actual constructional details of the cylinders we are not at present able to speak with certainty, but we understand that each cylinder is machined out of a billet of special steel, and that the cylinder-heads, together with the water-jackets, are steel castings. Each cylinder is, it will be observed, bolted independently to the crank-chamber, the upper portion of which has four projecting feet for direct attachment to the chassis. The cylinders have a bore of 160 mm., and a stroke of 150 mm., so that the actual power available is probably about 135 to 145 b.h.p.

One carburettor, D^1, serves for all the cylinders, but special provision is made for preventing the long, straight induction pipe from imposing any twisting strains on the cylinders when they become heated, for there are concertina-like expansion joints, D, introduced in it between cylinder and cylinder. On the other side, separate exhaust-pipes are led to a cylindrical silencer beneath.

All the gear-driven parts—the magneto, the pump, and the vertical shaft—are arranged at the front of the engine, as also is the fan which draws air through the radiator. Remarkable, in its way, is the fact that the Simms-Bosch magneto is of the high-tension type, used in conjunction with the jump-spark ignition-plugs, E, for hitherto a low-tension system has always been a feature of all Mercedes engines.

THE CRITCHLEY-NORRIS PETROL 'BUS.

ANOTHER entirely new make of motor 'bus—of British manufacture throughout—is now appearing on the market for the first time, and is to be brought before the notice of the public at the Agricultural Hall Show that opens to-day (Saturday). In many important respects it differs from any of the motor 'buses now in use, for its designers, Mr. J. S. Critchley, M.I.M.E., and Mr. W. Norris, M.I.M.E., A.M.I.C.E., have not merely contented themselves with incorporating the best features of other vehicles, but have also adopted some distinctly novel characteristics of their own. They have recently acquired and equipped large works at Bamber Bridge, near Preston, and—as the Critchley-Norris Motor Company (a branch of Messrs. Peter Pilkington, Limited)—are already turning out these heavy vehicles for commercial purposes. Incidentally, it may be added that they also intend to manufacture pleasure cars, and that in all cases their vehicles are to be fitted with the well-known Crossley engines, which, it will be remembered, are also built to the designs of Mr. Critchley.



Figs. 1 and 2.—Side elevation and plan of the Critchley-Norris Motor 'Bus Chassis, showing the general arrangement of the entire mechanism.

The motor 'bus chassis, of which we are now able to give full particulars, has been so designed that either the 30-h.p. or the 40-h.p. engine—both of which were described in our issue of February 3rd last—can be fitted, and one of the chief objects of the designers has been to ensure accessibility throughout the entire transmission mechanism. Special care has, moreover, been taken in the selection of suitable material for each and every part, while the chassis as a whole, with its massive channel-steel frame, is decidedly substantial.

Special Features.

Briefly enumerating the more unusual characteristics of this chain-driven vehicle, for the benefit of those who do not wish to follow us into a closer study of its many interesting constructional details, attention should first be directed to the 4-speed gear-box and to the arrangement of the differential countershaft. The box is formed by one main casting, having three detachable end plates, by means of which either the gear-shafts or the differential can be slid out bodily endwise, but the box itself is not jointed in any of the usual ways (see Fig. 8). Then, too, not only are all the shafts mounted in large ball-bearings, with adjustable ball-thrust collars behind each bevel-wheel, but the two facing bevel-wheels, which form a part of the differential gear, have their own ball-bearings inside the shell casting in addition to the external ball-bearings that support the shell. This novel design for the transmission gear is one of Messrs. Critchley and Norris's latest inventions, a further feature of which is that the end-bearings for the countershaft enable either half of the countershaft to be drawn out from the side of the chassis without disturbing the differential gear (see Fig. 10).

Other noticeable points in connection with the transmission, are the rubber cushions inside the sprockets, for

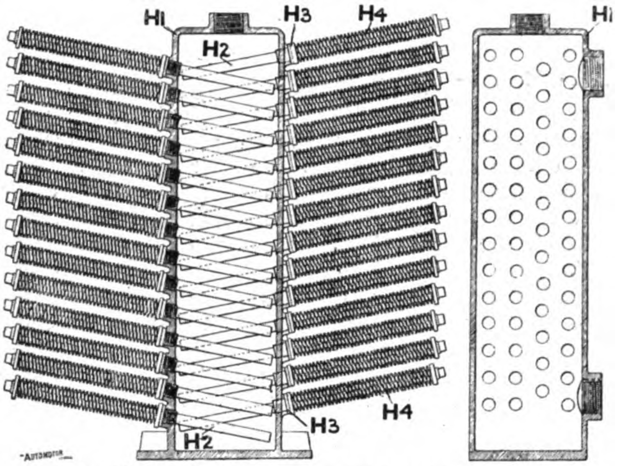


Fig. 3.—Front elevation and cross-section of the special radiator fitted to the Critchley-Norris Chassis. In this radiator each of the hermetically-sealed "Kitchen" tubes forms a separate cooling unit, so that the breakage of one tube does not materially affect the radiator, or cause any leakage of water.

giving a spring-drive action; the cone-clutch with its self-contained thrust, its cushioning dash-pot, and its substantial operating mechanism; and the compensated brakes on the two halves of the differential countershaft, in addition to the two interconnected hub-brakes.

Two or three other novel features relate more or less to the engine and its control, for not only is a very remarkable form of radiator employed, but the lubrication is effected on a new system, and a single lever serves for regulating the "time" of ignition and the throttle-valve. The radiator is built up with a number of easily replaceable sloping tubes, which project outwardly from a central water-tank through which the water is circulated. Inside the tubes themselves—and each tube is an entirely distinct unit, which, however badly damaged, does not affect the rest of the radiator—there is nothing but a small quantity of alcohol and a certain amount of rarefied air, for the tubes are sealed at both ends, and are partly exhausted by a vacuum-pump after the spirit has been introduced. The projecting portions are fitted with radiating coils for dissipating the heat rapidly to atmosphere, and the alcohol serves the purpose of quickly transmitting the heat from the circulating water to the tubes. This radiator is built to their special designs by the Critchley-Norris firm, but the "Kitchen" tubes are made by the Lune Valley Engineering Company under their own patents.

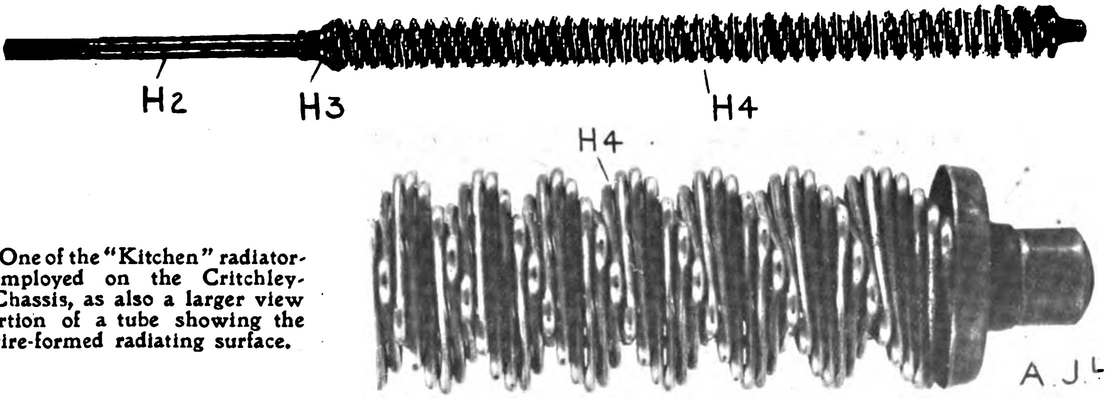

Fig. 4.—One of the "Kitchen" radiator-tubes employed on the Critchley-Norris Chassis, as also a larger view of a portion of a tube showing the neat wire-formed radiating surface.

Of the lubrication system, we are unable to give full particulars at present, but it may be said that the oil is first forced up from a supply-tank through three sight-feeds on the dashboard, and is afterwards forced down the feed-pipes to the engine by air supplied under pressure by a pump on the engine; the sight-feed glasses contain glycerine, up through which the drops of oil rise.

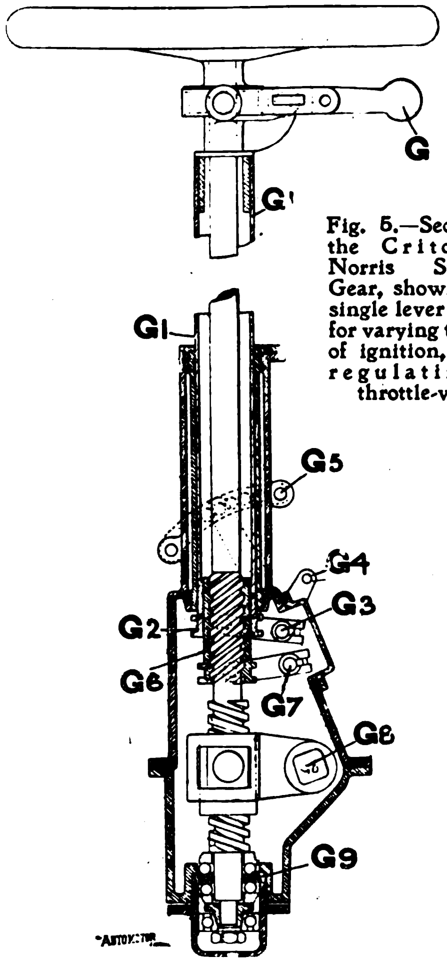

Fig. 5.—Section of the Critchley-Norris Steering-Gear, showing the single lever control for varying the time of ignition, and for regulating the throttle-valve.

For regulating the power and the speed of the engine, there is a single lever mounted on the steering-pillar, just beneath the wheel; it can be moved up or down about its pivot—thus varying the time of ignition—and it can also be moved sideways around the steering-pillar in order to open or close the throttle-valve.

Chief Dimensions.

Primarily intended to take an ordinary double-deck 'bus body, seating 16 inside and 18 outside passengers, the chassis has an overall length of 19 ft. 3 ins., with an overall width of 6 ft. 10 ins. The main frame has a channel cross-section 4¾ ins. deep by 2¼ ins. wide by

¼ in. thick, and it clears the ground by about 1 ft. 11 ins. All four wheels are made of steel, and these are shod with 5-in. solid rubber tyres—twin tyres on the 36-in. driving-wheels and single tyres on the 30-in. front wheels. From centre to centre the axles are 12 ft. 7 ins. apart (wheel-base), and from centre to centre of the rear wheels the track is 5 ft. 9 ins.

Both the 30-h.p. and the 40-h.p. engine are intended to run at a normal speed of 800 revs. per min., and the transmission-gear is so proportioned that the four forward gears then represent 3, 6, 9, and 12 miles an hour, respectively. The bore and the stroke of the smaller engine are 4¼ ins. and 5⅛ ins., respectively, and the corresponding dimensions of the larger engine are 4¾ ins. and 6 ins.

Constructional Details.

Comparatively little need be said about the general arrangement of the chassis, for this is clearly shown in the side elevation and the plan given in Figs. 1 and 2. There it will be noticed that the two channel side-members are quite straight, that they are strongly braced together by cross-members as well as by the engine and the gear-box, and that they project rearwardly some little distance behind the last cross-member. Further than this, it will be seen that an inverted transverse spring connects the rear ends of the back-springs together, that universal-joint shackles are interposed between them, and that the inner ends of all four side-springs are attached to the main-frame by sliding guide-blocks instead of by swinging links. Both the engine and the gear-box are fixed direct across the frame, the former having specially-shaped brackets bolted to the side-members in order to receive the projecting feet of the crank-chamber, and the latter being secured in a similar manner at each side as well as by a third fixing at the back to a cross-member. Of the change-speed-gear, the differential countershaft, and the main clutch, we shall have more to say presently, but in Figs. 1 and 2 it may be noted that a long propeller-shaft, A, with universal joints at both ends, connects the clutch with the change-speed-gear; that the two brake-drums, B, are fixed to the differential countershaft, C; that the sprocket-wheels, C^1, have large hubs to accommodate the "spring-drive" devices inside them; that the countershaft brakes are operated by long pivoted levers, B^1, and by compensated diagonal rods, B^2, from the brake-pedal, B^3; that the internal expanding hub-brakes, D, are similarly actuated through the compensated rods, D^1, from the brake-lever, D^2; that the clutch-pedal, E, controls the clutch by means of two eccentrics, E^1; that the clutch is prevented from engaging too fiercely by the dash-pot, E^2; that the change-speed-lever, F, is arranged on the well-known "Mercedes" "gate" principle in conjunction with the three operating rods, F^1, F^2, and F^3; that the single lever, G (which controls the engine), lies immediately beneath the steering wheel; that the radiator H, occupies the usual position in front of the bonnet; and that the 20-gallon petrol tank, I, is placed beneath the driver's seat.

(*To be continued.*)

* * * *

Road Improvement in Scotland.

EVERYTHING connected with road improvement is of high interest to automobilists. Scotland has always had a good name for general progressiveness, and while a lot of fuss has been made about the various methods of road construction and dust prevention in this country, the good people of Perth have been finding out, if not a better way than any that have been proposed here, at any rate one that would seem to be thoroughly satisfactory and apparently presents the advantages of cheapness. The method to which we refer might be described as half Tarmacing the roads. We are all familiar with the old methods of putting a layer of stones on the road, a layer of dirt on the top of the stones, and sometimes a steam roller on top of that, and the wretched results of mud in winter and clouds of dust in summer which ensue. Instead of this the Perthshire experimenters have made up the road surface with metal in the ordinary way, but instead of adding thereto the ordinary dirt have levelled and smoothed it with limestone chips which have been thoroughly tarred. This process, when the road has been completed, gives, it is said, an elastic surface quite free from dust in summer and mud in winter, while the labour involved in rigidly making up the road and the upkeep of the road when made are considerably diminished. In fact, it is said that making up the road in this way is practically little, if anything, dearer than by the ordinary old-fashioned methods. It is of interest to be able to add that the Surveyor appends to his report on the experiments the statement that he found motor car traffic, which is increasing year by year in the district, did, as far as he could perceive, little harm to the roads when they were in good order and free from pools of water.

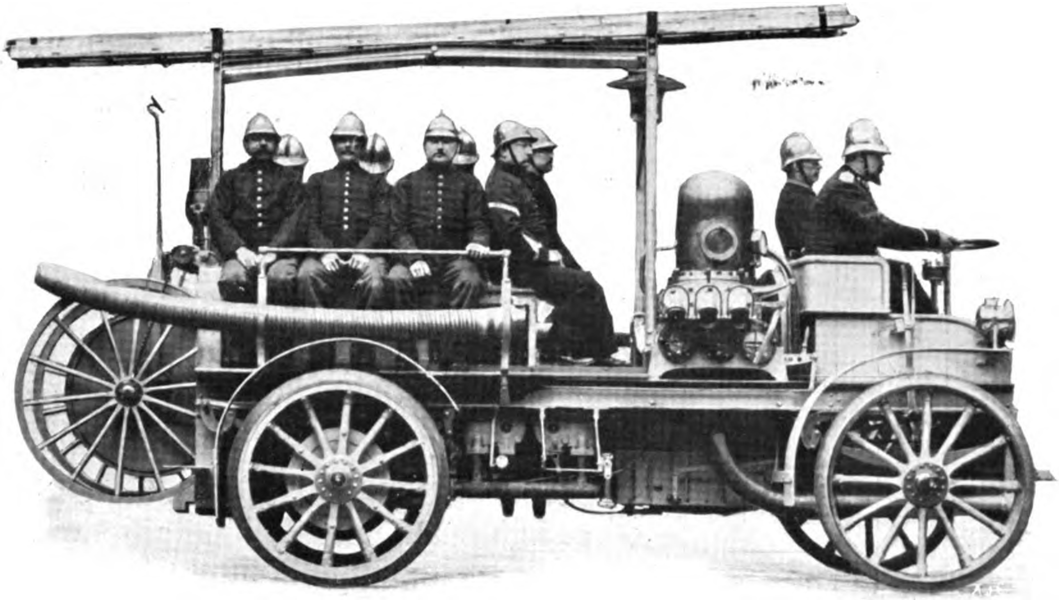
The Taxameter.

THE agitation for the introduction of the taxameter and sixpenny fares still emerges at times into the columns of the daily Press. Most people are convinced of its advantages, and are convinced that it would be a success; but the old-fashioned cab drivers will have none of it. We trust for the sake of their own prospects that the up-to-date motor cab drivers will adopt a more reasonable attitude.

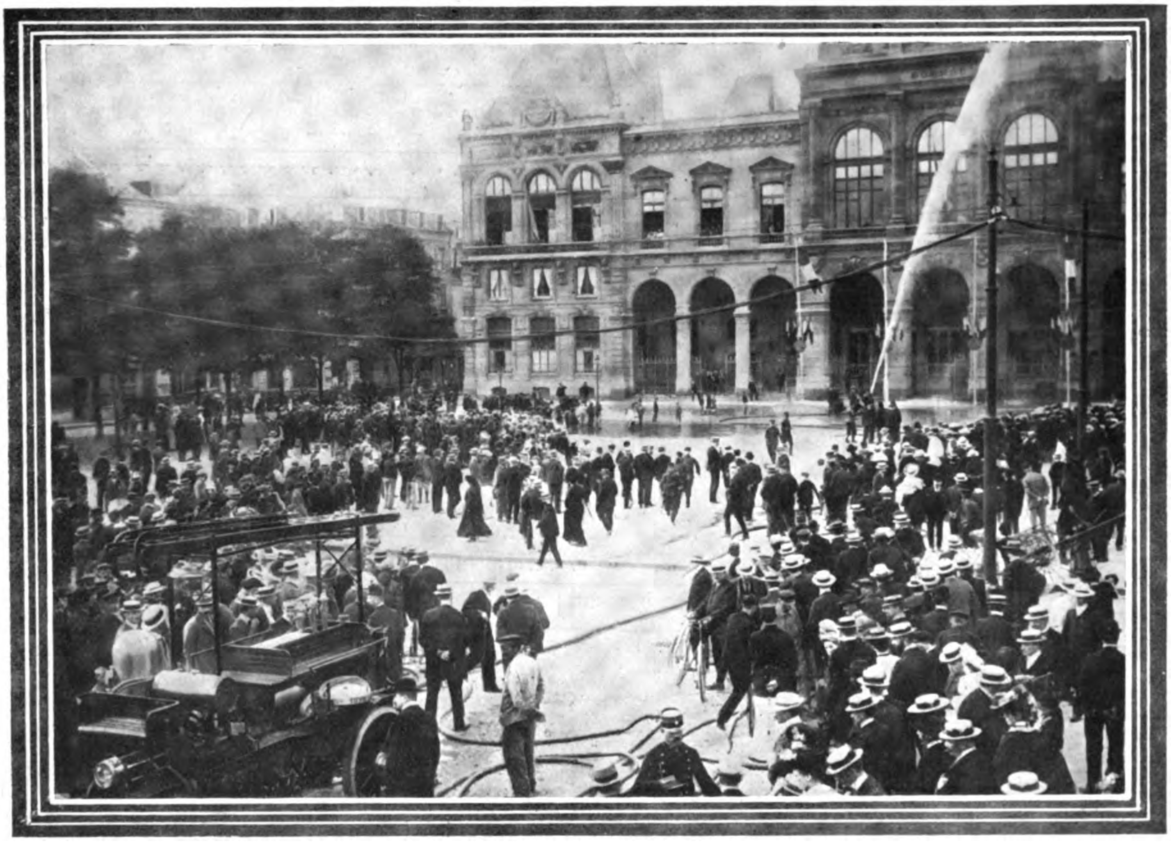
A Motor Boat Club for Glasgow.

OUR Glasgow correspondent sends us the following note:—"One of the funniest meetings at which I ever assisted was held in the secretary's office at the Glasgow Show last Saturday evening. A number of notices had been posted among the motor boat stands intimating that a meeting for the purpose of forming a motor boat club would be held, and about a dozen men, mostly in the trade, turned up. The chair was occupied by Mr. W. Scott Hayward, of Belfast, and Mr. Percy Lowcock, the agent for Gardner engines, acted as interim secretary.

There were not more than four Scotchmen present, and two of them spoke against the formation of a club other than one to be formed under the ægis of the Scottish Automobile Club, a view which was also supported by one or two of the Englishmen present. Ultimately, however, it was decided to form a branch of the British Motor Boat Club, and two or three names were given in. The curious part of the proceedings is, of course, the absurdity of a number of 'aliens' thinking that they can run a successful motor boat club in Scotland without the support of Scotsmen. The thing cannot be done."



A FRENCH PETROL FIRE ENGINE.—Quite a new type of fire engine has recently been acquired from Messrs. Thirion, pére et fils, of Paris, by the Havre authorities, this engine being equipped with a 4-cylinder petrol engine which both propels the machine from place to place and operates the pumps. As will be seen from the above illustration, this engine seats 10 men in all, besides carrying a winding drum holding 270 metres of hose, a further 180 metres beneath the back seats, an 8-metre extension ladder above, and a 1,500 litres canvas tank for the suction water. Solid rubber tyres are fitted to the road-wheels, and the change-speed-gear provides three forward speeds by means of gear-wheels which are at all times in mesh with one another.



THE HAVRE PETROL FIRE ENGINE.—After running from Paris to Havre at an average speed of 20 kiloms. (12½ miles) per hour—attaining a speed of about 34 kiloms. per hour on the level stretches—a public demonstration was given with this new fire engine, when it proved itself capable of throwing a steady stream of water upon the roof of the Bourse du Commerce, a height of over 60 metres. Our illustration shows the animated scene during the time that the various tests were in progress. The maximum capacity of the pumps was found to be 2,260 litres per minute, although nominally the delivery on each of the three speeds is supposed to be as follows: on the 1st speed (6 kiloms. per hour), 600 litres; on the 2nd speed (14 kiloms. per hour), 1,270 litres; and on the 3rd speed (22 kiloms. per hour at an engine speed of 800 revs. per min.), 2,000 litres per min.

BUYERS' GUIDE TO THE COMMERCIAL MOTOR VEHICLES (PETROL AND STEAM) OF 1906, ARRANGED IN ORDER OF PRICE. (Copyright Registered.)

NOTE.—In certain cases the information available is so meagre that we have not felt justified in including such vehicles in this table.

Buyers will find general particulars, enabling them to form a good all-round impression of each vehicle—such as price, capacity, &c.—in the left-hand columns, under the heading, "Leading Characteristics." Other useful data are included under "Constructional Details" in order to assist purchasers to obtain more minute information. Cars have been classified, primarily, as "petrol" and "steam," the former being sub-divided into heavy and light, and they have been further arranged, in each category, in order of price.

HYDRAULIC CLUTCHES—THE SPARKS-BOOTHBY CLUTCH.

(*Concluded from page* 315.)

Also mounted on the same shaft is the "inner member," B^1. This is a simple dish-shaped casting with conical sides, but it is larger in diameter than the other conical casting, A^3, which it surrounds, and thus a clearance-space is left between them to form the pump-chamber, C. Fixed inside, against the conical wall of this casting, is the stop, B^2, and on either side of this are the open port, B^3, and the grid-valve, B^4, respectively. A larger view of the grid-valve, B^4, is given in Fig. 2, and this also shows the lever, B^6, by which it is operated from the clutch-shaft, B.

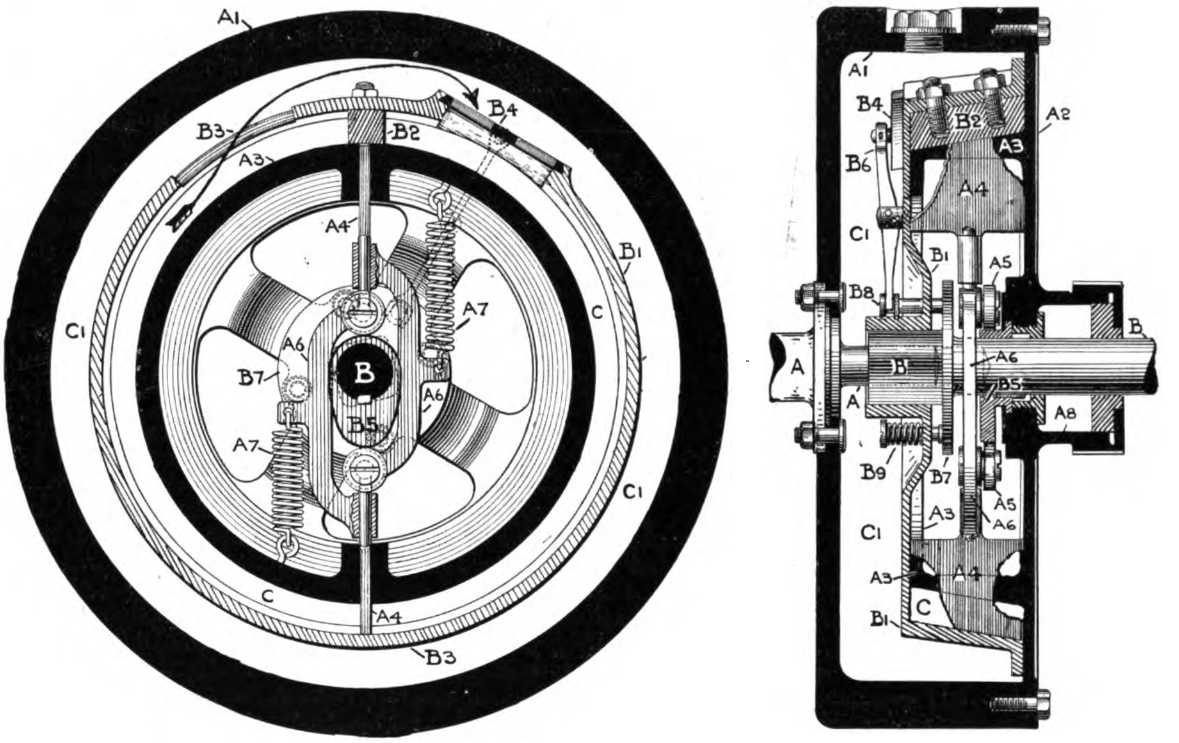

Fig. 3.—The Sparks-Boothby Clutch. Sectional drawings showing the internal construction. In both views the main portions of the engine-driven member, which include the fly-wheel, are shown in solid black.

Referring to the sectional drawing in Fig. 3, it will be noticed that the shaft, B, has a large flange, B^7, from which project pins, B^8 and B^9. Of these, the pin, B^8, forms the connection between the shaft and the lever, B^6, but the others, B^9, each carry light helical springs. These

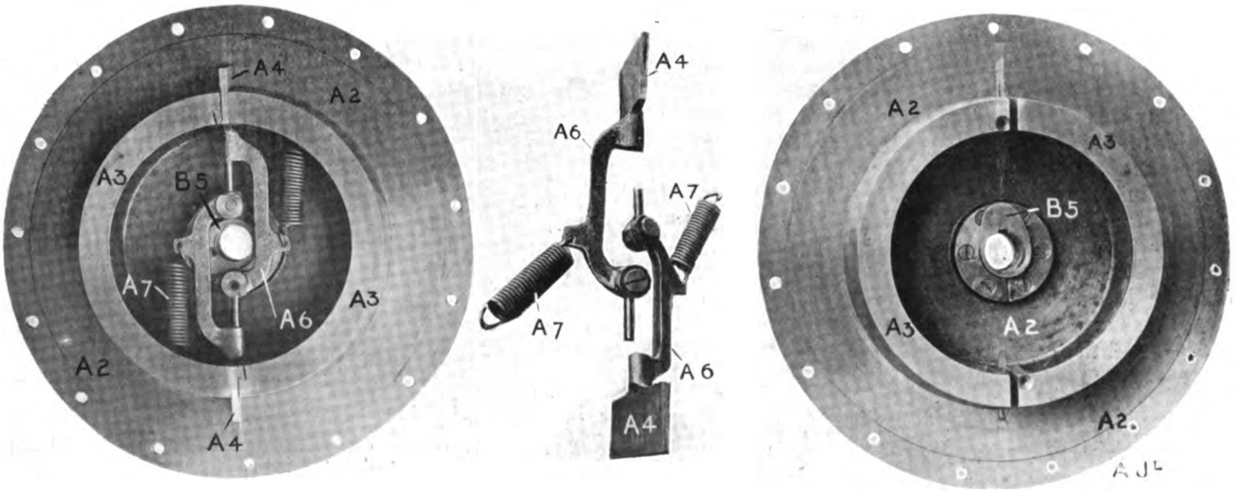

Fig. 4.—The Sparks-Boothby Clutch. Views of the main engine-driven member, A^2, which is fixed to the fly-wheel. In the left-hand illustration the paddles, A^4, by which the drive is transmitted through the medium of oil, are shown in place. In the centre, these paddles are shown separately on a larger scale, and on the right is another view of the casting, A^2, to indicate the position of the cam, B^5, which is attached to the clutch-driven shaft and operates the paddles.

springs always tend to draw the clutch-shaft, B, inwards, thus disengaging the clutch, but the action is neutralised by a much stronger external spring, which thus leaves them at all times free to maintain a light pressure on the back of the member, B¹. It will be understood that the satisfactory action of the clutch depends on being able

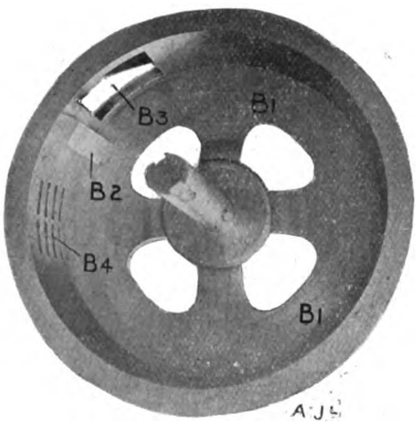

Fig. 5.—The Sparks-Boothby Clutch. View of the casting, B¹, which forms the clutch-driven member. In this illustration the position of the ports, B³ and B⁴, relatively to the stop, B² is clearly indicated.

to ensure an oil-tight contact, except when the clutch is quite free, between the flanges on the cones, A³ and B¹, and the flat faces against which they respectively press. When the clutch is slipping, these surfaces rub over each other, but still maintain virtually oil-tight joints. If these joints are broken, the pump-chamber—considered as an oil-tight vessel—ceases to exist, with the consequence that the clutch is entirely disengaged. With the force of the oil behind it, however, there is, of course, no difficulty in ensuring a good joint with reasonably accurate surfaces, but when the clutch is just being brought into engagement, it is desirable that there should already be sufficient pressure to squeeze out the oil from between these surfaces, in order to enable them to make their initial contact. It is for this purpose that the springs, B⁹, are provided. When the clutch-shaft, B, has been thrust inwards a certain distance, the flange, B⁷, comes in contact with the casting, B¹, and if the motion of the pedal be continued, it will force the two members, B¹ and A², apart, thus allowing them to run absolutely free. This latter action is not only provided in order to facilitate gear-changing, but also to avoid any tendency for the clutch to become overheated—an effect which would be introduced were the oil to be circulated for indefinite periods while the engine is running light.

In the other type of clutch, also on the market, the principle is exactly the same as with the model dealt with in this article, except that the valve is of the butterfly type, and that the castings are of a slightly different shape.

Some Early Difficulties in Design.

It is interesting to notice some of the original difficulties which presented themselves in the design of this clutch, because they explain the why and wherefore of various details in the arrangement. At first sight, for instance, it was thought that only one paddle, A, would be necessary, but one of the first drawbacks to the use of only one vane was the necessity for preventing it from striking the stop, B², when it had dispersed all the intervening oil between them. This was ingeniously overcome by mounting the paddle so that it could be actuated by a cam in the manner described, and although this arrangement overcame the initial difficulty, it immediately introduced another trouble on account of the fact that, while the paddle is passing under the stop it is no longer pressing upon the oil, and the load is therefore taken off the engine, which naturally tends to race. In order to neutralise this, two paddles were, therefore, provided—opposite one another—so that there would always be one in action. Many of the difficulties of making a clutch of this type work satisfactorily were by no means apparent during the preliminary stages of its design, and some of those met with by Mr. Sparks, who has devoted so much time to his invention, are both interesting and instructive.

One incident during the early experiments occurred with somewhat dramatic suddenness, for just as the first experimental clutch—which was of a somewhat different type—was about to be brought into engagement for the first time, it suddenly obtained a firm hold, and neither persuasion nor force was of the slightest avail in releasing it. This was hardly an encouraging beginning for an inventor engaged in the construction of a clutch in which the chief characteristic should be its pronounced softness, and capacity for slipping. In this original clutch, however, there was no valve corresponding to that in the present model, as it was at that time intended to rely upon the gradual separation of the two principal members—which were held together by the oil pressure, as they are now—to provide the required slip. Unfortunately, however, the actual values of these pressures had been under-estimated, and the result was that the force exerted by the engine on the small paddle became multiplied over the large surface of the inner clutch member by the oil. This pressure amounted to far more than any ordinary man could possibly overcome with the leverage available, so that the clutch, once engaged, was virtually stuck fast until the engine had been stopped, and the source of pressure thereby removed.

Table of Reference Letters for the Sparks-Boothby Hydraulic Clutch.

A	Driving shaft.
A¹	Fly-wheel.
A²	Face plate.
A³	Cone on A².
A⁴	Paddles
A⁵	Rollers on A⁴.
A⁶	Stays for A⁴.

Australian State Motor Car Service.

To those whom the name of the great Polish patriot has associations almost of a sacred character, the information that a motor car has been "up Kosciusko" will come as something of a shock. Kosciusko, however, is in the present instance a mountain in the southern Alps of Australia, and up it a service of motor cars is now being organised. The Colonial Government is elaborating a scheme for developing the tourist centres of New South Wales, and this scheme includes both a motor car service up the mountain, and to the Genolan Caves.

PNEUMATIC TYRES FOR MOTOR VEHICLES.

THEIR SELECTION, MANAGEMENT, REPAIR, AND MANUFACTURE.

By COLIN R. CROMBIE.—(*Concluded from page 331*).

The Manufacture of Tyres.

BEFORE dealing with the question of manufacture, I should, perhaps, say a few words concerning the preparation of the rubber which is to be used. Indiarubber is the latex which exudes like sap from certain rubber-bearing trees, and is procured by tapping trees of from eight to twelve years old and upwards, yielding from one to four pounds of rubber in the season. The rubber comes chiefly from South America and Africa, and Para rubber is now being cultivated with great success on the tea estates of Ceylon and the Straits Settlements. At present, the world consumes about 60,000 tons of rubber per annum, about 50 per cent. of which comes from Para. The best rubber, and that mostly used in the manufacture of pneumatic tyres, comes from the Amazon Valley, and is known as Para rubber—Para being the port from which it is shipped.

Crude Rubber.

On arrival at the factory, the rubber, which comes in blocks and slabs mixed with sand and vegetable matter, is cut up into small pieces and boiled in tanks, in order to assist in removing the impurities, which are sometimes considerable. I have seen what is irreverently known as "Missionary Ball," that is, a lump of clay covered with a skin of rubber, for which we have paid at the rate of 5*s*. 6*d*. per pound—evidence of the march of civilization among the native collectors.

Preliminary Treatment.

After having been boiled, the rubber is taken to the washing mills, where it is crushed into the form of a thin sheet between the corrugated surfaces of a pair of heavy rolls, a constant stream of water being played upon it so as to remove all the impurities and leave a clean sheet of partly-masticated rubber. These sheets are taken to the drying room and hung up to dry for from fourteen to twenty-one days in a temperature of about 10 to 100 degrees Fahrenheit. The rubber, after being dried, is ready for mixing with the vulcanizing and other compounds. Sulphur and litharge, or oxide of lead, are the principal vulcanizing agents employed, other ingredients being used to toughen the rubber or cheapen its quality. After being mixed in this way, the rubber, or "batch," as it is now called, is ready for calendering.

The Framework of a Tyre—the Canvas.

The first part of a tyre to be considered is the casing, which is mostly composed of cotton canvas. The cotton used is chiefly Sea Island, the next in strength being Egyptian, although some manufacturers prefer the Egyptian, as they consider it is slightly tougher and better able to stand the strain. All canvases are tested in a machine, and their breaking strain ascertained before being used on a tyre. The greatest care is required in the preparation of the canvas before it can be made into the casing. It is essential that it be bone dry, otherwise the rubber will not adhere to it. It must also be free from all size or other dressing, which would tend to weaken the fibres when exposed to the heat of vulcanization.

Impregnating with Rubber.

The web of canvas is then coated and impregnated with rubber, by a process known as friction calendering. The friction-calender used for this purpose consists of a massive framework, carrying three chilled iron rolls, which are heated by steam, the centre roll being driven at twice the speed of the other two. The rubber is fed in between the upper and centre rolls, and the canvas is passed between the centre and lower rolls. The rubber adheres in the form of a thin coating to the centre roll, owing to its higher speed and greater heat, and is thus driven by combined friction and pressure into the meshes of the canvas. The canvas is usually double-frictioned, that is to say, the rubber is applied first to one side and then to the other.

Building up the "Casing."

The canvas having thus been impregnated with rubber, is cut into strips diagonally across the piece, as nearly as possible at an angle of 45 degs., and varying in length and width according to the size of the tyre required. This is done, firstly, to enable the canvas to adapt itself to the double curve of the tyre, and, secondly, for the purpose of preventing the tyre from rolling, by having the short strands anchored on opposite sides with a direct resistance to side pull. With a straight-cut canvas there would be no such anchoring, and every strand would be free to move from side to side. The canvas has now to be stretched round on a form-block, and wrinkles which develop at the side have to be smoothed out. The number of piles of canvas employed on the casing depends on the size of tyre, but this will again be referred to later on.

The Importance of the "Bead."

The next operation is the making of the bead. Upon the regularity of the beads and their being spaced correctly—that is to say, placed at a uniform distance from each other throughout the circumference of the tyre—a good deal of the durability of the tyre, and certainly the power of staying on the rim when inflated to an enormous pressure, depends. I think I may fairly say it is at the bead that the largest number of tyres are found to be defective when it comes to having them re-treaded. This damage is sometimes caused by fitting wrong tyres to wrong rims, or by the sharp edges of rims, but most frequently by allowing water to lodge in the rim, the rust thereby formed getting at the canvas and rotting it. In a large number of cases, tyres which have been damaged in this way are quite beyond repair, as it is needless to re-tread a tyre if the canvas be insufficiently strong to carry the tread.

Avoid Rusty Rims.

In order to avoid this source of damage, tyres should be removed periodically, and the rims painted inside with a hard and flexible enamel, such as ripolin.

Forming the "Bead."

To resume—the bead is composed of a strip or cord of rubber run through a die corresponding in shape with the transverse section of the bead, and is composed, like all the rubber used in the construction of the tyre, of a vulcanizable mixing. This mixing is so compounded that when subjected to the same heat as the remainder of the tyre it becomes harder, and so gives the necessary rigidity to the bead.

Thickness of the Casing.

The strength of the tyre, as I said before, depends upon the casing, and this varies according to the number of plies of canvas employed. The standard make of tyres contain as follows:—Voiturette tyres, 3 plies of light canvas; light car tyres, 3 plies of heavy canvas; touring cars, 4 plies of heavy canvas; heavy touring cars, 5 to 6 plies of heavy canvas. These have been found to give sufficient strength to the cover and in no great degree interfere with the elasticity.

Thickness not Necessarily Strength.

As the compressed fluid air within a tyre must be reached through the solid cover, it stands to reason that the cover should be as yielding, flexible, and sensitive, as it is consistent with road wear and tear, to interfere as little as possible with the quick communication of shock to the fluid cushion. It is a mistake to suppose that many plies of canvas necessarily mean strength. To add layers of canvas is merely to defeat the object of the pneumatic tyre. The ideal tyre would be one with an outside casing ⅛-in. thick, as tough as steel, and resilient as rubber, containing the fluid air.

The Rubber and Reinforcing Canvas.

Assuming that we have now completed the casing, it is ready to receive the rubber and reinforcing canvas. The calender used in proofing the rubber sheets is similar to the friction calender before described for preparing the canvas, except that the rolls are driven at even speed. The rubber, after passing between the steam-heated rolls, is taken away on a travelling apron in sheets of the required thickness, the thickness being regulated by setting the rolls closer or further apart as may be necessary. From the calender, the rubber goes in sheets to the cutters, who cut it into the necessary strips and pass it on to the tyre makers.

Completing the Outer Cover.

The man building up the tyre puts the thin sheet of rubber on the casing from bead to bead, then come the two strips of reinforcing canvas about 2 in. wide laid on round the tyre. These stiffen and strengthen the tread, and also raise it slightly at the wearing part. In building up this part of the tyre, a great deal of care and skill are necessary on the part of the workman, as it is at this stage that the proper thickness of rubber is needed to accurately fill the mould in which the tyre has to be finally shaped and fitted.

A Tricky Operation.

All automobilists are aware of the different shapes of tyres; some have a separate tread, and others again have a tread which is moulded on, and may be either square or round on the face. It depends on the particular type on which the workman is engaged, what thickness of rubber he shall apply to the casing, and it is in this operation that one of the greatest difficulties in connection with the tyre manufacture arises.

The Vulcanizing Mould or the "Lapping."

The tyre having passed through the various processes is now complete and ready for vulcanization. It is next put into an iron mould consisting of two sections closed by hydraulic pressure, and in this position it is vulcanized. After the tyre has been vulcanized it is complete and ready for use, with the exception of the necessary trimming off of any surplus rubber which may have been forced out at the junction of the two sections of the mould. Should the tyre be of the type fitted with a separate tread, the latter is built up by itself and attached to the casing with vulcanizing solution, the whole is then put on a suitable former and lapped with a fine cambric and vulcanized, hence the cloth-mark appearing on the treads of such tyres.

The Importance of Vulcanization.

On the point of vulcanization a little information will, I think, be useful to the users of pneumatic tyres. The process of vulcanizing rubber is somewhat analagous to that of baking bread, and whilst bread will stand a good deal of toasting, the border line between toast that is fit to eat and toast that is not, is very narrow. In the same way, the border line between a properly vulcanized tyre and an over-vulcanized tyre is also very fine. Hence the danger in front of the man requiring his tyre repaired and his necessity for sending it to a firm with technical skill and a proper knowledge of the properties of rubber—qualifications that can only be gained by years of practical experience.

The Effect of Vulcanizing Rubber.

So much depends on the way in which the rubber is vulcanized that it may be interesting if at this point I say a few words on the general subject of vulcanization. The process of vulcanization, accidentally discovered by Charles Goodyear about the year 1835, may be said to have initiated the rubber industry, which is now one of the most important in the world.

Rubber in its native or pure state is imperfectly elastic, and being readily affected by heat and cold is applicable to very few industrial purposes. In a state of perfect vulcanization, however, it becomes permanently elastic, and is absolutely unaffected by any changes of temperature.

Vulcanizing—and Vulcanizing.

Broadly speaking, vulcanization consists in chemically combining sulphur with the indiarubber. This is generally carried out by mixing the two together, and subjecting the compound to heat, which may vary according to circumstances from the melting point of sulphur, at which the vulcanization commences, up to 280° Fahr., or even more. The time during which tyres are exposed to the heat may vary from two to three hours, or thereabout. The sulphur is employed either in its pure state or in the form of a metallic sulphide, but the vast array of purposes to which rubber is now put, have rendered necessary almost endless variations and modifications on the original process.

Different qualities of rubber require different treatment. Para rubber, for instance, may be thoroughly vulcanized by treatment which would be quite inadequate in the case of Congo or other African rubber. On the other hand, a vulcanizer which will thoroughly vulcanize African rubber might quite easily destroy Para rubber by over vulcanizing it. Generally speaking, rubber is more frequently spoilt by over vulcanization than by under vulcanization.

The treatment of the various descriptions of rubber, in order to prepare it for the almost endless variety of purposes to which they are put, requires not only the closest attention, but necessitates a very large amount of costly experimental work.

Not an Amateur's Process.

There are few, if any, goods in which perfect vulcanization is so essential as in pneumatic tyres. This point of vulcanization cannot be too strongly impressed upon the reader. As he doubtless knows, there are a great many tyre vulcanizers being put on the market which, according to the advertisements, are quite easily worked, and enable anyone to repair his own tyres at home without any special knowledge of the handling of rubber. But anyone who had seen as much of the repair of tyres as I have, would form a different opinion with regard to the ease with which they can be repaired. The case is somewhat similar to that of the man who sells a box of paints and says anyone can use them. Quite so; but it is only the artist or the man with skill who can get any use out of them. Many try, but few succeed.

Two Methods of Making Inner Tubes.

Dealing next with the manufacture of inner tubes, I should like to explain that these are made in two ways. In one case the mixed rubber is put into a machine somewhat similar in principle to a sausage machine. From this, it is forced through a die in the form of a tube, and passed on to a mandril, being then lapped round with a fine cloth, which holds it in form while it is being vulcanized. In the other case the sheets of mixed rubber are cut up into strips the length of the required tube, sufficiently wide to form its circumference, the mandril being lapped as before described. They are then put in the vulcanizing chamber, and "cured" by the steam method. Steam is used through all the tyre process for vulcanization. The moulded type of tube, which was put on the market about a year ago, has, I believe, been withdrawn owing to its unsatisfactory wearing qualities. It is unfortunate that of late a large number of very inferior tubes have been put on the market, the result, no doubt, of the demand for a cheap tube, with the price of raw rubber at about 5*s*. per lb. These tubes have little or no life. They lack the elasticity necessary to adjust themselves in their proper positions, and so get nipped. Their surface becomes impressed or "pitted" by contact with the canvas lining of the cover. They extend in length, and do not return to their natural position, and thus get creased and nipped when in use. In dealing with tubes, the chief points to be considered are, first, that the tube is the correct size for the cover; second, that the cover and tube are adjusted in their proper place before inflating; third, that a good supply of French chalk is put inside the cover to act as a lubricant.

Satisfactory Tubes.

So much depends on the reliability of the tube that it should be made from the best material only, that is to say, from vulcanized rubber possessing the maximum of toughness and elasticity. The material of which it is composed must also be of such a nature that in the event of its being damaged by a cut or a burst, it can be repaired without the risk of being weakened at that part. The ends of the tube should be joined in such a manner that there is no risk of opening at the joint after wear, and the valve should be so inserted that there is no chance of leakage round its seat after it has been for some time in use. It is of great importance that the joining and the valve patch should project as little as possible beyond the surface of the tube, so as to minimise the risk of friction between the tube and the cover. For the same reason holes should be repaired by means of plugging and not by projecting patches. In a tube, recently brought out by my firm—the "Victoria Jointless" tube—(1) the ends are brought together and vulcanized at the joint, so as to avoid the overlapping of the one on the other, and (2) the valve-patch is put *inside* the tube so as to dispense with the usual projection on the outer surface.

* * * *

Paying for the Splendour.

SOME little time back the Surrey Joint Committee, or whatever that august body that controls the police is called, expended the sum of £50 odd on a new uniform for the Chief Constable of the County, Captain Sant. We hazarded some vain guesses at the time regarding the magnificent spectacle this official must present when arrayed in these gloriously expensive habiliments.

The results of the expenditure have been observable lately on the stretch of road between the top of Pain's Hill and Redhill, that is to say, just the other side of Cobham, on the way to Portsmouth. Here there is a fine flat stretch of road with no cross-roads opening into it, except just at the top of the hill last mentioned, and everybody has been accustomed to drive along it fairly fast without fear of causing any danger to the public. At this spot the police have organised a new trap as being the most likely stretch they could pitch upon, and quite a large amount in fines has been raked in in consequence. As the expensive uniform has probably now been paid for, perhaps the trap will fall into disuse, unless the Joint Committee have an eye on similar splendour for themselves.

RACES, RECORDS, AND TRIALS.

CANNES MOTOR MEETING.—Grigg on his 35-h.p. Daimler Car during the flying kilometre test on the flat, which he accomplished at a speed of 90 kilometres per hour. Grigg and his British-built car secured the Cannes Automobile Club Cup for the series of events organised for the touring cars.

Cannes Automobile Fortnight.

As in former years, Cannes is the scene of the opening motor meeting of the season. This very enjoyable gathering of motorists has just been concluded, the result of the chief item of the programme, viz., the series of tourist car tests, being particularly gratifying to Britishers, inasmuch as the Cannes Automobile Cup is secured by Grigg with his 35-h.p. Daimler car. The meeting opened with motor boat contests in the bay. The tourist car trial consisted of a fuel-consumption trial (1 litre), which took place in the Masque-de-Fer Square, a test of brakes on the Adrets, speed tests over the flying kilometre, and a hill climb at Antibes. The results, in which, as already mentioned, a Daimler car was triumphant, are as follows:—

	Car and Driver.	Consumption (1 litre).		Brake Test.	Flying kilom.		Hill Climb.	Points.
		Distance.	Time.					
		kil.	m.	metres.	m.	s.	passr.	
1	35-h.p. Daimler (Grigg)	4·40	13	15·0	0	40	7	196·29
2	18-h.p. Peugeot (Loubet)	8·73	23	7·65	1	1	6	190·51
3	12-h.p. Clement (Gallice)	10·37	29	12·95	1	9	5	182·23
4	18-h.p. Peugeot (Liegard)	4·31	9	8·25	0	57	6	171·09

Johannesburg to Durban.

EFFORTS are being made by the Natal Automobile Club to organise, during the coming season, a trial for cars between the above two points in South Africa, a distance of about 500 miles. If successful in their object, it should considerably help in forwarding the spread of the automobile movement in our African Colony.

Tourist Trophy Race, 1906.

THE list of first entries for this important race, which is to take place this year for the second time on September 27th, again in the Isle of Man, has been issued by the Automobile Club. These comprise the following vehicles:—

	ENTRANT.	CAR.
1.	Mr. John S. Napier	Arrol-Johnston.
2.	Mr. A. Rawlinson	Darracq.
3.	Mr. A. Rawlinson	Darracq.
4.	Hon. C. S. Rolls	Rolls-Royce.
5.	Hon. C. S. Rolls	Rolls-Royce.
6.	Mr. Warwick J. Wright	Minerva.
7.	Mr. D. Citroen	Minerva.
8.	Mr. T. B. Browne	James and Browne.
9.	Mr. C. Harman Wigan	Vinot Deguingand.
10.	Mr. John S. Napier	Arrol-Johnston.
11.	Mr. Alec Govan	Argyll.
12.	Mr. Alec Govan	Argyll.
13.	Mr. Harry Smith	Rover.
14.	Mr. Albert Brown	Brown.
15.	Mr. E. H. Lancaster	Clément.
16.	Mr. Claude Watney	Pipe.
17.	Mr. T. C. Pullinger	Humber.
18.	Mr. Edward Powell	Humber.
19.	Capt. W. E. D. Owen	Ariès.
20.	Capt. W. E. D. Owen	Ariès.
21.	Mr. R. L. Jefferson	Rover.
22.	Mr. F. Guy Lewin	Peugeot.
23.	Mr. J. Ernest Hutton	Berliet.
24.	Mr. J. D. Siddeley	Wolseley.
25.	Mr. R. R. Brown	Wolseley.
26.	Mr. J. Ernest Hutton	Berliet.

The Automobile Club are particularly anxious to again emphasise, what has been pointed out so continuously and repeatedly in THE AUTOMOTOR JOURNAL, that the popular idea of the race being one to promote economy in fuel consumption is entirely incorrect. The primary object of the club in fixing a definite allowance of fuel for a given distance is simply to limit the horse-power, and thereby the speed of the competing vehicles, thus restricting the race to a definite type of *bona fide* touring car. This was considered the best method of limiting engine power, and was chosen on account of its simplicity, after other methods had been carefully considered by the committee responsible. Needless to say, those who have followed, even in a very casual way, the series of important articles which have appeared upon the subject in THE AUTOMOTOR JOURNAL, will have fully realised the importance of bringing home to everybody interested in the automobile movement this very salient fact.

A.C.G.B.I. Tyre, Lamp, and Speedometer Trials.

DURING the week ending Saturday, March 17th, the Dennis car made non-stop runs on each day, and succeeded in completing 2,446 miles since the start.

On Thursday, 15th inst, the Vulcan and Warner speedometers completed their 2,000 miles trial without incident, and on the next day the Jones, Gratze, and Cowey instruments similarly completed their tests. These devices have been replaced by the Kirby and Elliot speed indicators and the Cowey recorder, all of which made non-stop runs.

The report on the Collier tyres for the week is as follows :—

36-inch.—4 non-stop runs. Changed rear tyre once owing to burst. Rear tyre punctured once. Car under repair during one day.

34-inch.—5 non-stop runs. Rear tyre punctured once.

815-mm. (experimental).—4 non-stop runs. Rear tyre punctured once. Car under repair during one day.

Lamps.—

Headlights.—Worsnop.—Choked pipe twice. Went out twice.

Polkey.—Went out five times. Car under repair during one day.

Tail Lamps.—Ryta and Hoult.—Went out once. Car under repair during one day.

Metallic Mirrors.—Went out twice. Car under repair during one day.

Worsnop.—Went out several times.

Pradeau Wheel Trials.

THE test of this spring-wheel has now been abandoned, as the result of another broken axle on the car to which they were fitted. From the official report issued by the club, we learn that "It happened at Gerrard's Cross, about 20 miles from London, at a quarter past eight on Wednesday evening, and since this was the second time during the trial that the car had suffered a broken rear axle, it was evident that there was some unusual cause for the mischief. The entrants discovered that the wheels were too heavy for the car to which they were fitted, and consequently withdrew from the trial."

Frome's Hill Climb.

WE are reminded by the Herefordshire A.C. that an open hill-climbing contest will take place on Frome's Hill on Thursday, May 24th, for touring cars not exceeding 35-h.p.

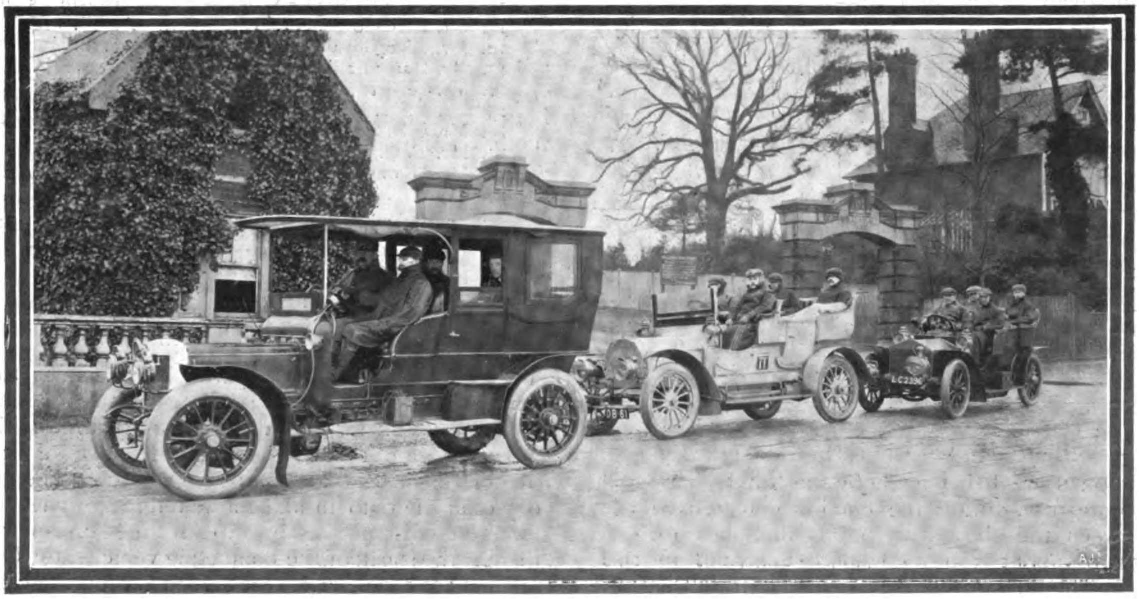
It will be remembered that this is the hill which troubled so many of the cars in the Small Car Trials. It is 1,289 yards long, and the steepest gradient is 1 in 6·37.

The contest will be held under A.C.G.B.I. rules, and the times will be taken by the official timekeepers of that body.

Entries, which close on Saturday, May 19th, should be sent to the hon. sec., Mr. Wilfred Groom. Steam cars, it is announced, are not eligible to compete.

Commercial Vehicle Trials.

ACTION has recently been taken by the Motor Van and Wagon Users' Association with a view to pushing forward the proposed trials of commercial motor vehicles, which for a long time have been under consideration by the Automobile Club. The Association are desirous that these trials should be held without further delay, and have asked the Automobile Club to consider the desirability of deputing its authority, so far as these trials are concerned, to the Motor Van and Wagon Users' Association. The matter has been, it appears, favourably considered by the Club, who have referred the question to the committee appointed to deal with these matters, with instructions to confer with the Motor Van and Wagon Users' Association with a view to arranging for the trials, and to report to the Committee of the Club at the earliest possible moment.



A.C.G.B.I. TYRE, SPEEDOMETER AND LAMP TRIALS.—The cars on the 16th day's run of these Trials near Barnet. A rainy day's experience.

Scottish Reliability Trial, 1906.

TWENTY entries have already been received for this Trial, for which the list does not close till 2nd May.

It has been pointed out that the competitors in this Trial in June, and those in the Auto-Cycle Club's end to end run, will be, to some extent, on the same roads at the same time. On June 14th both parties will have to cover the roads between Stirling and Perth. The next day—the third of the Scottish trials—the cyclists will be leaving Pillochry while the cars are making for it, and if they do not meet about Carrbridge it will be a near thing. From that point the two parties will be going farther and farther apart.

Belgian Racing Events.

THE dates fixed for the two important events organised by the Belgian A.C. are as follows:—August 13th, Circuit des Ardennes; August 18th, Coupe de Liedekerke.

Circuit Européen.

THE full text of the rules of this big Continental event have now been re-issued by the A.C. de France, after having received some slight modifications since they were first published in THE AUTOMOTOR JOURNAL some months ago. They are for all practical purposes identical with those issued in the first instance. There is an attempt in the rules to induce those interested to enter sets of tyres for official observation and awards, subject, however, to not less than five entries being received. The test, which would have to be endured under the conditions of the circuit, should be of very general interest. Since the elimination of official observers riding on the cars and taking notes of all stoppages, &c., and thereby limiting the speed within reasonable limits, racing "all out" with a view to making up time after any breakdowns will be, no doubt, the rule, and the test should therefore be a very severe one, especially on the tyres. Already entries are being lodged with the A.C. de France, the earliest including two Darracqs, two Mercedes, a Peugeot Frères car, a Wolseley, a Regina-Dixi, four De Dions, and a Dixi.

The French Grand Prix.

AT the end of last week the full regulations of the Grand Prix of the A.C. de France for racing cars, which is to take place on June 26th and 27th, were issued by the French Club. In every respect (with one exception) these agree with the details which have been published from time to time in the columns of THE AUTOMOTOR JOURNAL. The only exception is that four hours instead of three hours behind the fastest car on the first day will eliminate such car from starting on the second day in the race.

Pont-de-Gennes, about 19 kiloms. from Mans, has, as intimated originally in THE AUTOMOTOR JOURNAL some months ago, been selected as the starting point for this big race.

For the convenience of our readers we summarise below the chief points of these rules, which have from time to time been given by us as they became available.

The Sarthe Circuit is the one selected for the race on June 26th and 27th. It will occupy two consecutive days, each day about 600 kiloms. having to be covered.

A maximum of three cars only can be entered by each maker. Makers employing motors or mechanism constructed under a licence or name of any other maker, are included in this maximum of three, no allowance being made for any distinction in nationality of the make of any such car. In the event of a dispute as to which manufacturer under such circumstances shall have the
